The London Tower sample, a repair mortar of 1953, was assigned a Δ value of +5·39, which represents a ^{11}C concentration 5·39 per cent above the natural atmospheric level. A positive Δ of this magnitude must have resulted from the incorporation of artificial ^{14}C from nuclear weapons tests. The ^{14}C content of this sample is in fact identical to 1956 atmospheric activities and so must have been relatively uninfluenced by the doubling of atmospheric ^{14}C concentrations which occurred between 1954 and 1963. Although the hardening of mortar can, on occasions, require several hundred years for completion it seems that in this case the setting had reached an advanced stage within the first few years.

Of the seven samples dated, six produced ^{14}C ages significantly older than the true ages, indicating contamination by old carbon. δ^{13}C data do not seem to reveal any correlation with the extent of contamination although in theory the percentage content of limestone ($\delta^{13}\text{C} = 0$) and shell carbonate ($\delta^{13}\text{C} = -2{\cdot}5$ ‰) might be estimable by observation of the sample δ^{13}C deviation from that of carbonated lime ($\delta^{13}\text{C} = -10$ ‰). Some fractionation effects may occur, however, during carbon dioxide fixation.

An indication of the extent of contamination by old carbon may be obtained through analyses of consecutive carbon dioxide fractions released during acid hydrolysis. The amorphous carbonate from atmospheric carbon dioxide fixation appears to be hydrolysed more rapidly than the crystalline carbonate of limestone and calcareous sands. Thus the first hydrolysis fraction of Carlisle Castle mortar contained considerably less old carbon than either the second or total fractions.

Accurate ^{14}C dating of mortars therefore depends on the extent of contamination by ancient carbon. The use of calcareous sands (as against silicaceous sands) and/or incompletely kilned limestone would seem to depend on geographical location and for the British mortars studied the technique seems unreliable.

We thank the National Physical Laboratory and the Ministry of Public Building and Works for their cooperation.

BIOLOGICAL SCIENCES

Amino-acid Sequence of the Carboxyl Terminal Octapeptide of Human Haptoglobin β Chain

Haptoglobin (Hp) is an α_2-glycoprotein which exhibits the unique property of binding free haemoglobin stoichiometrically. The haemoglobin binding sites were found to be located mainly on the larger of the dissimilar polypeptide chains, the β chain[1-3]. The amino-acid sequence of the α chains has been reported[4]. We have determined the sequence of the carboxyl terminal octapeptide of the haptoglobin β chain.

Haptoglobin was purified by the method of Gordon and Bearn[2] and the β chain was isolated, after reduction and alkylation of Hp, by column chromatography using 'Sephadex *G*-200' equilibrated with 5 M guanidine HCl (ref. 5). The purified Hp β chains were subjected to enzymatic hydrolysis with trypsin or chymotrypsin, and the resulting peptides were purified by column chromatography on 'Aminex A-5' and 'AG-50W-X2' resins by the method of Jones[6].

Table 1. EDMAN DEGRADATION OF THE C-TERMINAL PEPTIDE OF Hp β CHAIN

Sequence: H_2N-Val-Glx-Lys-Thr-Ile-Ala-Glu-Asn-COOH

←——C5B——→

←——T2A——→

Lys	0·92	0·35†	0·22	**0**	0	0	0	0
Dansyl-N-terminal:	Val	Glx	Lys	Thr	Ile	Ala	Glu	Asn

Values represent residues remaining after each Edman step. Bold type indicates residues missing after each step.

* When hydrolysed with leucine aminopeptidase this residue was eluted at the position characteristic for serine, glutamine and asparagine. After acid hydrolysis the elution position shifted to that characteristic for aspartic acid. No such shift was noted for the penultimate glutamic acid.

† Lysine is often destroyed during acid hydrolysis of phenylisothiocyanate treated peptides.

One tryptic peptide, designated T2A, contained neither lysine nor arginine. Furthermore, one chymotryptic peptide of similar amino-acid composition, designated C5B, did not contain tryptophan, tyrosine, phenylalanine or leucine. Sequential analysis of these two peptides was performed by Dansyl–Edman degradation[7] and subtractive Edman degradation (Table 1). The sequences of the two peptides were identical in the terminal five positions. The chymotryptic peptide C5B contained three additional residues, lysine, glutamic acid or glutamine and valine. The Dansyl (1-dimethylaminonaphthalene-5-sulphonyl chloride) derivative of the N-terminal residue present before each degradation step was identified by polyamide plate thin-layer chromatography[8].

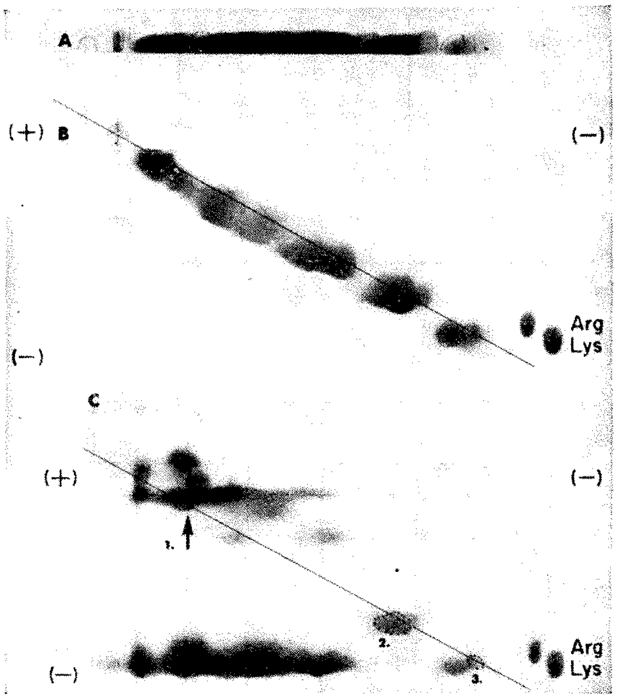

Fig. 1. Diagonal electrophoresis, *p*H 3·4 of the Hp β chain tryptic peptides. *A*, First dimension separation; *B*, second dimension separation; *C*, second dimension separation after digestion *in situ* with carboxypeptidase B.

Further evidence that this peptide is the carboxyl terminal sequence was obtained by carboxypeptidase B digestion in combination with two-dimensional high voltage electrophoresis[9]. Fig. 1 is a photograph of the diagonal electrophoresis at *p*H 3·4. After the first dimensional separation three strips were cut from the paper. One strip was stained with ninhydrin as a guide strip and appears in Fig. 1*A*. The second strip was sewn onto another paper and subjected to high voltage electrophoresis at a 90° angle and was used as a control to establish the diagonal migration pattern seen in Fig. 1*B*. The peptides contained in the third strip were digested *in situ* by spraying the strip with a solution of carboxypeptidase B (0·01 mg/ml. in 0·07 M ammonium carbonate). After 18 h in a moist chamber this strip was dried, sewn onto another paper, and subjected to second dimensional separation. The resulting pattern is shown in Fig. 1*C*.

Any peptide containing C-terminal lysine or arginine migrated off the diagonal because of the cleavage of these residues by carboxypeptidase B. The resulting free lysine or arginine also migrated off the diagonal. Three peptides unaltered by carboxypeptidase activity remained on the diagonal. These peptides were eluted from the remaining portion of the paper and further purified. The material eluted from area three was free lysine. Peptide 2 was shown to be H_2N-Thr-Pro-Lys-COOH, which proved resistant to carboxypeptidase B digestion, and had remained unaltered although it contained a C-terminal lysine. The slow migrating peptide indicated by the arrow was identical to peptide T2A.

Hydrazinolysis of three separate Hp β chain preparations failed to reveal any free amino-acids after extraction of the hydrazides. This would be expected in a protein having asparagine as the C-terminal residue as a result of the formation of the asparagine mono-hydrazide derivative.

When the C-terminal sequence of the human haptoglobin β chain is compared with the C-termini of other proteins, it is interesting that it is slightly similar to the Fc fragment (heavy chain) of IgG (ref. 10) and very similar to the C-termini of chymotrypsinogen[11] and trypsinogen[12] (Table 2). Sequential homology between the haptoglobin α chain and the κ and λ chains of Bence Jones proteins has been observed previously[4]. The striking similarity of the C-termini of the haptoglobin β chain, chymotrypsinogen and trypsinogen is surprising, and may possibly indicate a relationship of haptoglobin with the serine protease family.

Table 2. CARBOXYL TERMINAL SEQUENCE COMPARISON OF HUMAN Hp β, CHYMOTRYPSINOGEN A, TRYPSINOGEN AND HUMAN IgG H CHAIN

Hp β chain	-Val- Glx- Lys- Thr- Ile- Ala- Glu- Asn- COOH
Chymotrypsinogen A*	-*Val*- *Gln*- Gln- *Thr*- Leu- *Ala*- Ala- *Asn*- COOH

Mild "Unstable Haemoglobin Haemolytic Anaemia" caused by Haemoglobin Shepherds Bush (B74 (E18) Gly→Asp)

A 30 YEAR old South African woman of British extraction was investigated because of a persistent reticulocytosis. As a child she had been chronically anaemic, and at the age of six her spleen had been removed. After that time she had been well, but on one occasion she became "ill" after a course of sulphonamide. She was found to have a well compensated haemolytic anaemia; the haemoglobin level was 13 g/100 ml. of blood, and 5–8 per cent of her red cells were reticulocytes. Though of normal size the red cells showed target cell formation, basophilic stippling, and 75–80 per cent contained Heinz bodies. The test for abnormally heat labile haemoglobin[1] was positive. The patient's mother was found to carry the same haemoglobin abnormality but was not thought to suffer from severe haemolysis. She did, however, experience an episode of severe haemoglobinuria following sulphonamides.

The haemolysate contained 2·1 per cent Hb F as determined by alkali denaturation[2]. Paper[3] and starch gel[4] electrophoreses were used to demonstrate a higher than normal Hb A_2 fraction (3·5 per cent), a small amount (0·8 per cent) of a haemoglobin with the mobility of free α chains and a haemoglobin fraction moving more anodically than Hb A. Its separation from Hb A was incomplete by these methods, but chromatography on a 'DEAE–Sephadex' column using a *p*H gradient[5] yielded a well separated abnormal fraction amounting to 24 per cent which was subsequently used for the determination of the amino-acid substitution. On electrophoresis of the total globin in starch gel with 6·5 M urea at *p*H 8·6 (ref. 6), bands were found in the position of normal α and β chains, and in addition one band, amounting to about a quarter of the total globin, was seen which moved anodically to the β chain, indicating that the abnormal haemoglobin had an additional negative charge in the β chain. A quantitative separation of the globin chains obtained from the whole haemoglobin was made on a carboxymethyl–cellulose column in the presence of 8 M urea[7] and showed a new β chain peak, amounting to 24 per cent of the non α chains.

An unstable haemoglobin found previously at Hammersmith Hospital had already been named Hb Hammersmith[8], and the new variant has therefore been named Hb Shepherds Bush.

The purified abnormal haemoglobin fraction was converted into globin and digested with trypsin for 2 h at *p*H 8·6. The fingerprint[9,10] of the abnormal haemoglobin (Fig. 1) differed from that of Hb A by the absence of the spot representing β^ATpIX (residues 67–82 of the 146 of the β chain) and the presence of a new spot which stained for histidine[11]. It was displaced towards the anode relative to β^ATpIX and had a lower chromatographic mobility. All the other spots normally found on the fingerprint of Hb A were present in their usual positions and gave the expected specific staining reactions[11]. The insoluble "core" which remained after tryptic digestion was examined by peptic digestion and fingerprinting, but no evidence for any further abnormalities was obtained.

Table 1. AMINO-ACID COMPOSITION OF βTpIX (β67–82) OF Hb SHEPHERDS BUSH

Amino-acid	Hb SB			Hb A	Expected for β^ATpIX
Asp	3·4	3·6	3·7	3·0	3
Ser	0·9	1·5	1·25	1·0	1
Gly	1·0	1·3	1·3	2·0	2

His	1·2	1*	1*	1*	1
Yield (μmoles)	0·024	0·021	0·021	0·017	

* A lysyl is presumed to be present because the C terminal residues of tryptic peptides would either be lysyl or arginyl and the presence of arginine could be excluded by a negative staining reaction. A positive test for histidine was taken to indicate the presence of histidyl.

The peptide was isolated by preparative fingerprinting; the electrophoretic separation (1·5 h) was more prolonged than usual to ensure adequate separation from another nearby peptide (βXIIIa 121–130). Table 1 shows that the new peptide resembled β^ATpIX in composition except that it contained only one residue of glycine instead of two and approximately four residues of aspartic acid instead of three; this suggested a Gly→Asp substitution. Although asparagine also produces aspartic acid on hydrolysis, a Gly→Asn mutation would not alter the charge of βTpIX, and furthermore this substitution is not compatible with a single base change of the codons for glycine[13].

There are two glycine residues in β^ATpIX at positions 69 and 74; in Hb J Cambridge, β69 Gly–Asp[9], which is not unstable, the first of these is substituted. It therefore seemed likely that the new haemoglobin was β74 Gly→Asp, and in order to confirm this the mutant peptide was further degraded with thermolysin into smaller peptides. Thermolysin is a bacterial protease which hydrolyses peptide bonds on the amino side of amino-acids with bulky hydrophobic side chains[14–16]—for example, phenylalanine, leucine, valine and so on—but is inhibited by the

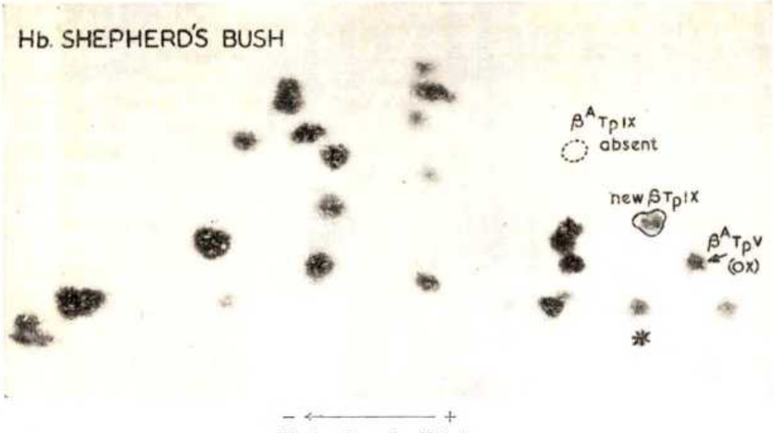

Fig. 1. Fingerprint of Hb Shepherds Bush. For details see text. An asterisk indicates the point of application.

immediate proximity of a charged amino group. Fig. 2 shows the amino-acid sequence of β^ATpIX and the expected points of thermolysin hydrolysis. Glycine 74 is in an acidic peptide which would become more acidic on substitution of glycine by aspartic acid.

Fig. 2. Sequences of normal and abnormal βTpIX and expected thermolysin peptides 1–5. Full arrows represent main sites of thermolysin hydrolysis; dotted arrows, other sites of hydrolysis. Positive and negative signs denote electric charges at pH 6·4.

The abnormal βTpIX and normal β^ATpIX were eluted from preparative fingerprints and digested with thermolysin for 3–5 h at 37° C in 0·2 M ammonium acetate buffer (pH 7·4) containing 5 mM barium acetate. The barium was removed by precipitation as the sulphate and centrifugation, and the digests were evaporated to dryness *in vacuo*. Diagnostic and preparative fingerprints of the thermolysin digests were made in the same way as for tryptic digests, and the peptides were eluted, hydrolysed and analysed.

Fig. 3 is a drawing of a fingerprint of a thermolysin digest of β^ATpIX. In the corresponding fingerprint of the abnormal βTpIX, spot 2 was absent and two new spots X and Y were present. Amino-acid analysis of X (Table 2) showed that it corresponded to the expected product of a β74 Gly→Asp substitution. Peptide Y contained chiefly serine and aspartic acid and could be derived from X by further hydrolysis. The new unstable Hb Shepherds Bush can therefore be described as $\alpha_2\beta_2$ 74 (E18) Gly→Asp.

The glycine at position β74 is the eighteenth residue of the E helix[17,18] and is at an internal site which forms part of the hydrophobic lining of the haem pocket, but is not in direct contact with the haem group[19]. Position E18 is occupied by glycine in all the mammalian β chains so far tested[20] and in the δ chain of human Hb A_2, and by alanine in the γ chain of human Hb F. The equivalent position in the α chain (α69) is occupied by alanine in human and animal α chains. Position E18 corresponds to position 75 in myoglobin and this is occupied by isoleucine in human, whale, dolphin and seal myoglobins[21,22]. In all cases the amino-acid has a nonpolar side chain. Aspartic acid is an "antihelical" residue[23]; β73 (E17) is aspartic acid in normal haemoglobin and the presence of an additional β74 (E18) aspartic acid side chain can be expected to weaken the E helix further by interfering with the carbonyl part of the preceding β70 (E14) alanine residue.

Hb Shepherds Bush represents another instance where a charged amino-acid is introduced into the haem pocket and one has to explain why this does not cause complete disruption of the structure. Examination of a scale model shows that the β carboxyl group of the aspartic acid might be drawn out of the haem pocket towards the surface of the molecule possibly to form an ionic link with histidine β77 (EF1). Similar explanations have been suggested in the cases of Hb Zürich β63 (E7) His→Arg[24] and Hb Borås β88 (F4) Leu→Arg[25]. Using his model of horse haemoglobin[26] Dr M. F. Perutz showed us why a β74 (E18) Gly→Asp mutation would be expected to make the molecule unstable: the part of the haemoglobin where E18 is situated is tightly packed and the E and F

Table 2. AMINO-ACID COMPOSITION OF THERMOLYSIN PEPTIDES: NO. 2 FROM A, AND X AND Y FROM Hb SHEPHERDS BUSH IN FIG. 3

* Phenylalanine is the N-terminal residue and is partly destroyed by ninhydrin staining.

Figures in brackets are the expected numbers of residues; those in italics are considered to represent contamination.

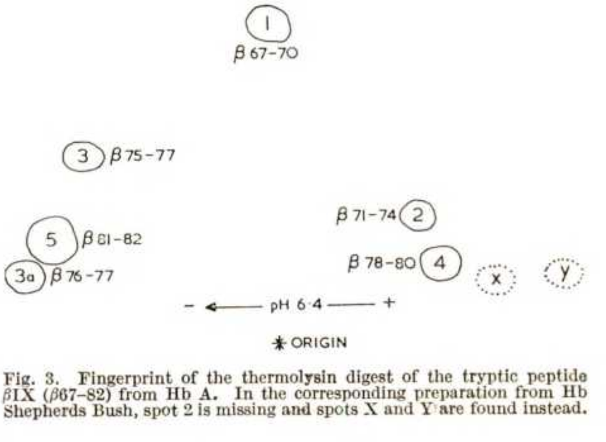

Fig. 3. Fingerprint of the thermolysin digest of the tryptic peptide βIX (β67–82) from Hb A. In the corresponding preparation from Hb Shepherds Bush, spot 2 is missing and spots X and Y are found instead.

helices are lying closely opposite each other. Although it can just accommodate an alanine instead of a glycine as in the α and γ chains, the insertion of an aspartic acid side chain at E18 in the β chain would interfere with the residues of threonine β84 (EF8) and phenylalanine β85 (F1) lying opposite and move the E and F helices apart, thereby weakening the hydrophobic forces which hold the haem pocket together.

Allotype Polymorphism of Low Density β-Lipoproteins in Pig Serum (LDLpp I, LDLpp 2)

A GREAT variety of serum antigens have been found in a number of mammalian species[1,2].

A young pig 'Chester 16-4' was injected five times at 14 day intervals with 5 ml. pooled sera of five 'Hampshire' pigs to which 1·5 ml. Freund's complete adjuvant had been added. The Ouchterlony double-diffusion technique as modified by Rapacz *et al.*[3] was used to demonstrate isoprecipitins against serum antigens. The immune serum, C16-4, gave positive reactions with three of the donor sera. The precipitation lines in the agar were clearly visible, crescent shaped and curved towards the peripheral well as shown by the band between the centre well (*A*) and peripheral well 1 (Fig. 1). This indicates that the antigen is of relatively high molecular weight. Normal sera from other pigs were tested against the antiserum, and a second band was observed in several cases, for example, the band between the centre well (*A*) and well 2 (Fig. 1). None of the three donor sera mentioned here showed this specificity. Pigs of three breeds, 397 of the Hampshire, 431 of Chester and 305 of Poland China breeds (from the University of Wisconsin Experimental swine herd), were tested. Only in the Hampshire breed were antigenic specificities found, with the frequency of 37 per cent.

The following techniques were used in an effort to identify the antigens: (1) gel chromatography separation, (2) gel immunoelectrophoresis, (3) staining with protein and lipid dyes, (4) paper electrophoresis, and (5) ultracentrifugation. Normal sera of phenotypes Lpp 1, Lpp 2 and Lpp 1,2 (Fig. 1) were fractionated on a 'Sephadex *G*-200' column. Antigen activities were restricted to the first peak supporting previous observation that the antigens are of high molecular weight. When the sera were tested by immunoelectrophoresis, the antigens were found to migrate to the α-globulin position. The stronger precipitin line stained weakly with protein reagent 'Amido Black 10*B*' and strongly with lipid stain 'Oil Red O'. The second precipitate (the one closer to the central well) stained like the first, but much less intensely. The antigens were found in the β-globulin and the β-lipoprotein position when serum samples were run on paper electrophoresis.

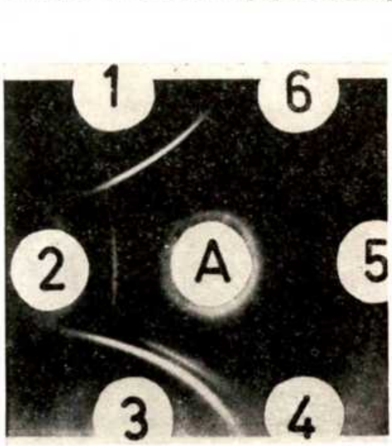

Fig. 1. Double diffusion precipitation test in agar gel. Precipitation reactions observed in this study between the immune serum placed in the centre well *A* and the normal sera placed in the peripheral wells 1–6 represent four phenotypes: Lpp 1 (reaction between *A* and 1); Lpp 2 (reaction between *A* and 2); Lpp 1,2 (reaction between *A* and 3); and Lpp 0 (lack of precipitate between *A* and 4, 5, 6).

Further identification of the lipoprotein allotypes was attempted according to the Cohen technique, using the preparative ultracentrifuge, by flotation based on selective solvent density. The antiserum reacted only with the 1·019–1·063 density material which indicates that the antigens are low density β-lipoproteins. Allotypic polymorphism of low density β-lipoproteins has been found in humans[4-8]. Absorptions were carried out to determine the relation between the antigens and to explain the unexpected presence of the second specificity in some sera. Lpp 1, Lpp 2, Lpp 1,2 and Lpp 0 are the symbols proposed for the four phenotypes observed in Fig. 1.

Absorption with all sera of Lpp 2 type removed only precipitins directed against the weaker antigen, leaving the antibodies for the stronger specificity. The Lpp 1,2 type serum absorbed all precipitating antibodies as did each Lpp 1 type serum used.

The ability of Lpp 1 serum to remove the antibodies for both types is consistent with its antigenic ability to stimulate production of both antibodies. Absorption results are evidence in support of the contention that: (1) the second low density β-lipoprotein antigen is present on the independent molecules, (2) the phenotype Lpp 1 represents the lipoprotein molecules which carry both antigenic specificities, and (3) immune serum C16-4 contains two types of isoprecipitins.

The genetic relationship between Lpp 1 and Lpp 2 became evident as a result of 179 matings, representing seven combinations, which produced 1,038 offspring. The most unequivocable result was obtained from the Lpp 1,2 × Lpp 0 mating: all offspring fell either into the Lpp 1 or the Lpp 2 allotype classes, neither parent belonging to either class. The data from all matings are consistent with the hypothesis that: (1) the allotypes Lpp 1 and Lpp 2 are controlled by codominant allelic genes which we have chosen to symbolize by *Lpp 1* and *Lpp 2*, leaving *Lpp 0* to designate the negative allele; (2) these genes seem to function independently of each other, that is, to be expressed as separate molecules; and (3) gene *Lpp 1* synthesizes two specificities, one unique to one allotype and the other common to both.

Biological Properties of Model Molecules for Vitamin B$_{12}$

CERTAIN tetradentate organo-cobalt complexes have physical and chemical properties which resemble those of vitamin B$_{12}$ (ref. 1). We have investigated whether the water-soluble complexes based on *bis*-(diacetylmonoxime-imino)-1,3-propane—abbreviated (DOH)$_2$propane (Fig. 1)—will also mimic some of the biological properties of vitamin B$_{12}$, particularly the promotion of growth in bacteria and the catalytic function of the vitamin as a coenzyme. A vitamin B$_{12}$-dependent strain of *Lactobacillus leichmanii* was used to assay the growth stimulating properties of the (DOH)$_2$propane compounds, with or without added vitamin B$_{12}$. The growth of *L. leichmanii* was only irregularly stimulated when the synthetic compounds were added to the medium alone, but in the presence of catalytic amounts of vitamin B$_{12}$ a constant stimulation was found (Fig. 2). Each compound is active in a narrow range of concentrations, with a characteristic optimum. In the series of cobalt–aquo complexes, for example, the values are 0·07 mM for the benzyl derivative, 0·4 mM for *n*-propyl and phenyl derivatives, 0·7 mM for methyl and ethyl derivatives (Fig. 2*a*).

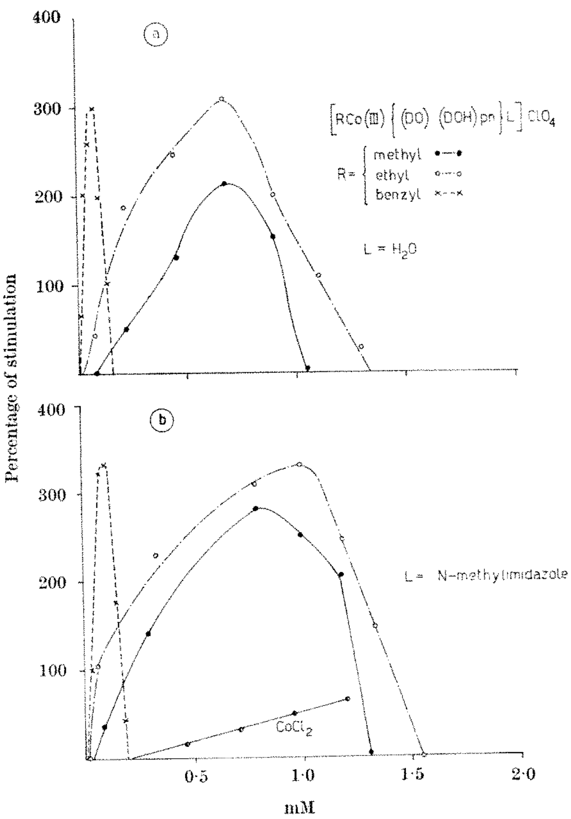

Fig. 2. Growth stimulation of a vitamin B$_{12}$-dependent strain of *L. leichmanii* by (DOH)$_2$propane compounds. Cyanocobalamin (3·6 × 10^{-12} M) was added to the assay medium. *L. leichmanii* (ATCC 7830) was grown in the LBS medium (Baltimore Biochemical Laboratories). The culture medium for the inoculum was the LBS broth. The basal medium stock solution, for the assays, was the Difco 'Bacto' B$_{12}$ assay medium. The activity of vitamin B$_{12}$ or model molecules was assayed according to the method reported in the *US Pharmacopeia*[2].

Complexes based on N-methylimidazole had virtually the same effect (Fig. 2*b*), the compound with a benzyl group being again active in the lowest concentration, at least ten times less than that for methyl or ethyl derivatives. Methyl and phenyl derivatives of the aquo-compounds, even at the optimum concentrations, are less active than the other compounds. By replacing the synthetic compounds with CoCl$_2$, all other experimental conditions being unchanged, only a negligible growth stimulation effect was observed (Fig. 2*b*).

The biochemical properties of these synthetic organo-cobalt derivatives were studied as coenzymes for bacterial propanediol dehydratase (EC 4.2.1.28) (ref. 3). We investigated whether the (DOH)$_2$propane complexes could replace the native cobamide coenzyme and also whether they otherwise influenced the enzymatic reaction. The enzyme was depleted of its native coenzyme by charcoal adsorption of a cell-free extract from *Aerobacter aerogenes* (ATCC 8724), kindly supplied by Dr Abeles, Waltham, Massachusetts. This was grown in a medium formed by: 23 mM K$_2$HPO$_4$; 7 mM KH$_2$PO$_4$; 10 mM (NH$_4$)$_2$SO$_4$; 0·8 mM MgSO$_4$·7H$_2$O; 200 mM glycerol; 54 mM propane-1,2-diol and 0·2 per cent Difco yeast extract, in deionized water. The inoculum was prepared in the same medium, but propane-1,2-diol was omitted. The bacteria were grown overnight at 37° C; harvesting and washing of cells, lyophilization, sonication and charcoal adsorption of the coenzyme were carried out as described by Lee and Abeles[4]. Sonication was performed for 1 min on aliquots of 3·5 ml. of cell suspension at 3A, 20 kHz, 0° C, using the Branson sonifier. The propanediol dehydratase activity was followed by determining propionaldehyde, the product of the reaction, as 2,4-dinitrophenylhydrazone, according to Böhme and Winkler[5]. The apoenzyme can be reassociated with the native coenzyme: a K_m value of $5{\cdot}76 \times 10^{-7}$ M has been found, using dimethylbenzimidazolylcobamide (Glaxo, Verona), in good agreement with data obtained in other laboratories[6]. One may wonder whether the term K_m is appropriate in this case because the combination of the apoenzyme with the coenzyme is practically irreversible.

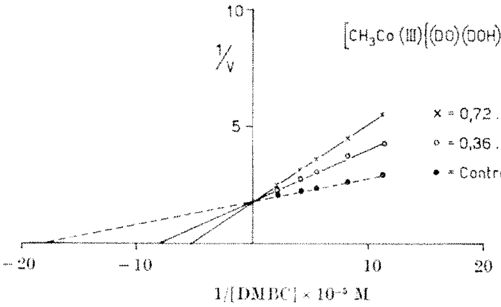

Fig. 3. Inhibition of the propanediol dehydratase activity by two different concentrations of $[CH_3Co(III)\{(DO)(DOH)propane\}H_2O]ClO_4$.

When the cobamide coenzyme was replaced by the $(DOH)_2$propane compounds the reaction was not catalysed, indicating that all compounds are inactive. All the compounds inhibited the B_{12}-coenzyme dependent propanediol dehydratase reaction and Lineweaver–Burk[7] plots indicate inhibition of the competitive type (Fig. 3). The K_i values for the different complexes are similar (Table 1). Our results open the possibility that these synthetic complexes may be promising model compounds for further studies on the mechanism of action of vitamin B_{12}.

Antitumour Polysaccharide derived Chemically from Natural Glucan (Pachyman)

WE have reported[1] that the polysaccharide lentinan obtained from *Lentinus edodes* (Berk.) Sing. (a popular edible mushroom in Japan) had a strong antitumour activity against sarcoma 180 implanted subcutaneously in mice, and that almost complete regression of the tumours had been observed after ten doses of 1 mg/kg. Lentinan is a β-(1→3)-linked linear glucan having a molecular weight of 950,000–1,050,000 according to light scattering methods.

On the other hand, pachyman[2], obtained from *Poria cocos* Wolf (Bukuryo) and hitherto considered to be a β-(1→3) linear glucan, is completely devoid of antitumour activity. Re-examination of the structure of pachyman has demonstrated, however, that the β-(1→3) chain has some β-(1→6)-linked branches. The gas chromatogram (0·75 per cent 'SE-30' on 'Gas-Chrom *Q*', 6 feet × 0·25 inch, 230° C) of the disaccharide portion, the product of partial acetolysis of pachyman, exhibited the peak for gentiobiose octaacetate, thus indicating the presence of β-(1→6)-glycoside linkages, besides that of laminaribiose octaacetate indicative of β-(1→3) glycoside linkages. The results of periodate oxidation and Smith degradation[3,4] also supported the presence of β-(1→6) linkages.

Fig. 1. Chemical conversion of pachyman to its oxidized/reduced derivative (II) and the final product of mild hydrolysis (III).

Experiments were carried out to sever the β-(1→6) linkages in pachyman by the method shown in Fig. 1 to convert it to a lentinan-like β-(1→3) linear glucan. By this conversion, a new polysaccharide with a strong antitumour activity was formed. A suspension of 3·7 g of pachyman in 450 ml. water was mixed with 150 ml. aqueous solution of 0·1 M sodium metaperiodate and stirred for 40 h in darkness at room temperature. The mixture was adjusted to *p*H 4·5 with acetic acid and centrifuged to yield a colourless paste (I). This substance was suspended in 200 ml. of water, and a solution of 800 mg of sodium borohydride in 100 ml. water was added with stirring; the mixture was stirred for 20 h to effect reduction. A further 300 mg of sodium borohydride was added and the stirring continued for another 20 h. The reaction mixture was adjusted to pH 6·0 with acetic acid and centrifuged, and the precipitate was collected, washed with ethanol and ether, and dried to 3 g of white powder (II).

This product was suspended in 200 ml. of 0·05 M sulphuric acid and stirred vigorously at room temperature for 24 h to effect mild hydrolysis. The mixture was centrifuged and the precipitate was washed consecutively with water, ethanol and ether, and dried to give 2·87 g of antitumour polysaccharide (III) having an optical rotation $[\alpha]_D^{25} + 23{\cdot}3°$ ($c = 1$, 1 M NaOH). This substance was insoluble in water but readily dissolved in alkalis, and has marked swelling properties. Its infrared spectrum lacked any absorptions corresponding to aldehyde or carboxyl groups.

Table 1. ANTITUMOUR EFFECT OF PACHYMAN, II AND III

Sample	Dose	Body weight change	Average weight of tumour (g)	Inhibition ratio (per cent)	Complete regression
Pachyman	5 mg/kg × 10	+4·4 g	6·6	0	0/8
	1 mg/kg × 10	+5·9 g	6·8	−3	0/9
	Control	+5·6 g	6·6		0/8
II	5 mg/kg × 10	+2·3 g	0·3	96	4/9
	Control	+0·9 g	6·7		0/8
III	5 mg/kg × 10	+3·3 g	0·8	88	2/6
	Control	+0·9 g	6·7		0/8

Antitumour activity was tested by the method described previously[1]. A 7 day old ascites sarcoma 180 was transplanted subcutaneously into the right groin of a Swiss albino mouse. The test sample was injected intraperitoneally once a day for 10 days starting 24 h after transplantation. The mice were killed after 5 weeks, the tumours were extirpated and weighed, and inhibition ratios were calculated and compared with the findings in control mice. Complete regression of the tumours was recorded (Table 1). Although pachyman has no antitumour activity, derivatives II and III exhibited pronounced activity, similar to that manifested by lentinan (Table 1). *Poria cocos* Wolf is one of the most important crude drugs in Japan and in other Asian countries. Pachyman is extracted from this material in a yield of about 75 per cent. The yield of II and III from pachyman is about 80 per cent. The methods seem to be the simplest and most convenient for obtaining a polysaccharide with a marked antitumour activity against transplanted tumour. Neither II nor III has any toxicity. We propose calling III "pachymaran".

The fact that such a marked difference in antitumour activity could result from a small change in fine structure, involving a small amount of β-(1→6)-linked branching or some related structural difference arising from it, is of interest with respect to the biological activities of polysaccharides in general. It is also of particular relevance to the question, raised in connexion with previous studies on antitumour polysaccharides, whether a minute amount of impurity might be the active principle. We are now studying the fine structure of pachyman, II and III, with a view to correlating structure with antitumour action in greater detail.

We thank Dr Waro Nakahara for his encouragement, and Miss Reiko Tokuzen for her cooperation.

Self-annealing of Subgroup 2 Myxovirus RNAs

THE myxoviruses of subgroup 2, Newcastle disease virus (NDV)[1] and Sendai virus[2], have been shown to contain a homogeneous component of RNA which has a sedimentation coefficient ($S_{20,w}$) of 57S, and the properties of single stranded RNA. Cells infected with these viruses synthesize viral specific RNA, 70 to 90 per cent of which anneals exclusively with virion RNA to form highly ordered complexes suggesting that most of the intracellular RNA is complementary in base sequence to virion RNA[2-4]. Several distinct components of viral specific RNA are synthesized in infected cells and one of these (57S) is indistinguishable from virion RNA in sedimentation rate[2]. The 57S RNA in infected cells has been shown to be almost completely in the form of viral nucleocapsid (C. D. Blair and W. S. R., manuscript in preparation) and annealing studies have shown that this RNA component anneals extensively when incubated with virion RNA (unpublished results of W. S. R.). Because of this observation, annealing experiments were done with 57S RNA isolated from purified Sendai virus and Newcastle disease virus, and the results I report here indicate that a large fraction of the single stranded 57S RNA from these virusesself anneals.

The L-Kansas strain of NDV and the Harris strain of Sendai virus were grown in embryonated eggs[2]. Sendai virus was labelled with $^{32}PO_4$ in embryonated eggs and NDV and Sendai viruses were labelled with ^{3}H-uridine in tissue culture[2]. The viruses were purified as previously described[3] except that the concentrated virus was incubated with pancreatic ribonuclease (10 µg/ml.) and T_1 ribonuclease (1 µg/ml.) for 30 min at room temperature to digest all RNA not protected by the virus coat, before the final sucrose gradient sedimentation. Virion RNA was extracted as previously described[3] and the 57S viral RNA was further purified by sucrose density gradient sedimentation[1]. RNA fractions from the peak of the 57S band were used for annealing experiments.

Table 1. SELF-ANNEALING OF SENDAI AND NDV RNAS

Conditions	Radioactive RNA					
	57S Sendai				57S NDV	
	^{3}H		^{32}P		^{3}H	
	C.p.m.	Per cent	C.p.m.	Per cent	C.p.m.	Per cent
Unlabelled 57S Sendai RNA added to annealing mixture						
2·0 µg	956	43	—	—	69	4·9
1·0 µg	883	40	544	22		
0·2 µg	430	19				
0	98	4·5	130	5·4		
Unlabelled 57 S NDV RNA added to annealing mixture						
0·5 µg	96	4·4	95	3·9	305	22
0·25 µg					152	11
0					77	5·5
Unlabelled 18S ribosomal RNA from uninfected cells 10 µg	102	4·5	110	4·4	71	4·9
No annealing	64	2·9	36	1·4	39	2·8
RNA heat denatured before ribonuclease	36	1·6	25	1·0	35	2·5
Total radioactivity (no ribonuclease digestion)	2,216	100	2,431	100	1,396	100

For annealing, the radioactive and unlabelled RNAs were placed in 0·3 ml. buffer containing 0·1 M Tris · HCl (pH 7·4) and 0·1 M NaCl in sealed tubes in a water bath at 95° C and the bath was slowly cooled to 37° C over 12 h. One ml. of buffer containing 0·1 M Tris · HCl (pH 7·4), 0·1 M NaCl, 0·001 M $MgCl_2$, 13 µg pancreatic ribonuclease and 1 µg T_1 ribonuclease was added to each tube for incubation at 37° C for 1 h and then the trichloroacetic acid precipitable radioactivity was determined as previously described[3].

Table 1 shows the results of annealing radioactive NDV and Sendai virus RNAs with increasing amounts of the unlabelled viral RNA. The specific activities of the ^{3}H-labelled RNAs could not be precisely determined because of the small quantities available, but they were in excess of 50,000 c.p.m. per µg so that less than 0·04 µg of ^{3}H-labelled RNA was added to any annealing reaction. Increasing amounts of ^{3}H-labelled Sendai virus RNA became resistant to ribonuclease digestion when incubated in annealing conditions with increasing amounts of unlabelled Sendai virus RNA, and the plateau or maximum amount of labelled RNA that annealed was 43 per cent of the input radioactivity. When no unlabelled RNA was added to the reaction mixture, only a small amount of self annealing occurred (4·4 per cent of the ^{3}H-RNA became resistant to ribonuclease digestion). The same level of annealing occurred in the presence of heterologous NDV or of ribosomal RNAs, which indicates that the ^{3}H-labelled Sendai RNA does not anneal to NDV or ribosomal RNA. The viral RNA which had not been annealed was almost completely digested by ribonuclease in these experimental conditions suggesting that it has a single stranded structure[5-7].

Similarly, the ^{32}P-labelled Sendai virus RNA prepared in embryonated eggs and the ^{3}H-RNA from NDV grown in tissue culture annealed specifically in the presence of unlabelled RNA from the same virus but not with RNA from the heterologous virus. In several experiments with RNA from different preparations of Sendai virus, the plateau with excess unlabelled RNA was at the level of 20 to 60 per cent annealing of the radioactive RNA and the significance of this variability is not clear.

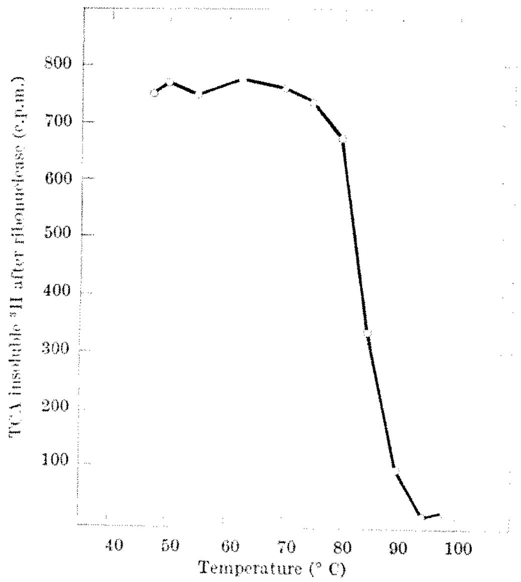

Fig. 1. Thermal transition of ribonuclease resistant product formed by self annealing viral RNA. Sendai virus RNA labelled with ^{3}H (21,000 c.p.m.) was annealed in the presence of 10 μg unlabelled Sendai virus RNA as described. The annealing mixture was then diluted 1 : 20 with water to a final salt concentration of 0·01 M. The entire solution was placed in a water bath at room temperature and the temperature increased in stages. At each of the points designated in the figure the temperature was held constant for 5 min and an aliquot of solution was removed and rapidly cooled in an ice bath. The water bath temperature was then increased. The radioactivity precipitable by trichloroacetic acid (TCA) in each aliquot after digestion with ribonuclease was determined as described in Table 1.

Fig. 1 shows the thermal transition of the ribonuclease resistant ^{3}H-RNA product of an annealing reaction with Sendai virus RNA to a ribonuclease susceptible form. The relatively sharp transition at approximately 85° C in 0·01 M salt indicates that the annealed RNA is in a highly ordered form consistent with base pairing of RNA strands with complementary base sequences[5-7].

The observation that the extent of annealing is greatly dependent on the concentration of viral RNA (Table 1) strongly suggests that intermolecular annealing rather than intramolecular annealing is occurring. This suggests that these viral RNAs consist of mixtures of two different RNA molecules which are partially or completely complementary in base sequence. The base compositions of the viral RNAs[1,2] indicate, however, that complementary sequences are not present in equal amounts.

The finding of the self annealing of these viral RNAs alters the interpretation of previous experiments showing that 70 to 90 per cent of the viral specific RNA synthesized in infected cells anneals to viral RNA[3,4]. Because both strands seem to be present in RNA recovered from virus it is not possible to determine the strandedness of the RNA synthesized in infected cells by annealing to viral RNA.

Three Types of Virus Particle in *Penicillium stoloniferum*

IT has been demonstrated recently that virus particles and double stranded viral RNA isolated from *Penicillium stoloniferum* (ATCC 14586) are potent inducers of interferon in animals[1-3]. We now report that this strain of *P. stoloniferum* contains three polyhedral viruses: two serologically distinct particles of similar size (25–30 nm diameter) and small numbers of a third larger particle (40–45 nm diameter).

Virus preparations were obtained essentially as described previously[2], either from 2 day old mycelium or 5 day old culture filtrates, and were purified by rate zonal centrifugation on 10–45 per cent sucrose density gradients at 69,000*g* for 1·2 h. Only one virus specific band was obtained. When such preparations were examined on Ouchterlony gel diffusion plates against antiserum prepared previously[2] against a partially purified virus preparation two virus specific precipitin lines were formed. Electrophoresis of such preparations either on 0·5 per cent agarose gels or 4 per cent polyacrylamide gels (containing 0·04 per cent methylene *bis*-acrylamide) using TAE buffer (0·04 M Tris, 0·05 M acetate, 0·0016 M EDTA, *p*H 8·0) resulted in the formation of two well separated virus bands (slow and fast), which could be located by staining either for protein with amido black[4] or for RNA with acridine orange[5]. The slow band was more diffuse than the fast band and showed a tendency to separate into two components (Fig. 1). That the slow band was not an aggregate of the fast band was indicated by examination of unseparated preparations in the Beckman Model 'E' analytical ultracentrifuge using the ultraviolet scanner. Two incompletely separated boundaries were observed, both having sedimentation coefficients in the range 90–110S. Greater differences in *s* values would be anticipated between monomeric and aggregated forms.

The slow and fast viruses were separated by preparative electrophoresis on columns of 0·5 per cent agarose at

pH 8·0 (0·05 M Tris-HCl buffer) using 16 V/cm for 1 h. The two virus bands, located by staining a portion of the gel as described here, were cut out and the virus particles were eluted by vigorous stirring with 0·03 M sodium phosphate buffer, pH 7·6. Viruses from each band were examined with the electron microscope using negative staining with phosphotungstic acid, and found to consist of polyhedral particles, both of similar diameter (25–30 nm). In addition, the slow virus preparation contained small numbers of larger polyhedral particles (40–45 nm diameter).

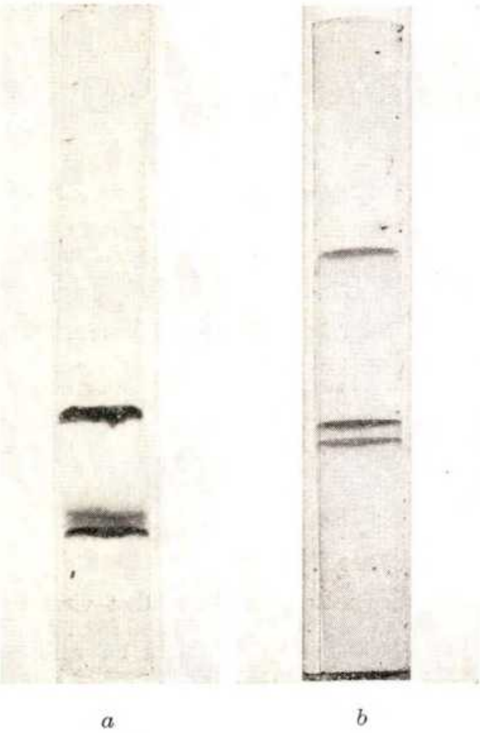

Fig. 1. Polyacrylamide gel electrophoresis in TAE buffer. Anode at top of gel. 6 mA/tube (internal diameter 5 mm). *a*, Unseparated *P. stoloniferum* virus (2·5 h) stained with amido black; *b*, RNA prepared from *a* (1·6 h) stained with acridine orange.

The two smaller viruses were serologically distinct. In gel diffusion tests, using the antiserum described here, two precipitin lines were obtained, both with the unfractionated virus preparations and with mixtures of the separated viruses. Separately the slow and fast viruses each yielded a single precipitin line. The two lines crossed over each other indicating non-identity of the two immunogens (Fig. 2). Examination of each precipitin line electron microscopically revealed the presence of only the smaller virus particles (25–30 nm diameter). The larger particles (40–45 nm diameter) did not give rise to a precipitin line with the antiserum used, and further investigation is required to determine if they are serologically related to either of the two smaller viruses.

Previous work has established that the viral RNA from *P. stoloniferum* is double stranded[2,3] with a sedimentation coefficient of 10–12S. Because this RNA was prepared without separation of the individual viruses it was suspected that it may have been a mixture. RNA prepared from the natural mixture of the three viruses by the phenol method[6] has now been examined by polyacrylamide gel electrophoresis (4 per cent acrylamide, 0·04 per cent methylene *bis*-acrylamide, TAE buffer) and found to give three principal bands (Fig. 2). Further characterization of the RNAs from the individual viruses is in progress.

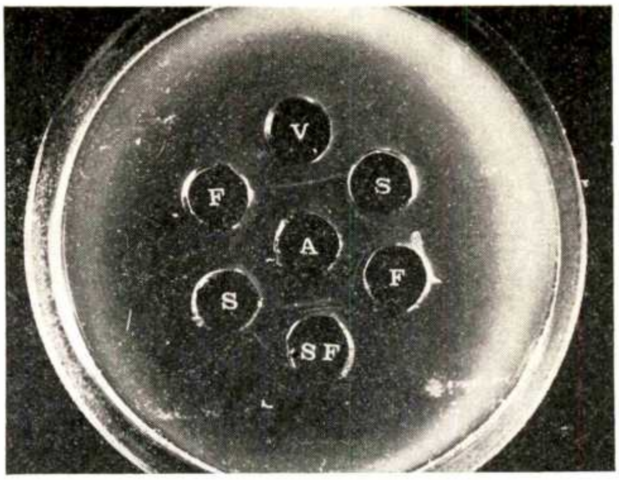

Fig. 2. Serological gel-diffusion plate. A, Antiserum; V, unseparated virus; F, fast virus; S, slow virus.

We thank Professor Sir Ernst Chain for his interest and advice, Mr G. T. Banks for pilot plant fermentations and Mrs Joan E. Darbyshire for electron microscopy.

Autoradiographic Detection of Molecular Hybrids between rRNA and DNA in Tissue Sections

WE describe here a method for DNA–RNA hybridization which permits one to localize, at the microscopical level, molecular hybrids formed between a purified ^{3}H-labelled RNA species and DNA in the cell structures of tissue sections.

Chinese hamster cells of the CHEF 125 strain were grown in monolayer cultures in Eagle's minimal essential medium supplemented with 10 per cent calf serum. In order to label the rRNA to a high specific activity, ^{3}H-5-uridine (Radiochemical Centre, Amersham, 19 Ci/mmole) was added to the cultures at 30 µCi/ml. for three generations; a half-generation chase with non-radioactive uridine followed. For the same purpose the *Escherichia coli* 500 *Hfr U*$^-$ uracil requiring strain was grown for several generations in synthetic medium[1] in the presence of ^{3}H-5-uridine (10 Ci/mmole; 20 µCi/ml.); a hundred-fold excess of non-radioactive uridine was then added for about half a generation. Hamster rRNA was extracted from total cells and purified by sucrose gradient centrifugation[2]. *E.*

coli rRNA was extracted from cells, by grinding with alumina, following the same procedure.

The hamster ^{3}H-RNA (equimolar mixture of 28S and 18S components) studied here has been tested in conventional hybridization experiments with purified DNA extracted from hamster cells. The temperature and time of incubation (65° C for 14 h) and ribonuclease treatment of the hybrids (10 μg/ml. at room temperature for 1 h) were the same as those for the hybridization experiments with tissue sections. In these conditions, saturation was reached at an RNA concentration of about 2 μg/ml.; about 0·02 per cent of the DNA was hybridized at saturation. ^{3}H-rRNA from *E. coli* hybridized negligibly with hamster DNA, but the expected level of hybridization (0·2 per cent at saturation) was obtained with DNA from *E. coli*.

To minimize the effects of the fixative on the DNA structure, golden hamster brain and liver were usually fixed for 3 h in a mixture of absolute alcohol and chloroform (2 : 1); in some cases 10 per cent acetic acid was added. The tissues were then embedded in paraffin and sectioned at 5 μm. Following removal of the paraffin and hydration, the sections were mounted on slides with glycerin–albumin or collected on membrane filters (Millipore, *GS* type, pore size 0·22 μm).

Denaturation of DNA was carried out by heating the tissue sections, on filters or slides, in SSC/10 at 100° C for 10 min (SSC = 0·15 M NaCl–0·015 M sodium citrate). Annealing was then performed at 65° C for 14 h in 2 × SSC containing 3 μg/ml. of purified ^{3}H-rRNA from Chinese hamster (1,250,000 d.p.m./μg). From then on the sections on filters were treated as described by Gillespie and Spiegelman[3] for conventional DNA–RNA hybridization. The specimens were thoroughly washed by filtration with 2 × SSC and then treated with ribonuclease (10 μg/ml.) for 1 h at room temperature in 2 × SSC. After another washing, by filtration with 6 × SSC, the specimens were air-dried and prepared for autoradiography. For sections on slides the same procedure was followed except that the washing was performed by several changes of SSC solutions. After the hybridization procedure, the sections were air-dried and the filters glued on slides. All slides were dipped in undiluted Kodak *NTB* 2 emulsion, air-dried and exposed in a dry atmosphere at 0°–4° C for periods from 20 to 60 days. Processing was carried out with Kodak *D*-19 developer. The slides were usually stained with haematoxylin. The sections, attached directly to slides, were mounted with a coverslip. The membrane filters were air-dried and clarified with immersion oil.

Microscopic examination of the autoradiographs obtained in this way revealed that most nuclei were labelled. In brain sections this labelling was chiefly restricted to the nucleolar regions (Fig. 1*C*). Neural cells are particularly suitable for this kind of observation because of the considerable size of their nuclei and nucleoli (Fig. 1*A*). Similarly, liver cells showed a grain concentration in the nucleoli (Fig. 1*D*) but silver grains sometimes appeared also in other nuclear regions. This may result from the presence of several smaller nucleoli (Fig. 1*B*) in these nuclei which are known frequently to be polyploid. In all cases the cytoplasmic labelling was very weak or absent, especially in the case of sections on filters. This is probably because the washing by filtration is more efficient. On the other hand, the nuclear labelling was greater in sections mounted on filters, probably because of the binding of the denatured DNA to the filters which might result in a decrease in the loss of DNA from sections and in less renaturation of DNA. For these reasons and for its simplicity the filter method was preferred in our experiments.

To verify that the binding of ^{3}H-RNA to the nuclear structures was the consequence of specific DNA–RNA hybridization, a heterologous radioactive rRNA (*E. coli* ^{3}H-rRNA; 1,200,000 d.p.m./μg) was used in hybridization experiments on tissue sections following the method described. Fig. 1*E* and 1*F* demonstrate that there is no labelling in the cells. Further evidence for the specificity of the hybrids obtained in tissue sections comes from competition experiments. The annealing reaction was carried out as described but in the presence of non-radioactive RNA in a ten-fold excess with respect to hamster ^{3}H-rRNA. When the non-radioactive RNA was homologous (hamster rRNA) to the radioactive RNA, the labelling of the nuclei and nucleoli was drastically diminished, while the addition of non-radioactive heterologous RNA (*E. coli* rRNA) lowered the nuclear and nucleolar labelling only slightly.

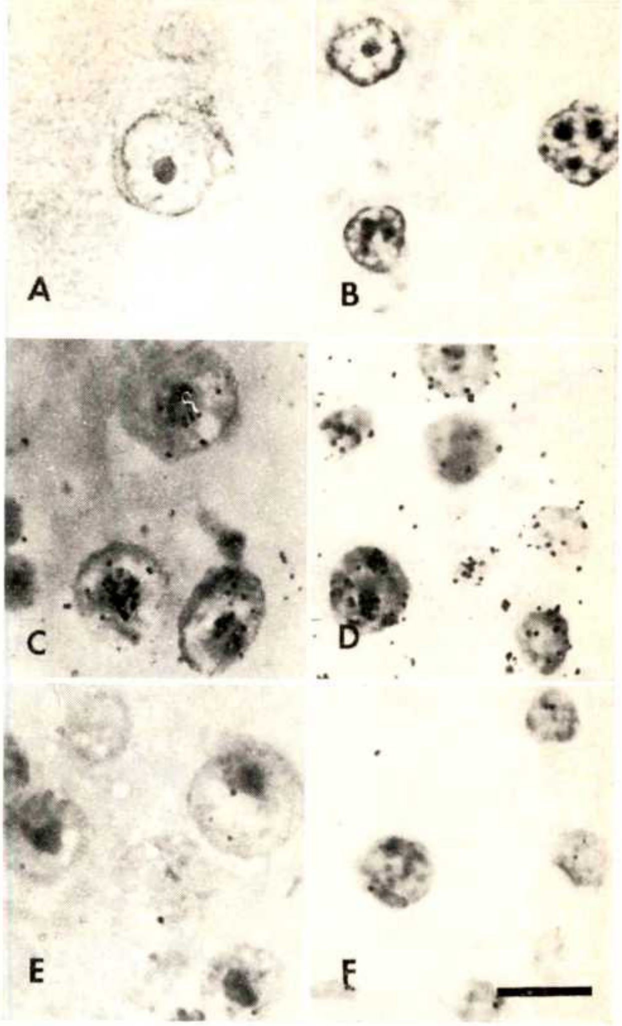

Fig. 1. Sections from hamster brain (*A*) and liver (*B*) fixed in alcohol–chloroform and stained with haematoxylin. Autoradiographs (exposure time 30 days) of brain (*C* and *E*) and liver (*D* and *F*) sections after hybridization with hamster ^{3}H-rRNA (*C* and *D*) and *E. coli* ^{3}H-rRNA (*E* and *F*). Fixation and staining as for (*A*) and (*B*). The bar represents 10 μm.

In all the experiments we have described the ribonuclease treatment following the hybridization was performed at a concentration of 10 μg/ml. at room temperature for 1 h. The suppression of this step resulted in a net increase of the grain number in the nuclei and nucleoli; a ribonuclease concentration of 100 μg/ml. (1 h at room temperature) reduced partially (30–50 per cent) the labelling as compared with the 10 μg/ml. ribonuclease treatment. In experiments with *E. coli* ^{3}H-rRNA, even in the absence of ribonuclease treatment, the grain count was at background level.

If the DNA thermal denaturation step (100° C in SSC/10 for 10 min) is omitted some hybridization still occurs on alcohol–chloroform fixed tissues. It is possible that the prolonged heating at 65° C during the annealing incubation is sufficient to loosen somewhat the DNA structure and to allow a certain degree of hybridization; a more likely explanation is that, during the histological procedure for paraffin embedding, conditions are such as to cause DNA denaturation. When there was acetic acid in the fixative solution, the hybridization seemed to be about the same with or without the thermic denaturation step, probably because of the denaturing action of acetic acid.

The number of silver grains found in hybridization experiments with hamster ^{3}H-rRNA averaged fifty per nucleus in 30 days' exposure time, when the 10 μg/ml. ribonuclease treatment was adopted. There is, however, considerable variability—from ten to ninety grains per nucleus—because only part of the nucleus is present in each section. These values are of the order of magnitude expected on the basis of the number of rRNA genes per cell, the specific activity of the ^{3}H-rRNA used and the efficiency of the autoradiographic method (about 100 grains per nucleus in 30 days' exposure time).

While this manuscript was in preparation two articles by Gall and Pardue[4] and by John, Birnstiel and Jones[5] appeared which describe similar *in situ* hybridization techniques.

We thank Professor A. Lima-de-Faria for assistance in the preparation of this manuscript.

Rare Bases in Animal DNA

The rare bases which occur in animal DNA deserve special attention because their presence is directly relevant to questions concerning the cellular, subcellular and species specificity of DNA methylation. In animal DNA, the base 5-methylcytosine (5-MeCyt) is usually detected[1,2]. Numerous attempts to find N^6-methyladenine (6-MeAde)—which is characteristic of the DNA of various microorganisms[3-5]—in animal DNA proved unsuccessful[3,6-9]. This may be accounted for by the fact that animal cells do not contain the enzymes required for methylating DNA at adenine residues[7-9]. Nevertheless, 6-MeAde and certain N^2-methylated derivatives of guanine have been recently discovered in appreciable amounts in bovine and human sperm DNA[10]. Our present knowledge on the specificity of DNA methylation in animal cells is not only scanty but also contradictory.

We report here a comparative study of the content of 5-MeCyt in the DNA of invertebrate and vertebrate animals belonging to different taxonomic groups. Further, we have studied the degree of methylation of the DNA in the sperm and different somatic tissues of the same animal. Special attention has been given to the detection of 6-MeAde in animal DNA.

DNA preparations from different cells and tissues[11,12] were hydrolysed (72 per cent $HClO_4$, 1 h, 100°) and bases were separated by paper chromatography as described earlier[4].

5-MeCyt was found in the DNA of all animals studied regardless of their taxonomic position (Table 1). The DNA of *Helix pomatia* is somewhat different from that of other molluscs[2] with respect to the content of 5-MeCyt. DNA preparations from the sperm cells of various species of sea urchin differ: the quantity of 5-MeCyt in the DNA of *Strongylocentrotus intermedius* is three-fold less than that in the DNA of *Echinus esculentus*[1]. The content of 5-MeCyt in the DNA of various species of mammals (somatic cells of rabbit and bull) also seems to be different but not so markedly. It is of interest that the DNAs of the rodents studied (rat[1], rabbit, mouse) are similar and have lower 5-MeCyt contents as compared with other mammals. A large proportion of 5-MeCyt is specific for fish DNA (about 1·5–2 moles per 100 moles).

Table 1. CONTENT OF 5-METHYLCYTOSINE IN DIFFERENT ANIMAL DNA

Source of DNA	Moles per 100 moles

N = Mean or $(\bar{x})$; σ = standard deviation or $\sigma\{x\}$; n = number of determinations.

We observe that the content of 5-MeCyt of DNA varies from 0·5 to 2 moles per 100 moles depending on the species. Taking into consideration that some insects and Crustacea have about 0·1 mole per 100 moles of 5-MeCyt in their DNA (refs. 1, 2), it may be stated that in general the degree of methylation of animal DNA differs more than twenty-fold. This favours a marked species specificity in the methylation of animal DNA. As a rule, the more distant the species are taxonomically, the greater is the difference of the proportion of 5-MeCyt in their DNA. Animal DNA is less methylated than that of higher plants[13], but in animal DNA the variability of 5-MeCyt content is much greater within a particular species. In animal DNA, 5-MeCyt occurs predominantly in Pu-m^{5}C-Pu or Pu-m^{5}C-G sequences[9,14] and is evidently concentrated chiefly in GC-rich DNA. The possibility that the observed differences in 5-MeCyt content may be ascribed not only to the specificity of DNA methylases but also to the peculiarities of the genome structure in different animals cannot therefore be entirely excluded.

Of special interest for the study of methylation specificity is the search for other rare bases in animal DNA, particularly 6-MeAde. We failed to detect 6-MeAde in hydrolysates of DNA from different invertebrate and vertebrate animals by either paper chromatography or ultraviolet spectrophotometry. We have found it only in the DNA of total sponge mass, without actually isolating individual cells from this animal: it is therefore possible that the 6-MeAde arose from the DNA of symbiotic organisms—bacteria or especially algae, which have a substantial amount of this base in their DNA (ref. 5). We did not find it in the sperm DNA of mammals (bull, boar, sheep) or fish (salmon, carp), analysing quantities of these DNA which after hydrolysis and base separation yielded up to 100 μmoles of adenine. This means that even if 6-MeAde does exist in the DNA of animals, its quantity—by contrast with the data of Unger and Venner[10]—in the sperm DNA of the bull or other mammals and fish does not exceed 0·01–0·03 moles per 100 moles of adenine.

We also tried to detect 6-MeAde in animal DNA by means of radioactivity assay. After introducing 8-^{14}C-adenine (specific activity 5·5 Ci/mole) into different animals (mouse, frog, chicken embryo) labelled adenine is incorporated into the various DNAs (up to 2×10^5 c.p.m./μmole adenine of DNA) but no appreciable radioactivity in the paper chromatographic areas corresponding to 6-MeAde and N^6-dimethyladenine was detected. Adenine is not methylated to any appreciable degree, therefore, and 5-MeCyt seems to be the only rare base found consistently in all animal DNA.

DNA preparations from different somatic cells of the same animal are similar in total base composition and degree of methylation. Nevertheless, in bovine spleen DNA the content of 5-MeCyt can vary markedly in different bulls (for example, bull I and bull III in Table 1). In bovine DNA from other organs (for example, kidney) no fluctuation in the 5-MeCyt content was observed. No individual variation in the degree of DNA methylation in spleen and other organs of the rabbit was noted. As is evident from Table 1, spleen DNA can be partially undermethylated (bull III). This might account for the fact that rat liver DNA is incapable of being methylated *in vitro* by homologous enzyme[7] whereas spleen DNA can accept methyl groups in the presence of spleen DNA methylase[8]. Generally, however, the spleen DNAs of all the animals studied so far are methylated more or less normally as compared with DNA from other tissues, in spite of the fact that spleen DNA methylase may have a very low activity[7].

Changes of degree of methylation with age, in different animal tissues, are also of interest. We find a decrease in 5-MeCyt content in the DNA of all salmon somatic tissues in the course of spawning migration[15]. No noticeable accompanying changes (including degradational ones) are evident in the primary and secondary structure of salmon DNA (ref. 16). We suggest that this decrease in 5-MeCyt during spawning migration may result from the diminution of DNA methylase activity or from the enzymatic demethylation of DNA, or both.

We have found that sperm DNA contains less 5-MeCyt as compared with that of somatic cells. This is observed regularly both in fish and mammals. The 5-MeCyt content of the sperm DNA of different mammals is similar; the 5-MeCyt/cytosine ratio in sperm cells is usually 0·037 (mean value) and in somatic cells, 0·06–0·07. A lower degree of methylation of sperm DNA as compared with that of the somatic cells of vertebrates may be explained by at least two factors: (1) sperm DNA contains fewer sequences capable of accepting methyl groups, or (2) sperm DNA is partially undermethylated. The first alternative cannot be ruled out but it is, in our opinion, less probable, because the DNA of sperm and somatic cells have practically identical total base compositions (Table 1), frequencies of different pyrimidine clusters[17] and nearest neighbour base sequences[18]. These DNA therefore have similar nucleotide sequences and closely related molecular populations. In this connexion we believe the sperm DNA of vertebrates to be partially undermethylated and that the deficiency of methyl groups is made up on or after oocyte fertilization.

Association of Murine Leukaemia Virus from a Mouse Lymphoma (2731/L) with Reovirus Type 3 Infection

STANLEY *et al.* reported the production of a lymphoma (2731/L) in Prince Henry (PH) mice after inoculation with spleen cells from a PH mouse with chronic (272 days) reovirus type 3 infection[1]. They suggested a relationship between reoviruses and the tumour. From recent data on the prevalence of murine leukaemia virus in most mouse strains[2], we would conclude that lymphomas induced in mice can, with considerable certainty, be attributed to murine leukaemia (C-type RNA) viruses in the passage materials. We have therefore tested for the presence of a murine leukaemia virus in the 2731/L tumour as well as other mouse lymphomas developing after various procedures (Table 1) in Stanley's PH line.

Primary NIH Swiss mouse embryo cells were used for tissue culture isolation; they were not found to harbour any murine leukaemia virus antigen[2]. BALB/c embryo cultures and Fisher rat embryo cultures (supplied by Microbiological Associates, Bethesda) were also used to test virus host specificity. All cells were pretreated with DEAE cellulose to increase the sensitivity of the assay[3]. The methods of inoculation and maintenance of the cultures have been previously described[2,4]. Complement fixation testing for the presence of leukaemia virus antigen was conducted under the direction of Horace C. Turner[4]. Four out of five PH mouse tumours (including the 2731/L tumour), kindly provided as 10 per cent suspensions by Dr Stanley, contained a murine leukaemia virus. On one occasion the virus was detected only after a blind passage of the originally inoculated cells. No foci of alteration in the tissue culture suggesting a sarcoma virus were seen[5]. In one specimen (LA5/T) polyoma virus was also isolated and identified by specific haemagglutination inhibition testing using guinea-pig red blood cells. Neutralization experiments were done on three isolates and all were found to have Gross–AKR type specific coat (Table 1). This finding is consistent with those of Hartley *et al.* who found all naturally occurring leukaemia viruses to be members of this subgroup[2]. The host specificity of the virus is consistent with many of the Gross–AKR type isolates which grow more readily in NIH Swiss cells than in BALB/c or rat embryo cells (J. W. Hartley, W. P. Rowe, R. J. H., in preparation). One isolate, for example, had a titre more than two logs higher in NIH Swiss than in BALB/c embryo cultures. The failure of the viruses isolated from the 2731/L and 553/L specimens to grow in the BALB/c and rat embryo cells is probably the result of titres too low to become established in the more resistant cells. In none of the original specimens could reovirus type 3 be found either by haemagglutination tests, complement fixation tests, or the mouse antibody production and rat antibody production tests (performed by Drs Michael Collins and John Parker, Microbiological Associates) (J. Parker, in preparation).

Table 1. ISOLATION OF LEUKAEMIA VIRUSES FROM TUMOURS OF PH MICE

Tumour No.	Method of tumour induction	Embryo cell cultures: NIH Swiss mouse	BALB/c mouse	Fisher rat	Virus identity	Other viruses isolated
2731/L	Inoculation of spleen cells from reovirus runt	+	–	–	Gross-AKR	–
553/L	Inoculation of spleen cells from graft versus host animal	+*	–	–		–
4261/T	Reovirus type 3 infection	–	–	–		–
1175/T	Endotoxin inoculation	+	+*	+*	Gross-AKR	–
LA5/T	X-irradiation	+	+*	+*	Gross-AKR	Polyoma

* Positive only after blind passage of original tissue culture harvests.

Keast and Stanley note that 52 per cent of the PH line develop lymphomas after irradiation[6]. The isolation of a Gross–AKR type leukaemia virus from one of these irradiated tumours, as well as other tumours induced in this PH line (Table 1), strongly suggests that this mouse strain does harbour a leukaemia virus. One would expect that as animals grow older, similar to the findings in BALB/c mice, they would have a greater frequency of virus detectable in the spleen[2]. It is therefore our impression that the mouse with chronic reovirus infection had by 272 days murine leukaemia virus in its spleen cells and inoculation of these cells into infant mice led to the 2731/L tumour induced by this C-type RNA virus.

The runting syndrome which accompanied the reovirus infection may have helped in the emergence of the leukaemia virus because the normal immune mechanism is affected[7]. In fact the tumours occurring in the runting mice of Schwartz and Beldotti[7] were probably also induced by a murine leukaemia virus. It is possible that reovirus type 3 played some part in activating or potentiating the leukaemia virus genome, similar to the findings reported with guaroa virus[8]. Reovirus type 3, however, has not enhanced the activity of other viruses[9]. Preliminary attempts to increase leukaemia virus production or expression in tissue culture with reovirus type 3 have been negative. Reovirus antigen present in the 2731/L tumour as reported by Stanley *et al.*[10] may then represent a latent carrier state of reovirus type 3 (ref. 8).

Histocompatibility and Human Placentation

HISTOCOMPATIBILITY antigens were recently suggested by Jones[1] to affect human placentation. His observation was based on data of maternal ABO blood groups and placental weights. The immunological disparity of the mother and her foetus was found to be associated with a relatively smaller placenta and vice versa. The expected proportion of ABO incompatible pregnancies for each maternal blood group was calculated from the ABO gene frequencies in the population[2].

Further studies on the influence of ABO incompatibility on human placentation were carried out by determining the maternal and infant ABO blood groups from 3,045 mother–child pairs. Rh-immunized mothers were excluded. These pairs were classified as ABO compatible, pseudocompatible and incompatible in primiparous and multiparous groups (Table 1). Placental and infant's birth weights and the duration of gestation were recorded. A comparison similar to that of Jones was made between maternal blood groups and placental weight.

According to the results in this series placental weights were not affected by ABO blood group compatibility or incompatibility between the mother and her child in either primiparous or multiparous groups (Table 1). No effect of ABO incompatible pregnancy on the weight of the child (Table 2) or the duration of gestation (Table 3) could be observed. Contrary to the observation of Jones, the mean placental weight of blood group O mothers was not lower than that of combined groups A, B and AB mothers (Table 4).

In human trophoblastic tumours a shift of the host's blood group distribution away from group O towards

Table 1. ABO BLOOD GROUP COMPATIBILITY AND MEAN PLACENTAL WEIGHT IN 3,030 MOTHER–CHILD PAIRS

Family	Mean placental weight (g) and No. of pairs: Compatible (O–O, A–A, B–B, AB–AB)	Pseudocompatible (A–O, B–O, AB–A, AB–B)	Incompatible (O–A, O–B, A–B, B–A, A–AB, B–AB)
Primiparae	605·7 (775)	595·4 (265)	610·9 (335)
Multiparae	630·2 (933)	635·3 (311)	635·3 (411)
Total	619·1 (1,708)	617·0 (576)	624·3 (746)

Table 2. ABO BLOOD GROUP COMPATIBILITY AND BIRTH WEIGHT OF THE CHILD IN 3,080 MOTHER–CHILD PAIRS

Family	Mean birth weight of the child (g) and No. of pairs: Compatible (O–O, A–A, B–B, AB–AB)	Pseudocompatible (A–O, B–O, AB–A, AB–B)	Incompatible (O–A, O–B, A–B, B–A, A–AB, B–AB)
Primiparae	3406·7 (771)	3416·1 (265)	3396·3 (327)
Multiparae	3546·3 (939)	3547·9 (353)	3549·5 (425)
Total	3483·4 (1,710)	3491·0 (618)	3482·9 (752)

Table 3. ABO BLOOD GROUP COMPATIBILITY AND DURATION OF GESTATION (WEEKS) IN 3,045 MOTHER–CHILD PAIRS

Family	Compatible (O–O, A–A, B–B, AB–AB)	Pseudocompatible (A–O, B–O, AB–A, AB–B)	Incompatible (O–A, O–B, A–B, B–A, A–AB, B–AB)
Primiparae	39·9 (774)	40·3 (262)	40·0 (335)
Multiparae	40·0 (922)	40·1 (345)	40·1 (407)
Total	40·0 (1,696)	40·2 (607)	40·0 (742)

Table 4. MEAN PLACENTAL WEIGHT ACCORDING TO MATERNAL ABO BLOOD GROUP

Maternal blood group	No. of cases Primiparae	No. of cases Multiparae	Mean placental weight Primiparae	Mean placental weight Multiparae
O	404	517	612·5	637·3
A	650	778	595·6*	631·0*
B	231	255	595·4*	633·0*
AB	102	138	585·1*	649·1*

* Mean placental weight of combined groups A, B and AB is 594·4 in the primiparous group and 633·6 in the multiparous group. Both values are smaller than that of the respective group O mothers.

A, B and AB has been observed[3,4] indicating a favourable influence of histocompatibility between the host and the tumour in the aetiology of the disease. The same is reflected by similarity in HL-A antigens[5] and by the elevated incidence of choriocarcinoma in women with consanguinous reproductive partners[6,7]. But in the growth of normal human trophoblast an analogous effect has not been found. An electronegative sialomucin coat on human trophoblast may protect the trophoblast from the immunological attack of the host's negatively charged lymphocytes[8].

Effect of Heparin on the Detection of Human Isoantigens by the Cytotoxicity Technique

IT has been suggested that the anticoagulant heparin might block antigenic sites or otherwise interfere with the expression of antigen–antibody interaction[1-6]. Of particular relevance is the effect of heparin on transplantation behaviour and cytotoxicity reactions in mice[7,8], and on human mixed lymphocyte cultures[9]. We have studied the possible influence of heparin on human isoantigen typing by the cytotoxicity technique.

Two human lymphoid tissue culture lines, IM-1 and RPMI 4265, were used as target cells in the cytotoxicity reactions[10]. IM-1 cells were washed twice in Eagle's medium with 10 per cent foetal bovine serum and incubated as in the procedure of Lippman[7] with 0–1,000 μg sodium heparinate (Hynson, Westcott and Dunning) per 10^6 cells in 0·3 ml. medium for 20 min at 37° C. The cells were washed twice in fresh medium and then mixed with serial two-fold dilutions of serum Kessinger, which recognizes HL-A 7 and other antigens (P. I. Terasaki and G. N. R., unpublished data). The cytotoxic activity of the serum was determined, using trypan blue dye exclusion as the criterion of cell lysis[11]. An endpoint titre of 15 per cent greater cytotoxicity than the complement control was taken as positive[12]. The titres obtained (Table 1) were all quite similar and bore no obvious relationship to heparin concentration.

The results were confirmed using RPMI 4265 target cells incubated with sodium heparinate in solution (Upjohn), serum Christiansen to recognize 4a and other antigens (P. I. Terasaki and G. N. R., unpublished data) and ^{51}Cr release[12] as the measure of cytotoxicity. Titres were again similar (Table 1), and were without relation to the amount of heparin used. The results failed to demonstrate blocking of the cytotoxicity reaction.

The effects of heparin were also tested in the conditions used for HL-A typing of human peripheral lymphocytes. Two normal individuals, whose lymphocytes had been previously HL-A typed using a microcytotoxicity technique[13], were selected and retyped twice, using 2,000 USP units of heparin per 10 ml. of blood (200 units are normally used) in the first instance and defibrination in the other (Table 2). In both conditions, the same specificities were recognized as in the original assay. No previously recognized specificities were blocked by ten times the usual heparin dose.

Table 1. EFFECT OF HEPARIN ON CYTOTOXIC ANTIBODY TITRES

Heparin incubated with 1×10^6 cells (μg)	Cytotoxic titre* Serum Kessinger versus IM-1 cells	Cytotoxic titre* Serum Christiansen versus RPMI 4265 cells
0	11	10
10	12	14
30	13	14
100	18	11
300	11	9
1,000	10	10

* Reciprocal of dilution giving 15 per cent or more greater cytotoxicity than a control containing complement but no test serum.

Table 2. COMPARISON OF HL-A SPECIFICITIES RECOGNIZED ON LYMPHOCYTES OBTAINED FROM PERIPHERAL BLOOD ANTICOAGULATED BY DEFIBRINATION OR BY HEPARIN

	Anderson	Lc 20	25	35
	Normal human serum	—	5	5

* Several antisera in addition to those listed were used in determining these specificities, with similar results.

Lippman's work[7,8] in a variety of mouse systems suggested that heparin might block antigen–antibody interactions. Untreated mouse L cells were rejected by host animals in doses as high as 10^9 cells, but 10^5 heparin-treated cells grew into large, metastasizing transplantable tumours[8]. Moloney tumour cells in allogenic hosts behaved similarly[7]. Lippman also demonstrated that treatment of Moloney target cells with heparin inhibited cytotoxicity in both anti-Moloney and anti-H2 systems. Possible mechanisms suggested for the action of heparin included cell surface coating and resultant sequestration from host immune defence mechanisms, or perhaps some kind of permanent induced surface change. Blocking was not felt to arise from anticomplementary effects of heparin.

Taylor, Culling and McDonald[3] showed that heparin in high doses (700 units per 10^5 cells) protected L strain fibroblasts against the damaging effects of specific guinea-pig cytotoxic antisera when mixed with the antiserum. Pretreatment of cells with heparin followed by washing did not protect against later exposure to complement and serum. Fluorescent antibody studies demonstrated that heparin did not prevent the attachment of antibody to cells, and its effect was felt to be anti-complementary. On the basis of this and other work[4] Taylor and Culling postulated interference of aggregation of immune cells around their targets, perhaps secondary to an alteration of cell surface charge or to an anti-complementary effect.

Although previous reports[1-8] seem to indicate that heparin can block certain immunological reactions both *in vivo* and *in vitro*, we have been unable to demonstrate an effect on anti-HL-A cytotoxicity reactions or on HL-A typing of lymphocytes. Heparin, by coating the cell surface or some other mechanism, may have a significant influence on immunological reaction involving mouse cells, but does not seem to have significant effects on human lymphocytes.

Inhibition of Primary Antibody Response by *E. coli* Asparaginase

Astaldi *et al.*[1] reported that *Escherichia coli* L-asparaginase inhibited the blast transformation characteristic of cultures of lymphocytes stimulated by phytohaemagglutinin, a finding which was promptly confirmed by the investigation of McElwain and Hayward[2]. In view of this observation and the known inhibition of protein synthesis[3] by asparaginase, it seemed likely that this anti-tumour agent might also inhibit antibody formation during the primary immune response. To examine this possibility, mice receiving asparaginase were immunized with human erythrocytes (RBC), and their haemagglutinin titres were compared with those of untreated mice.

C3H mice, 8–16 weeks of age, were used in these experiments because older mice of this strain may exhibit rather high agglutinin titres with human RBC (for example, 1:512 with papain treated cells). Mice were bred in this laboratory by litter mate matings. The *E. coli* asparaginase (Merck, Sharpe and Dohme) had a specific activity of 300–400 international units/mg protein. Four groups of mice were used for each experiment: (1) untreated, (2) immunized with RBC, (3) treated with asparaginase only, and (4) treated with asparaginase and immunized with RBC. In a number of experiments asparaginase was administered 5–8 days before giving a single immunizing dose of 10^8 human RBC; asparaginase treatment was then continued for up to an additional 9 days. Serum from the three mice in each group was then pooled for evaluation by serologic titration in saline and with papain treated RBC. All incubations were at 37° C, and RBC were from the same donor that was used for immunization. Saline agglutination was performed by incubating 1 drop of 2 per cent RBC suspension with 1 drop of mouse serum for 30 min. The tubes were then centrifuged and read microscopically for agglutination. Before titering with papain treated cells, 1 mg enzyme (Nutritional Biochemicals, crystalline) was activated for 1 h in 5 ml. 0·9 per cent NaCl containing 12 mg cysteine and 34 mg disodium ethylenediaminetetraacetate. One volume packed cells was incubated with 3 volumes papain solution for 5 min; cells were removed by centrifugation and washed once with 0·9 per cent NaCl. A 2 per cent suspension of the treated RBC was then incubated for 5 min with mouse antiserum, centrifuged, and read microscopically for agglutination.

Table 1. EFFECT OF ASPARAGINASE ON DEVELOPMENT OF C3H MOUSE AGGLUTININS TO HUMAN ERYTHROCYTES

Experiment	Asparaginase* (units/mouse/day)	RBC injection on day†	Serum collected on day†	Agglutinin titre			
				RBC only ‡		RBC + asparaginase	
				Saline	Papain	Saline	Papain
1	5	5	11	32	512	16	64
2	5	8	14	256	2,000	4	32
			17	64	2,000	8	512
3	12·5	6	12	32	1,000	8	64
			15	16	1,000	8	64

* Asparaginase given daily until serum collected.
† Day 1 was the day of the first asparaginase injection.
‡ Control mice not receiving asparaginase.

The protein content of the sera for the experimental groups varied from 58–66 mg/ml., but there was no systematic decrease in asparaginase treated animals. Untreated mice and those receiving asparaginase alone exhibited only low haemagglutinin titres, 1:1–1:4, although occasionally a papain titre of 1:8 was observed. In order to determine that asparaginase was not directly influencing agglutination the enzyme was added to mouse serum in a concentration of 25 units/ml. It had no effect on either saline or papain tests. The RBC donor for experiments 1 and 2 (Table 1) was group B, Rh negative; for experiment 3, group O, Rh positive. The titres which resulted from the RBC immunization were markedly reduced by asparaginase treatment (Table 1). The saline titres were decreased to just above the background level seen in the groups of mice receiving no treatment or asparaginase alone. Papain titres were also significantly reduced. The dose level of asparaginase used in these experiments, namely 200–500 units/kg/day, is at the lower end of the range now being used clinically in the treatment of human acute leukaemia. Although a number of questions concerning immunosuppression by asparaginase remain unanswered, those now using the drug clinically should be aware of this capacity to inhibit antibody formation.

This investigation was supported by a grant from the US Public Health Service.

Positive α_1-Foetoprotein Tests in Pyridoxine Deprived Baboons: Relevance to Liver Carcinoma in Africans

A previous report[1] has described significant histological changes occurring in the livers of baboons that had been deprived of pyridoxine for periods of five months to three years. It was suggested that these changes might be "pre-neoplastic" and that specific dietary deficiencies could be involved—as well as plant or chemical carcinogens or other unknown factors—in the reported high incidence of primary carcinoma of the liver in Africans.

We report here the results of the α_1-foetoprotein (AFP) test on baboons fed a completely balanced artificial diet deprived only of either riboflavin or pyridoxine. The artificial diet, methods of feeding and care of these animals have been fully described previously[2]. The AFP test is highly specific for human and sub-human hepatocellular carcinoma, although there are certain unexplained anomalies[3-6]. The reagents used in our test were supplied by Dr Abelev from the Gamaleya Institute, Moscow. The antiserum was prepared by immunizing rabbits with human α_1-foetoglobulin. Using this rabbit antiserum, we found a "reaction of identity" with the sera of 50 per cent of our pyridoxine deficient baboons, indicating that AFP was present in the serum of these animals. The AFP test was done using both the conventional and triangular technique. All tests were done "blind" and read separately by three different workers; duplicate or triplicate estimations were done on all animals. The test was performed on twenty-five baboons of which ten were pyridoxine deprived, five riboflavin deprived, two pair-fed and eight on their natural diet.

Of the ten pyridoxine deprived animals, five had positive AFP tests. One of these had been on a pyridoxine free diet for three years, although during this period it had several times been given pyridoxine to keep it alive, and when sufficiently recovered, again put back on pyridoxine deficiency. It finally died and was autopsied. The liver had a whitish-grey nodule at the base of the central lobe; the nodule was 3 cm in diameter with a crenated edge and penetrated about 1 cm into the substance of the liver. Similar but smaller nodules were found in other parts of the liver. The AFP test done on serum three weeks before death was positive. The other four baboons with positive AFP tests have been on pyridoxine deficiency for 118 to 440 days and are still alive. Of the five AFP negative pyridoxine deficient baboons, one died after 507 days deprivation and at post mortem was found to have a grossly fatty liver with histological changes similar to those described previously in other pyridoxine deprived animals[1]. The remaining four AFP negative baboons are still alive and have been on pyridoxine deficiency for 146 to 700 days. The testes in all the animals, although juvenile—as in most pyridoxine deprived animals—had no macroscopic or histological abnormalities.

The five riboflavin deprived animals, on which the AFP tests were performed concurrently with the pyridoxine deprived baboons, were all negative and had been on riboflavin deficiency for 152 to 516 days. Although these animals developed gross skin lesions and in some marrow erythroid aplasia, their livers exhibited none of the changes seen in the pyridoxine deprived animals.

The AFP test was also negative in the two pair-fed animals which had been on the synthetic diet for 566 days. The eight naturally fed baboons had been on their normal diet continuously. None of these animals showed any skin, marrow or liver changes: they gained weight normally and were healthy, and their AFP tests were all negative.

We believe this is the first time that a positive α_1-foetoprotein test has been found in sub-human primates made deficient of a single dietary substance—pyridoxine. Pyridoxine is thought to be marginal in the diet of Africans, and if this is so, then its relevance to the high incidence of primary carcinoma of the liver in Africans could be considerable. Our results indicate that pyridoxine, but not riboflavin deprivation, is associated with a positive AFP reaction. Whether the positive reaction precedes, accompanies or succeeds the histological liver damage in the pyridoxine deficient baboons is being investigated. It is not at present known whether treatment with pyridoxine reverses a positive AFP test. What effect upsets in tryptophan metabolism caused by pyridoxine deprivation[7] have on the AFP test is not known at present. Certain metabolites of tryptophan, such as anthranilic and kynurenic acid and 5-hydroxytryptamine, are considered to be associated with carcinogenesis.

There does not seem to be a very close relationship between the duration of the pyridoxine deficiency and a positive AFP test. In some cases, the test was positive after 118 days of deprivation; in others, it was negative after 700 days. The fall in the serum pyridoxine levels, however, was always closely correlated with the duration of the deprivation or the time that had elapsed from the last dose of pyridoxine. These findings may indicate that the relationship between pyridoxine deficiency and a positive AFP test is not a direct one.

There are substantial changes in the serum pyridoxine, vitamin B_{12} and folate levels in the pyridoxine and riboflavin deprived animals, compared with those that were pair fed and those on a natural diet. It is significant that the level of vitamin B_{12} in the serum of members of the pyridoxine deprived group rises eight-fold during the course of the deprivation. Whether these changes in folate and vitamin B_{12} levels have any significance in the development of hepatocellular carcinoma or the positivity of the AFP test is unlikely, but unkown.

Table 1. MEAN SERUM PYRIDOXINE, VITAMIN B_{12} AND FOLATE LEVELS IN GROUPS OF BABOONS

Group	Pyridoxine (ng/ml.)	B_{12} (pg/ml.)	Folate (ng/ml.)
Natural diet	119·0	70·0	7·6
Range	(50–220)	(31—145)	(1·4–22·7)
Pair fed	220·0	119·0	5·0
Range	(127–300)	(80–175	(2·8–8·0)
Riboflavin	52·0	134·0	5·0
Range	(25–107)	(64–146)	(3·3–7·1)
Pyridoxine	9·1	531·0	6·9
Range	(2·2–22)	(64–557)	(3·4–7·6)

Our results indicate that if the α_1-foetoprotein test is indeed specific for hepatocellular carcinoma, then our baboons developed this condition as a result of pyridoxine deprivation. On the other hand, pyridoxine deficiency may produce a positive AFP test *per se*, and whether or not this is associated with histologically acceptable hepatocellular carcinoma is now under investigation. A full report of this work will be published later with histological details of the liver changes.

Failure to detect an Antigen associated with Hepatitis in a Community Epidemic

HEPATITIS associated antigen (HAA) (Australian antigen[1], SH antigen[2]) is often demonstrable in the serum of cases of serum hepatitis. HAA is also reported in infectious hepatitis, although with lesser frequency[3-5]. The latter

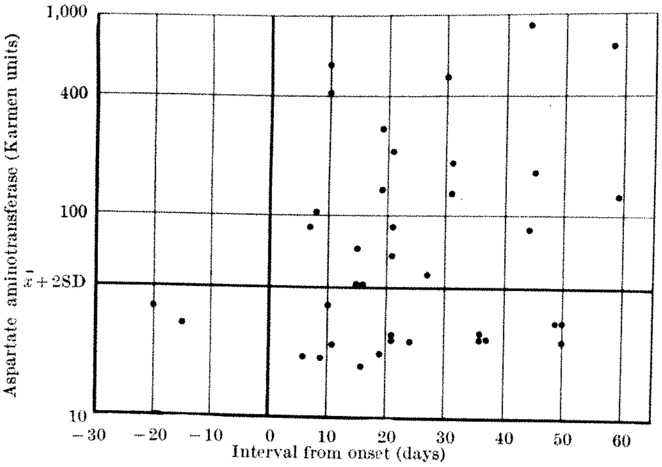

Fig. 1. Scattergraph showing interval in days from onset to collection as well as aminotransferase level of sera from Ely, Nevada. All were negative for hepatitis associated antigen.

observations, however, are in contrast with the finding by Giles and co-workers[6]. None of the children at Willowbrook State School developed HAA in their sera after inoculation with an agent (MS–1) having the characteristics of IH virus. The apparent discrepancy can be resolved only by additional observations using specimens from epidemiologically well characterized cases.

Availability of sera collected in 1958 during a community-wide epidemic of infectious hepatitis prompted the present study. During the 6 month period from October 1957 through March 1958 there were seventy-eight icteric cases of infectious hepatitis reported in White Pine County, Nevada. The epidemic involved the town of Ely (population 6,300), and the smaller communities of Ruth (660) and Spring Valley (330). Most of the cases (68 per cent) were in persons less than 20 years of age. The pattern of the disease in households and the community was consistent with person to person spread; thirty-four of seventy-eight cases had onset of symptoms 2 to 6 weeks after known contact. Immune serum globulin (ISG) was given to members of some households as soon as the index case was recognized, usually in a dose approximating 0·02 ml./kg. Only one of ninety-one persons receiving ISG had clinically recognized hepatitis; there were fourteen icteric cases among eighty contacts not given ISG. After it was recognized that an epidemic of infectious hepatitis was occurring, the National Communicable Disease Center (NCDC) began an intensive study. Serum specimens were collected every 2 weeks from recognized cases, from household contacts, and from families in which illness had not occurred. Assays for L-aspartate : 2-oxoglutarate aminotransferase activity were carried out to determine the extent to which inapparent infections and non-specific illnesses could be diagnosed, especially in household contacts who remained well after ISG was given. The close follow-up of contacts resulted in recognition of anicteric and inapparent infections[7].

The sera collected during the epidemic were retained for evaluation of subsequently developed procedures. The sets of specimens tested in the present study were selected: (1) if one or more sera were collected at a time when HAA was likely to be present, as judged from previous reports[4,9]; or, (2) if there was persistent elevation of aminotransferase. The selected sera were tested for the presence of HAA by the immunodiffusion procedure at both the National Institutes of Health (NIH) and NCDC, and by the complement-fixation test at NIH. The techniques are described elsewhere[5,8].

Fig. 1 records thirty-eight observations of twenty-one patients, thirteen with icteric and eight with anicteric hepatitis. These observations were made from 20 days before to 59 days after onset of symptoms. Eight of the specimens were within 12 days of onset of symptoms; eleven of those taken 21 days or more after onset showed elevated aspartate aminotransferase activities. All specimens were negative for HAA by the immunodiffusion and complement-fixation techniques. Table 1 records five observations of four household contacts with inapparent (asymptomatic) hepatitis. These specimens, all collected while aspartate aminotransferase levels were elevated, were likewise negative for HAA by both techniques.

Table 1. INAPPARENT (ASYMPTOMATIC) INFECTIOUS HEPATITIS, ELY, NEVADA, 1958

Serum No.	Household contact	Bilirubin in urine	Aspartate aminotransferase (Karmen units)	HAA
1	A	+	3,150	—
2	B	+	1,490	—
3	C	−	205	—
4	D	−	154	—
5*	B	−	67*	—

* 14 days after serum No. 2.

These HAA-negative cases meet all the usual requirements for a diagnosis of infectious hepatitis: (1) transmission was predominantly, if not entirely, contact-associated; (2) incubation periods were in the range usually assigned to infectious hepatitis; and (3) a high level of protection was attained with ISG in small doses. It is uncertain whether HAA-positive cases previously reported as infectious hepatitis would also meet these criteria. In sporadic cases, however, differentiation between infectious and serum hepatitis is particularly difficult.

Lack of a history of exposure to a parenteral source of infection is not an adequate basis for designating a case as infectious hepatitis. Obscure exposures to parenteral sources of infection (such as piercing of the ear lobes) may be more important than is usually appreciated. Track-finder's hepatitis[10] could not have been documented if the number of infections acquired by participants in that sport had not been so large. A diagnosis of infectious hepatitis is justified only when there is known contact or the case occurs in an epidemic setting. Patients with probable infectious hepatitis give a history of raw shellfish ingestion or foreign travel more frequently than controls[11], but both events are sufficiently frequent in the general population to limit their value as an indication of the source of infection in any individual.

Our failure to observe HAA positive specimens from patients with typical infectious hepatitis is similar to the experience at Willowbrook State School[6]. The persons studied in the 1958 epidemic in Ely share with those tested by Giles *et al.* the characteristic that the source of their infection could be defined with greater clarity than for patients in the usual hospital setting. There seems little doubt, therefore, that the complete absence of HAA in serum distinguishes at least some groups with infectious hepatitis from patients with serum hepatitis.

Effect of Pregnancy Sera on Isolated Lysosomes

INFLAMMATORY diseases, notably rheumatoid arthritis[1], frequently subside during the last 3 months of pregnancy and recur several weeks after parturition. Evidence implicating lysosomes in the pathogenesis of inflammation[2] suggested that the subsidence of this phenomenon in pregnant human females could be mediated by an effect on these subcellular organelles. We present here evidence that serum from pregnant females stabilizes leucocyte lysosomes. In addition, we have data suggesting that hydrocortisone is not responsible for the stabilizing activity observed.

Table 1. LEUCOCYTE LYSOSOME STABILIZATION BY INDIVIDUAL PREGNANCY SERA*

Control	Per cent of control serum effect †
Matched sera six weeks after parturition	115, 85, 83, 83, 82, 73, 60, 47, 47
Age-matched non-pregnant female sera	79, 75, 67, 64, 60, 50, 47, 47, 45, 23
Matched umbilical cord sera	51, 45, 44, 42, 39, 30, 29

* Pregnancy sera were obtained from patients in their last three months of pregnancy. None was receiving medication. All sera were diluted to a final concentration of 1 : 10 and mixed at 20° C with a suspension of intact rabbit leucocyte granules. The change in absorbance at 520 nm was measured every minute for 3 min following the addition of 'Triton *X*-100'.

† The absorbance change of the lysosome suspension in pregnancy serum is expressed as a percentage of the change noted in the control serum 3 min after the addition of 'Triton'. Shown are the mean values of four–eight determinations for each serum.

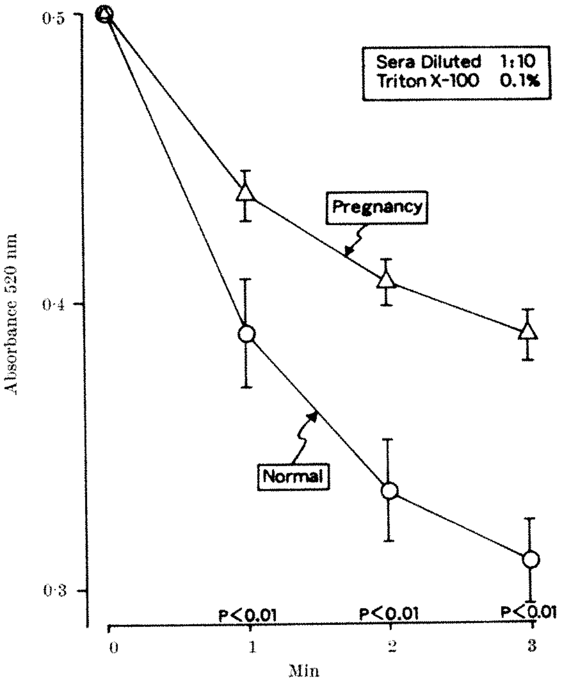

Fig. 1. Effect of pregnancy sera on isolated leucocyte lysosomes. A serum pool composed of sera from six pregnant females in their third trimester (△) is here compared with a serum pool obtained from seven age-matched normal females (○). Sera were mixed with an intact lysosome suspension in 0·3 M sucrose containing 30 units heparin/ml. and absorbance 520 nm change measured following the addition of 'Triton'. Shown are the mean values ± 1 *S.D.* of twelve determinations. Student's *t* test was used for statistical analysis of data.

Lysosomes isolated from glycogen-induced rabbit peritoneal polymorphonuclear leucocytes[3] were suspended in 0·3 M sucrose containing 30 units aqueous heparin/ml. at 20° C. The absorbance at 520 nm of the suspension of intact lysosomes is stable until the addition of 'Triton *X*-100'. This nonionic detergent disrupts organelle membranes releasing their soluble contents, resulting in a rapid decrease in absorbance of the lysosome suspension[4]. A serum pool obtained from six patients in their last 3 months of pregnancy was diluted 1 : 10 in the lysosome suspension before the addition of detergent. The effect of this serum pool on the absorbance of isolated detergent-treated lysosomes was compared with that of a serum pool obtained from seven normal, age-matched females (Fig. 1). It can be seen that the pregnancy serum pool retarded the absorbance change caused by detergent. The absorbance change of the lysosome suspension in pregnancy serum at 3 min is 57 per cent of the change noted in normal serum. This effect was significantly different from normal serum at each time measured. In addition to diminishing the effect of the detergent on absorbance of lysosomes, pregnancy sera also retarded the release of β-glucuronidase from the organelles by the detergent (K. H. H., L. A. F. and R. H. P., in preparation), thus confirming the presence of a lysosome stabilizer in pregnancy serum. The activity of individual sera can be seen in Table 1. The lysosome-stabilizing activities in twenty-six different pregnancy sera are compared individually with either a matched serum from women 6 weeks after parturition, a normal female adult control serum or a matched umbilical cord serum. The rate of absorbance change of all control sera was set as 100 per cent activity. The data indicate not only that varying amounts of lysosome stabilizer are present in most pregnancy sera, but also that this substance does not cross the placental barrier and that it is no longer present 6 weeks after the termination of pregnancy.

The elevated serum concentrations of adrenocorticosteroids present in the latter stages of pregnancy (relative to concentrations usually observed in either non-pregnant females or females 6 weeks after parturition or in umbilical cord samples) was originally thought to account for our observations. Hydrocortisone has been shown to stabilize lysosomal membranes subjected to a variety of stresses[5,6]. We determined the 11-hydroxycorticoid concentrations in the test sera using a fluorimetric method[7]. As expected, pregnancy sera contained high concentrations of cortisol (range = 17–92 μg/ml.), but the stabilizing activity in each serum was not related to its cortisol content. Furthermore, added hydrocortisone did not affect serum stabilizing activity, nor could we demonstrate an effect of this steroid on isolated leucocyte lysosomes stressed by detergent (K. H. H., L. A. F. and R. H. P., in preparation). These findings suggest that hydrocortisone is not responsible for the lysosomal stabilizing property of pregnancy serum. Studies in which corticosteroids have been shown to stabilize membranes have been confined to organelles derived from liver homogenates[5,6]. Evidence has not been presented indicating that cortisol interacts with membranes of the lysosomes from the cells most concerned with acute inflammation, the polymorphonuclear leucocytes.

We conclude that serum obtained from females in their last 3 months of pregnancy contains a factor other than hydrocortisone which stabilizes membranes of leucocyte lysosomes. How this substance regulates lysosomal membrane permeability is not yet known. Nor is the nature of the factor understood although studies in this direction are currently in progress in our laboratory. It appears possible that the development of this substance in the course of pregnancy, capable of interacting with leucocyte organelles to prevent the discharge of their lytic contents, could account for the subsidence of inflammatory disease.

Features of the Synovial Fluid Film in Human Joint Lubrication

THE mechanism of lubrication in human joints depends on the bearing material (articular cartilage), the joint lubricant (synovial fluid) and the operating conditions (sliding or rolling speeds, load and time of load application). Cartilage is a composite of collagen fibre bundles set at various orientations within a ground substance of chondroitin sulphate, and containing a high proportion of watery fluid[1-4]. Its surface, which is very important to the lubrication behaviour, has been found to be rough by engineering standards. The centre line average value has been measured at 30 μinch for healthy cartilage, the roughnesses taking the form of undulations with small ones superimposed on others of larger wavelength[5,6].

Synovial fluid consists of a long-chain high molecular weight polymer, hyaluronic acid, bound to protein, within a dialysate of blood plasma, the resulting fluid being clear, yellow and tacky to the touch[7]. It is well established that the fluid is shear thinning, the sort of viscosities measured being 100 poise at 10^{-2} s shear rate, and 0·1 poise at 10^3 shear rate. A small degree of elasticity has been measured, which is probably very significant in terms of the concentration, molecular weight and "interlinking" of the polymer[8]. The loads and sliding speeds are variable depending on the activity, but typically, in the hip and the knee joints during walking, the loads fluctuate, peaks of three to four times body weight acting during "heel-strike" and "toe-off"[9,10].

Work on the ankle joints of dogs[11] has confirmed the low coefficient of friction, 0·002–0·01, and a mixture of lubrication mechanisms was postulated. We have suggested that a lubricant film between cartilage surfaces is established during joint movements under light load, and maintained under loaded conditions by a squeeze film action. The term "boosted lubrication" by fluid entrapment and enrichment was used to describe this phenomenon[12].

Studies with the scanning electron microscope have given some indication of the appearance of these protecting fluid films. Films were studied in two situations under pure squeezing loads, and under sliding and squeezing combined. In the first, specimens of cartilage covered with synovial fluid were loaded against a glass plate so that the contact loads and times under load represented a range of joint conditions. The situation was frozen by plunge immersion in liquid nitrogen, followed by drying under vacuum at −50° C. Contact loads used were from 3–15 kg/cm², and times from 2–90 s. In the second case, cartilage specimens sliding on glass were immersed within 1 s into liquid chlorodifluoromethane ('Arcton 22', ICI) close to its freezing temperature of 160°, to be followed again by vacuum drying.

The surfaces of the specimens were coated with about 500 Å of silver and examined in the stereoscan, scanning electron microscope.

With comparable conditions of load and time under load, the deposits observed on the cartilage surfaces pre-

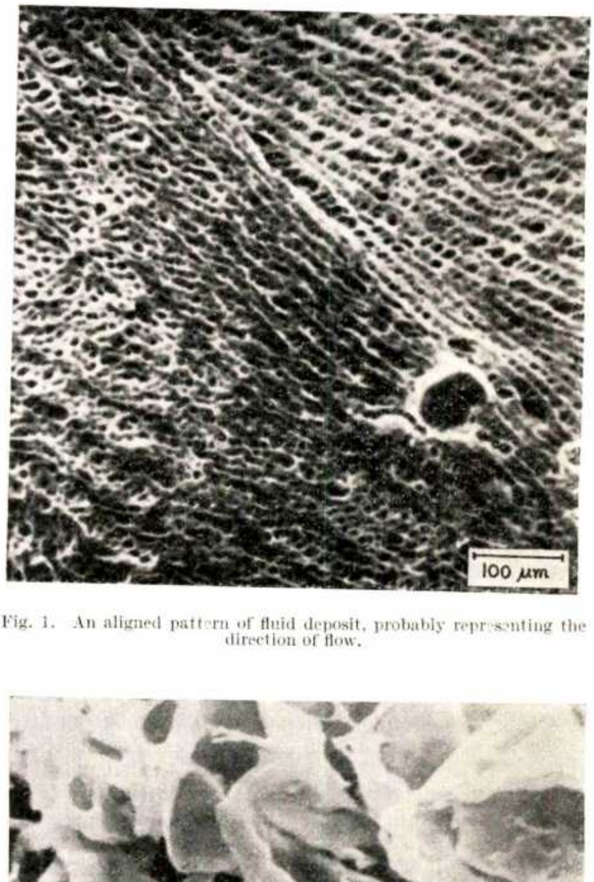

Fig. 1. An aligned pattern of fluid deposit, probably representing the direction of flow.

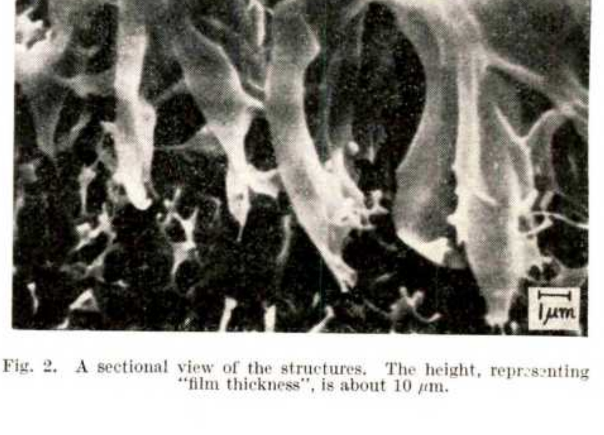

Fig. 2. A sectional view of the structures. The height, representing "film thickness", is about 10 μm.

pared by both methods displayed similar characteristics. The thickness of the deposit, which would represent roughly the film thickness betweeen the cartilage and glass, ranged from a maximum of about 10 μm to a minimum of about 0·25 μm, the former resulting, for instance, from a contact load of 3 kg/cm² acting for 2 s, and the latter for 15 kg/cm² acting for 5 s.

Fig. 1 shows that as the fluid was just being squeezed from between the surfaces, the flow was in preferred directions leaving a strongly orientated pattern of deposit. A sectional view at high magnification showed that there was an arcade-like structure formation (Fig. 2), the height of about 400 μinch representing film thickness. After longer times under load, the structures were collapsed (Fig. 3), until the limiting condition was reached of a complete skin over the surface (Fig. 4). A number of studies showed that the skins could be of double or treble thickness, particularly where there were trapped pools of fluid in the undulations on the cartilage. It seemed that the polymer had tended to be separated from the watery dialysate, the water having flowed out sideways and perhaps into the pores of the cartilage at low film thickness. This latter mechanism has been shown to be feasible by Maroudas[13].

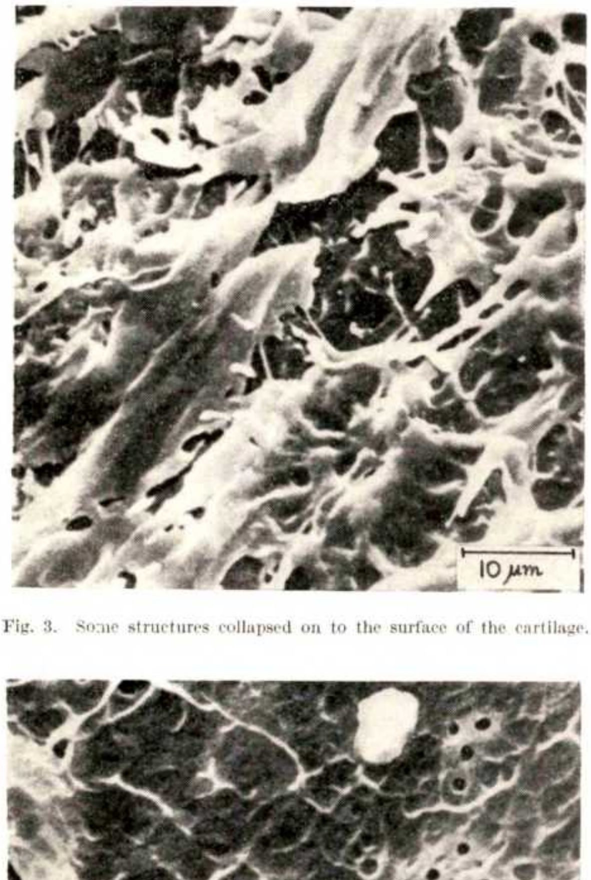

Fig. 3. Some structures collapsed on to the surface of the cartilage.

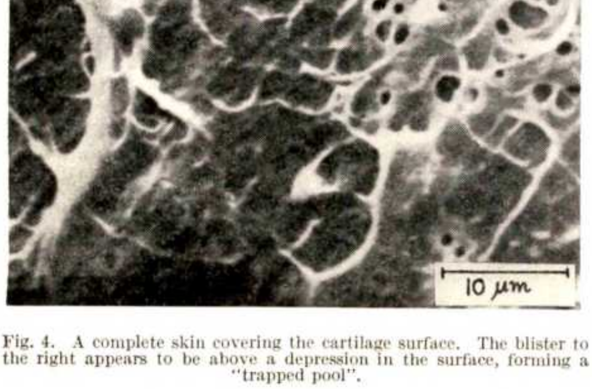

Fig. 4. A complete skin covering the cartilage surface. The blister to the right appears to be above a depression in the surface, forming a "trapped pool".

It is suggested that in activities such as walking the load-time combination is such that hip and knee joints will operate in a fairly thick film condition many times greater than the minimum of 0·25 μm, the film being recharged on swings of the joint under light load. Even when the thin film condition is reached, however, this will be an efficient protection mechanism for the cartilage surfaces. It will be very resistant to further thinning because of the very small flow rate of the thin layers of watery dialysate which would probably exist between the skins; but also, these thin watery layers would offer little resistance to sliding, accounting for the very low coefficient of friction.

Substitute polymers in solution which may possibly equal the remarkable lubricating properties of synovial fluid are currently being studied.

Scanning Electron Microscope Studies of Human Trabecular Bone

We wish to draw attention to the advantages of the scanning electron microscope in investigating the architecture of trabecular bone. This tissue, which contains about 25 per cent by weight of bone and 75 per cent of marrow[1,2], is important in the dosimetry of bone-seeking radionuclides. We have accordingly begun our work by using

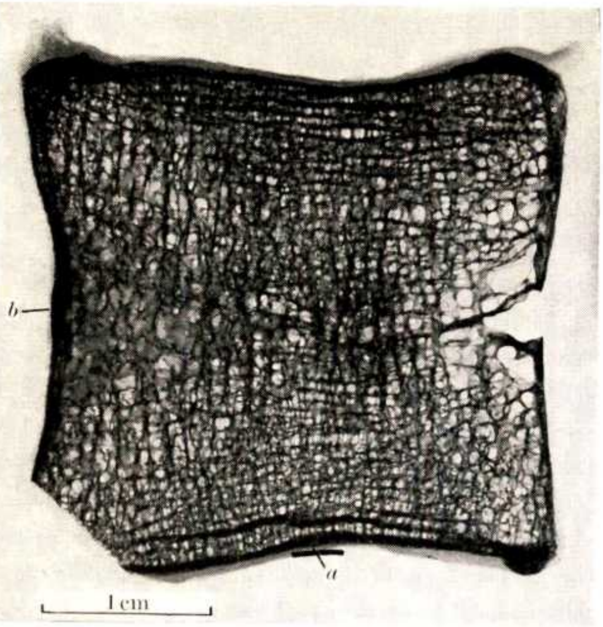

Fig. 1. Print of contact radiograph of sagittal section of vertebral body (one corner removed during preparation). The posterior vascular foramen is to the right.

the Stereoscan microscope at its lowest powers of magnification (×10 to ×100) to elucidate the general arrangement of the bony elements and to make estimates of their volume and surface area.

Two sections 3–5 mm thick were sawn, one a complete sagittal section and the other at right angles to it, passing through the foot of the neural arch. The surfaces were polished under liquid nitrogen so that the hard-frozen marrow protected the bone from damage or distortion. The marrow was washed out at room temperature with a water jet. The sections were then dried and treated with a thin coat of Duron[3] antistatic agent.

Fig. 1 is an enlarged print of a contact radiograph of the sagittal section. The structure inside the vertebral body varies considerably and, notably, there are dark lines indicating concentrations of bone at right angles to the section, especially near the intervertebral disks.

The Stereoscan photographs in Fig. 2*a* and *b* show the areas adjacent to the opaque markers in Fig. 1. The surface electron micrographs give almost no indication of underlying chemical composition; for example, uncalcified tissue can be identified only by its morphological appearance.

In Fig. 2*a* the cortical wall is seen to contain narrow channels, presumably vascular channels. A second region of thicker bone, with channels, can be correlated with the most conspicuous dark line in Fig. 1. There are many short sturdy rods, about 750–1,000 µm long and from about 100–200 µm thick at their centres. There are also a number of small laminae which appear to be about 75–100 µm thick. There is nothing which could be described as an enclosed marrow space, but rather a marrow continuum intersected by a coherent framework of bone.

Fig. 2*b* is a complete contrast. It is composed exclusively of thin curved laminae about 75–100 µm thick, enclosing large interconnecting marrow spaces. In many other regions of the vertebral body the rod-like and plate-like structures exist in close proximity.

Measurements of the area of the polished bone surface and of the boundary between bone and marrow were made in twelve small regions, six from each section, excluding cortical bone. The relative area, by Delesse's theorem[4,5], is numerically equal to the relative volume of bone. The relative weight can thus be calculated. Further, from the perimeter, with certain assumptions about the isotropy of the structure[5], the area of the surface separating bone and marrow can be deduced. Table 1 gives details.

Table 1. SUMMARY OF MEASUREMENTS

Relative area of polished bone surface	$0{\cdot}13_5$	cm^2/cm^2 surface area of section
(Near intervertebral disks, approx.	0·18	cm^2/cm^2 surface area of section)
Calculated fraction by weight of bone in trabecular bone tissue	0·23	
(Near intervertebral disks, approx.	0·30)	
Perimeter of polished bone surface	22	cm/cm^2 surface area of section
Calculated area on interface between bone and marrow	28	cm^2/cm^3 trabecular bone tissue

(Specific gravity of bone, 2 g cm^{-3}; of marrow, 1 g cm^{-3})

In spite of the very different appearance of the structure at different parts of the vertebral body, the measured areas and perimeters are fairly close to the average except very near the intervertebral disks. The exact definition of the polished surface means that systematic errors should not be large.

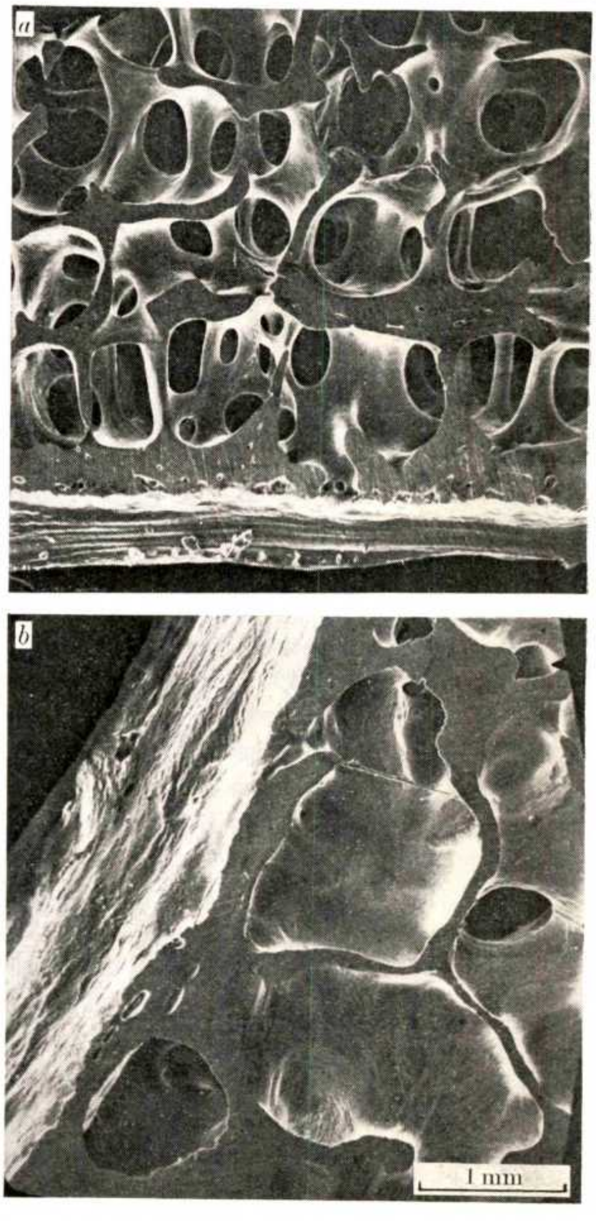

Fig. 2. Stereoscan pictures of regions *a* and *b*, opposite the positions of the markers in Fig. 1. The upper surface of the bone has been polished and the marrow washed out. There are remnants of soft tissue adhering to the outer surface of the bony cortex. Same scale for *a* and *b*.

Our relative area measurements agree quite well with those of Robertson and Godwin[6], who found 11·6 per cent of bone area. They also lead to a relative weight which agrees with our own chemical analyses. Dunnill *et al.*[7] found 25·3 ± 2·6 per cent for the percentage volume of bone, and 30·0 ± 6·1 cm^2 per ml. for the surface area in lumbar vertebral bodies from males in the 20–29 age group. They included cortical bone, which would have a much greater effect on the volume ratio than on the surface area.

Lloyd *et al.*[8] have published automatic measurements of bone perimeters in micrographs of bone sections 100 μm thick. For a lumbar vertebra they find 90 cm/cm^2 of bone surface. In our sections the corresponding figure (perimeter/relative area of bone) is 22/0·135 = 165 cm/cm^2 polished bone surface.

We hope to publish a more detailed account of this work elsewhere. We thank Dr G. M. Ardran and Mr H. E. Crooks for taking the X-radiograph and also Dr Ardran for obtaining the bone sample.

Cyclical "On Demand" Oral Intake by Adults

RESEARCH into cyclical events of sleep[1] has dealt notably with the appearance every 90 min of rapid eye movement (REM, paradoxical or dreaming) sleep. REM sleep was first seen with an hourly periodicity in small infants. If the infant was feeding "on demand" the demands were related to the hourly cycle[2]. The oral activity (eating, drinking, smoking) of ten unsuspecting adults[3], mostly alone, during periods of 6 h or more, has also revealed a cyclical pattern with a periodicity of just over one and a half hours. Different weightings were given to different oral activities in accordance with psychoanalytic tenets: milk, for example, had extra weight because of its "basic" oral quality. Even without the weighting, however, a cyclical pattern was evident. Seven schizophrenic patients showed similar patterns during one 6 h session each[4].

In an attempt at confirmation J. M. and I. O. observed eight young adults for from one to ten sessions each; there were twenty-seven sessions in all. As a preliminary each subject had electroencephalographic electrodes and a small box fixed to the head and was shown biotelemetry equipment. The subjects drew their own conclusions: in fact none realized the purpose of the experiment. It was agreed in advance that each session should be of 6 h duration; they could occupy it as they chose and would not be interfered with.

The subjects were observed alone through a one-way screen for 6 h (in some cases boredom reduced the time to 5 h 45 min) in a comfortable room containing a coffee table with coffee powder, milk, apples, saccharin, still and carbonated fruit drinks, chocolate, water and utensils. To reduce possible digestive or sugar-metabolism factors, only low-calorie fruit drinks and Cadbury's diabetic chocolate were provided. No subject recognized the special nature of these foods. They occupied their time in reading, studying, napping and so on.

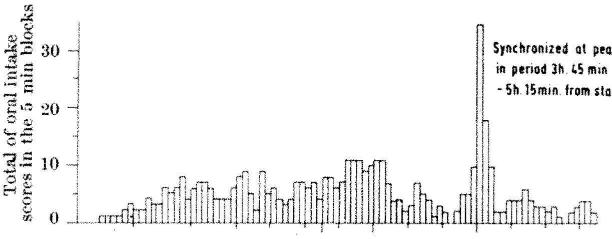

Fig. 1. Distribution of oral intake scores when peak intakes were synchronized for the period 3 h 45 min to 5 h 15 min from the start. The figure shows the two groups of eight 5 min blocks, around the 90 min and the 135 min marks, which were used in the analysis of results.

The 6 h period was divided into 5 min blocks or intervals on a scoring sheet and the observer scored each oral act, namely, each bite of chocolate, each sip of drink, each puff of smoke, and every instance where pencil, pen or fingers went on or into the mouth or nose.

The great amount of contact around the snout area was surprising and we can only suppose that it passes unremarked in normal life because of its ubiquity. Owing to its continual presence we have not used it in our analysis of data. Nor have we used the smoking scores, for it proved impossible to be sure whether a tobacco pipe was still alight and when a puff of smoke had actually been drawn. Our eventual scoring was confined to feeding and drinking.

In analysing the data each 5 min block was given a score based on the number of different forms of eating or drinking in the 5 min. In this first procedure the number of individual sips of drink or bites of apple was not taken into account, for there seemed no grounds for considering eight sips of coffee to be worth more than one bite of chocolate. Thus a 5 min block containing six bites of apple only scored 1, but a 5 min block with two bites of chocolate and three sips of lemon drink scored 2.

To synchronize the peaks of oral activity in the different sessions, we adopted a procedure resembling that of Friedman and Fisher[3]. When they entered the experimental room, the subjects tended in the first minutes to sample the food available. Our synchronization procedures, however, have in all cases avoided both the first and last 30 min of the sessions. In the first place the peak of oral activity in the 90 min around the 4·5 h mark in each session was determined, namely between 3 h 45 min and 5 h 15 min. As Friedman and Fisher found, there was little difficulty in selecting a peak. When there were two equal scores the number of sips of drink or bites of food served as a guide; when two adjacent 5 min blocks were identical the first was arbitrarily taken as the peak. The peak score was noted at a central zero mark on a graph and the scores in the 5 min blocks on either side throughout the whole session were marked at appropriate distances. This was done for all records and the scores accumulated (Fig. 1). In two cases there had been no oral intake in the key period so that these sessions had to be omitted. Consequently the accumulated scores are based on twenty-five records.

Similarly the peak 5 min block of oral activity between 30 min and 2 h from the start of every session was deter-

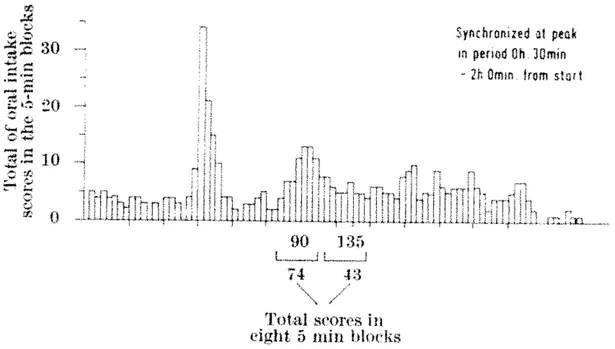

Fig. 2. Distribution of oral intake scores when peak intakes were synchronized for the period 0 h 30 min to 2 h from the start. The two groups of eight 5 min blocks used in the analysis are again shown.

mined. Again two records had to be omitted because they showed no oral intake in the key period. The other twenty-five were synchronized and the scores for the sessions again accumulated (Fig. 2).

In selecting peaks we were *ipso facto* selecting "lows" and, because the peaks were evenly spread over the 90 min periods from which they were selected, we should expect "lows" to extend for one and a half hours on either side of the synchronized peaks in Figs. 1 and 2, with a rise therefore expected at 90 min before and after the synchronization point. If oral activity were random the curve should then level off until diminishing data caused a fall. In particular, in Fig. 1 a "low" should be present between the synchronization peak and the 90 min mark before that peak, and there should be no "low" around the 135 min mark before the synchronization peak. If, on the other hand, a 90 min cycle of oral activity were present, then a "high" would be hypothesized around the 90 min mark and a "low" around the 135 min mark. In this connexion the four 5 min blocks on each side of that 90 min mark which lies before the synchronization peak in Fig. 1 were found to contain the eight scores shown in Table 1. The eight 5 min blocks are separated in Fig. 1 by a single 5 min block from the eight blocks grouped on either side of the 135 min mark. These last eight scores are also shown in Table 1.

Table 1. THE SCORES IN THE GROUPS OF EIGHT 5 MIN BLOCKS AROUND EACH HYPOTHESIZED "HIGH" AND "LOW"

	Hypothesized "highs"	Hypothesized "lows"
Fig. 1.	11, 11, 9, 10, 11, 11, 7, 4 (total 74)	7, 6, 7, 4, 8, 8, 6, 7 (total 53)
Fig. 2.	4, 7, 7, 11, 13, 13, 11, 8 (total 74)	6, 5, 5, 7, 5, 5, 4, 6 (total 43)

Similarly for Fig. 2, if oral activity were random there should be no "low" around the 135 min mark after the synchronization peak, but if a 90 min cycle were present one would hypothesize a "high" around the 90 min mark after the synchronization peak and a "low" around the 135 min mark. The scores for the eight 5 min blocks around each of these two marks are given in Table 1.

If we examine the possibility that the sixteen scores of "high" 5 min blocks in Table 1 could be drawn from the same distribution as the sixteen scores of "low" 5 min blocks, $t = 3.64$ ($P < 0.001$).

The phenomenon of adult, oral intake occurring cyclically has thus been observed in the conditions of our own study, as in the conditions of Friedman and Fisher's study. To determine variations in periodicity within and between individual subjects the scores were later examined by an independent mathematician (H. L.) and subjected to periodogram analysis[5].

An approximate period of n units (1 unit $= 5$ min) was adopted and the observations for each individual set up in arrays of n columns. The correlation ratio (the ratio of the *S.D.* of the weighted means of the vertical arrays to the *S.D.* of all the observations in the distribution) was calculated for period n in each trial for each individual. This procedure was carried out for various values of n and graphs of the correlation ratio against the period n were plotted. From these graphs, the value of n with the maximum correlation ratio was the required number of units in the period. For example, a maximum correlation ratio of 1·23 for $n = 19$ gives a period of 95 min. The periodicity of oral activity for each trial, to the nearest 5 min, is shown in Table 2 and it can be seen that values cluster around 90 min.

Table 2. PERIODICITY OF ORAL ACTIVITY

Subject	Activity in the 27 sessions (min)	Hour of commencement of session
S	105, 90, 95, 95, 95, 85, 85, 90, 85, 90	1415, 1320, 1355, 1125, 1330, 1205, 1520, 1415, 1245, 1025
M	100, 90	1515, 0930
R	95, 95	1340, 1210
C	80, 80, 90	1415, 1410, 1035
P	105	1415
N	90, 100	1355, 1355
L	80, 85, 90	1415, 1400, 1320
W	80, 90, 95, 80	1110, 1045, 1445, 1325

The rate of rise to the peak value of the correlation ratio was found from (1) the correlation ratios for the two periods immediately preceding the period containing the maximum correlation ratios and (2) the maximum correlation ratio. The best straight line through these points was found by least squares. The slope of this line gave an indication of the speed of attaining the maximum correlation ratio. These gradients are shown in Table 3.

Table 3. RATE OF RISE TO MAXIMUM CORRELATION RATIO FOR THE TWENTY-SEVEN SESSIONS

N	0·06, 0·02
L	0·28, 0·05, 0·14
W	0·01, 0·05, 0·05, 0·14

Our subjects began their sessions at times varying from 0930 to 1520 h (Table 2). We can see nothing in our data that would allow of an explanation of the findings in terms of any learned periodicity of intake. The conventional British sequence of breakfast, morning coffee, lunch, afternoon tea and evening meal does not conform to a 90 min pattern.

It seems to us probable that a one and a half hour cycle of oral events in waking life would be related in the adult, as in the infant, to the cycle of events that follow a similar periodicity within sleep. The periods of cyclically recurring REM sleep are accompanied by dreaming, penile erections, irregularity of the heart and breathing, and other changes characteristic of behaviour governed more by emotion than by reason. A cyclical pattern of oral intake, which we have demonstrated, and the continual touching of the nose and mouth, on which we have remarked, would serve to illustrate how covert urges may shape our waking lives.

Effects of 6-Hydroxydopamine on CNS Catecholamines, Spontaneous Motor Activity and Amphetamine Induced Hyperactivity in Rats

THE compound 6-hydroxydopamine (6-OHDA) produces a long-lasting depletion of brain noradrenaline (NA) and dopamine (DA) when injected into the lateral ventricle of the rat brain[1]. This treatment also results in a reduction in the activities of the catecholamine biosynthetic enzymes, tyrosine hydroxylase and DOPA decarboxylase, in the hypothalamus and corpus striatum. In addition there is a marked reduction in the rate of uptake of ^{3}H-NA into tissue slices from these regions[1]. These findings are consistent with the evidence from morphological studies[2,3] which suggest that the compound causes an acute degeneration of adrenergic nerve terminals in the sympathetic nervous system when administered systemically. The effects of 6-OHDA in the CNS are restricted to NA and DA containing neurones, and there is no recovery for periods of up to 142 days after treatment[1]. The doses of 6-OHDA injected into the brain are not sufficiently large to have any effects on the peripheral sympathetic nervous system[2].

In a preliminary study of the effects of 6-OHDA on animal behaviour, amphetamine-induced hyperactivity was investigated before and after drug treatment. Male albino Wistar rats (weighing initially 150 g) were acclimatized to photocell activity boxes on 4–6 successive days, until a stable baseline of spontaneous motor activity was attained. This was accompanied by a reduction in defaecation to a stable level while in the box. (+)-Amphetamine in saline was injected intraperitoneally (0·5 and 1·5 mg/kg; expressed as free base) and the rats were placed in a holding cage for 55 min. They were then transferred to the activity boxes and scored individually for a 10 min test period, previous experiments having established that the peak amphetamine effect occurred at this time. Individual cumulative records showed that the rate of activity during the sampling period was constant, after an initial burst in the first minute. Precautions were taken to exclude extraneous stimuli from the boxes, and the recordings were made between 1100 h and 1500 h to reduce variations arising from diurnal changes in motor activity. Control motor activity was measured 55 min after the injection of a saline placebo. The investigation of high doses of (+)-amphetamine (>3·0 mg/kg) was discontinued, because the stereotyped behaviour predominating at these doses interfered with the measurement of motor activity.

Rats were anaesthetized with ether, and 6-OHDA, dissolved in 20 µl. of cooled Merlis solution, was injected into the lateral ventricle of the brain[1]. The solution contained ascorbic acid (1·0 mg/ml.) to retard autooxidation of the drug. One group of sixteen animals received 100 µg of 6-OHDA (free base) per animal; a second group received two doses of 250 µg per animal (with an interval of two days between doses). During the second week after 6-OHDA treatment, testing was resumed, and the responses to the same doses of amphetamine and to a saline placebo were again measured.

Animals were then killed by stunning and decapitation, and the brains were rapidly removed and assayed for NA and DA. The results obtained from rats treated with 6-OHDA were expressed as percentages of control values for animals treated with the vehicle solution alone (Table 1). The results were in agreement with those previously described for rats treated with these doses of 6-OHDA (ref. 1).

Rats treated with 100 µg of 6-OHDA did not exhibit a significant change in control motor activity (before 6-OHDA = 156 ± 12; after 6-OHDA = 149 ± 17 counts per 10 min per rat). Burkard, Jalfre and Blum[4] also found no change in spontaneous motor activity after administration of 250 µg of 6-OHDA in rats. In animals treated with 2 × 250 µg, however, control motor activity was significantly reduced (before 6-OHDA = 181 ± 14; after 6-OHDA = 120 ± 12, $P<0{\cdot}01$) (Fig. 1).

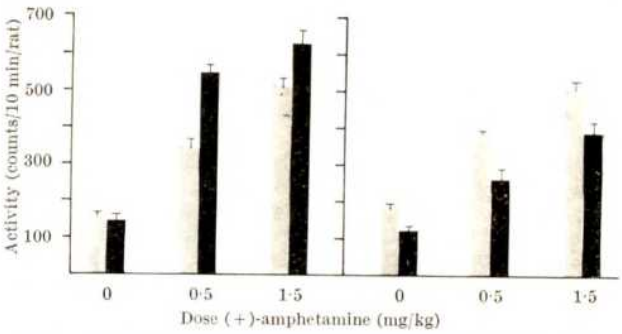

Fig. 1. The effects of (+)-amphetamine on motor activity in rats, before (stippled columns) and after treatment (black columns) with 6-OHDA. Two groups of sixteen animals received 100 µg (on the left) and 2 × 250 µg (on the right) of 6-OHDA respectively. Values are means ± *S.E.*

The effects of 6-OHDA treatment on (+)-amphetamine induced hyperactivity are summarized in Fig. 1 and Table 2. The time course of the response to amphetamine was found to be unaltered. The increases in motor activity are expressed as the scores obtained with amphetamine minus the mean control scores (Table 2). These increments are also expressed as percentages of the respective control motor activities (Table 2). After 100 µg of 6-OHDA there was a significant enhancement of the amphetamine effect at both 0·5 and 1·5 mg/kg. Because the control motor activity was unchanged, the percentage effect was also significantly increased. After doses of 2 × 250 µg of 6-OHDA, the amphetamine effect was not significantly different from that measured in the same animals before treatment.

These results show that amphetamine stimulates motor activity in the rat even after the substantial depletion of brain catecholamines induced by 6-OHDA. It has been suggested that catecholamines in the brain play an important part in the regulation of motor activity and in the stimulation of motor activity by (+)-amphetamine[5–7]. Our results suggest, however, that there is no simple relationship between brain catecholamine levels and the magnitude of the amphetamine response. For example, the amphetamine response was not significantly reduced after 2 × 250 µg of 6-OHDA, although brain NA and DA were reduced by 75–80 per cent. Spontaneous motor activity, however, was reduced in these animals. After 100 µg of 6-OHDA, spontaneous motor activity was not affected, but the amphetamine response was significantly enhanced. This dose caused a differential depletion of the two catecholamines, NA being more severely depleted than DA (Table 1). The enhanced

Table 1. EFFECTS OF 6-OHDA ON BRAIN NA AND DA

Dose 6-OHDA (µg/rat)	NA	DA
100	38·5 ± 3·2 per cent	65·0 ± 6·4 per cent
500 (2 × 250)	21·0 ± 3·9 per cent	26·5 ± 4·3 per cent
Control values (µg/g brain)	0·298 ± 0·009	0·584 ± 0·040

NA and DA contents of experimental animals are expressed as percentage of control values.

Values are means ± *S.E.* (twelve–sixteen animals) and are not corrected for losses during the isolation procedure.

Table 2. ACTIVITY MEASUREMENTS

Dose 6-OHDA (µg/rat)	Dose (+)-amphetamine (mg/kg)	Increment in activity (counts/10 min/rat)		Increment in activity as per cent of control activity	
		Pre 6-OHDA	Post 6-OHDA	Pre 6-OHDA	Post 6-OHDA
100	0·5	174 ± 24	396 ± 20†	115 ± 16·5	257 ± 20·4†
	1·5	358 ± 22	547 ± 31†	229 ± 13·8	367 ± 29·9†
500	0·5	204 ± 13	148 ± 27*	113 ± 7·4	124 ± 21·8
(2 × 250)	1·5	339 ± 23	272 ± 28*	187 ± 15·4	221 ± 24·0

Measurements were made 55 min after (+)-amphetamine, after subtraction of the respective control values for saline injected rats. Values given are means ± *S.E.* for sixteen animals.

* $0{\cdot}1 > P > 0{\cdot}05$. † $P < 0{\cdot}001$ (with respect to pre 6-OHDA value; *t* test).

amphetamine response may be related to this change in the ratio of the two catecholamines. It has been suggested that the dopaminergic system of the neostriatum may be directly involved in the hyperactivity produced by (+)-amphetamine[8] and that NA may have inhibitory effects on activity[9,10].

Animals with the severe depletion of brain NA and DA induced by 2 × 250 µg of 6-OHDA were difficult to distinguish from normal animals, when examined 7 or more days after treatment. During the first few hours after receiving the drug, the animals assumed a posture with hunched back and raised fur, resembling reserpine treated rats. Motor activity and rearing were much reduced for the first few days, and the animals were extremely sensitive to tactile stimuli, preferring to remain isolated from other rats in the home cage during this period. They were more irritable on handling than normal rats, and this persisted after the general appearance had returned to normal (one week after injection). Food intake and water intake decreased initially, but recovered within 72 h after drug treatment. It is possible that during recovery some functions of the brain catecholamines are taken over by residual catecholamine neurones or by other neural systems. The catecholamines remaining in the brain after 2 × 250 µg of 6-OHDA were depleted by treatment with reserpine (5 mg/kg, intraperitoneally), which produced a sedation in animals whose appearance had returned to normal.

Animals treated with 100 µg of 6-OHDA showed few obvious changes in behaviour, even during the first week after treatment. Mock fighting behaviour was observed in some of these animals after the administration of 1·5 mg/kg (+)-amphetamine; this resembled the behaviour reported in rats treated with L-DOPA and a peripheral DOPA decarboxylase inhibitor[11]. This "bizarre social behaviour" was not observed in normal animals or in those treated with 2 × 250 µg of 6-OHDA, and may also be related to the change in the ratio of NA and DA in the brain.

By using 6-OHDA it is possible to produce selective chemical lesions of catecholamine-containing neurones in the CNS, and such lesions seem to be virtually permanent. Furthermore, by adjusting the dose of 6-OHDA, a selective destruction of noradrenergic rather than dopaminergic nerve terminals may be achieved. Although brain catecholamines have been implicated in a wide variety of important behavioural and physiological functions, gross depletions of these amines by 6-OHDA do not seem to produce correspondingly large changes in behaviour.

We thank Drs H. Thoenen and J. Tranzer of F. Hoffmann La Roche, Basle, Switzerland, for generous supplies of 6-hydroxydopamine. K. D. E. is supported by a scholarship from the Medical Research Council.

Aberrant mRNA in Parkinsonism: Support for Hypothesis from Studies with Chloramphenicol

THE observations that the normally high concentration of dopamine in the substantia nigra is reduced in Parkinsonism[1], that reserpine, which depletes catecholamines, can produce a Parkinsonian syndrome[2] and that both anticholinergic drugs and L-dopa partially relieve the symptoms of the disease[3,4], have led to the implication of an imbalance between dopaminergic and cholinergic activity in Parkinsonism. Our recent results, however, support previous reports that, apart from a neurotransmitter deficiency, a dysfunction of protein synthesis might be involved. According to this hypothesis, an unknown agent interferes with the normal function of the glial genome. It stimulates the synthesis of new messenger RNA (mRNA) which specifies proteins for growth and division. The normal inverse metabolic coupling between neurone and glia is disturbed during proliferation, and as a result similar changes to those in the proliferating glia may occur in the neurone, leading to its biochemical and functional de-differentiation. The neurone may no longer be capable of synthesizing certain functional proteins, including those needed for neurotransmitter synthesis, transport and storage. As a result, though not degenerate, it would fail to act as a signalling device. Our data in support of this hypothesis are (*a*) that reserpine, which induces a Parkinsonism-like syndrome in man[2], induces increased synthesis of DNA, RNA and proteins in animals, and intense glial proliferation[5]; (*b*) that an increase in RNA, inversely related to melanin content, occurs in the nigral neurones of Parkinsonian patients who died during the early stages of the disease (M. I., submitted for publication); (*c*) that an abnormal electrophoretic pattern of blood cell proteins was found in Parkinsonian patients (H. Pataryas and C. N. S., manuscript in preparation).

Previously it has been found that gliosis is constantly found in the substantia nigra affected by the disease, that demelanization of nigral neurone is commonly seen even when no loss of neurones is observed (MacAlpine, cited in ref. 6), and that demelanization of nigral cells occurs in humans when reserpine and phenothiazine derivatives are used therapeutically[7]. Moreover, in biopsy material of globus pallidus, a significant increase in aberrant mRNA content in the glia was found early in the development of the disease and a similar increase in RNA in the neurones was evident later[8]. Other studies have demonstrated that demelanization of cultured pigmented retinal epithelium cells occurs as a result of a dramatic increase in the rate of synthesis of new mRNA for the production of growth proteins for the rapidly dividing cells[9]. Further, it has been shown that cultured heart cells grown as monolayers dedifferentiate and stop beating[10]. Finally, cell hybridization experiments indicate that in hybrids of melanin producing cells with non-pigmented cells the non-pigmented cell genome may repress the expression of tyrosinase genes[11] and "such dedifferentiated pigment cells covertly maintain their potentiality to express the original melanotic function and can be made to re-express it"[9].

To test our hypothesis we first studied the effects of certain inhibitors of protein synthesis on patients with Parkinsonism, because some of these inhibitors, in addition to blocking proliferation, may also restore the "differentiated" state of the cell[9,10]. Chloramphenicol was chosen because it specifically inhibits protein synthesis resulting from the rapid turnover of mRNA in proliferating cells[12] and does not affect protein synthesis of differentiated mammalian cells[13], including neurones[14].

Patients included in the study were clinically diagnosed as suffering from Parkinson's disease; they understood that the treatment involved the risk of side effects, for the early detection of which frequent blood tests would be required. Age, sex, severity and course of the disease, possible aetiological factors and prevalence of particular neurological signs were random variables. Twenty-four subjects were selected; three were excluded on account of slight side effects, and of the remainder, eighteen Parkinson patients received chloramphenicol and three (controls) did not. The severity of major neurological signs such as rigidity, tremor and dyskinesia was noted before administering the drug. Speech impairment, abnormalities of posture and gait, extent of salivation, lachrymation and dysphagia were recorded. Standard functional tests included the time required for, and manner of, rising from a chair and a bed, handwriting, shuffling, dressing, undressing and walking a fixed distance (in the latter case the number of steps was also noted). Ergographic, EMG and H-reflex tracings were obtained. Haematological tests were performed three times a week. Blood pressure was measured regularly and ECGs and EEGs were taken.

Each patient was assigned to one of five groups of examiners, and was also periodically inspected by other examiners. One examiner knew all the patients and made his own evaluation, keeping independent records. Cinematographic records of eight patients were also made before, during and after the treatment. Patients who, on admission, had been receiving antiacetylcholine drugs continued to do so; others received only chloramphenicol. The dose of chloramphenicol was 1·5–2 g administered orally each day throughout the period of treatment (3–6 weeks). Patients knew that they were to be given a multiple stage treatment but were not told that this included innocuous pills before and/or after administration of chloramphenicol. Four patients received placebos as well for about a week before and a week after the administration of chloramphenicol.

The results were assessed semi-quantitatively. It was noted that a clinical change occurred in nearly all patients on active chloramphenicol treatment. The degree of response ranged from no improvement (one case) to complete restoration to normal (one case). The delay between administration of the drug and the appearance of the first signs of improvement ranged from 4 to 17 days, duration of delay apparently being unrelated to degree of clinical response. One patient, for example, experienced both the longest delay before observable improvement and the greatest benefit: all symptoms disappeared in four weeks. Improvement first appeared as a decrease in intensity in one or more of the neurological signs and/or as an increase in general mobility. Often the patient reported the change spontaneously. Dyskinesia and rigidity seemed to be affected earlier than tremors. In several cases, tremor disappeared completely, but considerable rigidity and dyskinesia persisted: this indicates that no correlation exists between the sequence and degree of any particular sign. Maximal improvement was reached 1·5–4 weeks after the onset of change. It persisted for a variable time (1–4 weeks after the termination of therapy). The decline followed a sequence which was the reverse of that noted in the course of improvement: tremor, the last sign affected by the drug, was the first to re-emerge upon the cessation of treatment. Some cases reverted to pretreatment level in less than two weeks; others still showed some benefit three months later. No clear relationship was noted between degree and duration of improvement following drug administration.

The results demonstrate that chloramphenicol, a specific inhibitor of protein synthesis in rapidly proliferating cells, modifies the chief symptoms of Parkinsonism. Viewed in conjunction with the concept of a close neurone–glia metabolic coupling[15], this supports the hypothesis that a protein synthesis abnormality in the nigral neurone, initiated by aberrant metabolism of its glia, is involved in the pathogenesis of this disease. The interval between the beginning of the therapy and the occurrence of observable clinical effects is consistent with the time required for the neurones to switch from the "dedifferentiated" to the "differentiated" state. The variability of clinical response is explicable on the assumption that the degree of clinical change depends on the percentage of "dedifferentiated" neurones which can be induced to revert to a "differentiated" state. Indeed, drugs like chloramphenicol may be more valuable in prevention than in cure.

Our results do not necessarily conflict with the view that dopamine deficiency is the primary cause of Parkinson's disease, because amine biosynthesis and function are dependent on protein containing carriers. The clinical effect of L-dopa administration may, however, not be attributable solely to the action of dopamine as a neurotransmitter. A direct effect of dopamine on nucleic acid synthesis has been demonstrated[16].

Our emphasis upon the beneficial effect of chloramphenicol on Parkinsonism is not meant to suggest a routine clinical use of the drug, but the results do indicate possible new approaches to a study of the pathogenesis and treatment of the disease.

Survival in Adult Mealworm Beetles (*Tenebrio molitor*) of Learning acquired at the Larval Stage

USING larvae of the beetle *Tenebrio molitor*, we tested the possibility that learning might survive through metamorphosis. This beetle shows a complete metamorphosis involving practically all parts of the body. Accurate information about the modifications of the epicuticle and its related structures in metamorphosis is available[1], but little is known about the modifications of the central nervous system.

The learning ability of the larva was compared with that of the adult of *Tenebrio* 27 years ago by Von Borell du Vernay, who found[2] no significant difference between the two stages. These findings were interpreted by him in accordance with the earlier observations of Bretschneider[3] on the "anatomical stability" of the mushroom bodies during the metamorphosis. Von Borell du Vernay suggested also that the "corpora pedunculata" could be

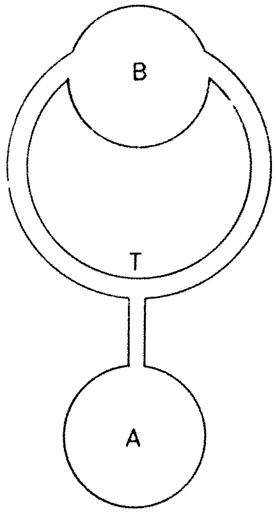

Fig. 1. The maze used for training the larvae and testing the adults. *A*, Starting point; *B*, goal; *T*, choice point. Total length of the path *AB*, 11 cm; width of the alleys, 4 mm for the larvae and 8 mm for the adults.

the anatomical site of memory. Vowles has recently shown that the "corpora pedunculata" in ants play a part in learning[4].

We trained larvae[5] and tested for persistence of the learned behaviour in the adults. A group of larvae, whose age homogeneity[6] was obtained by choosing animals with initial body weight in the range 8–15 mg, was split into two subgroups of one hundred each, the learning group L and the control group L_0. We used the simple technique of a two way maze (Fig. 1), the punishment being a bright light, the reward darkness. The larval and adult stages show a strong negative phototaxis. All animals passed through the maze once a day: the L group were punished immediately after a wrong choice, the L_0 group were not. Each animal lived in an individual box, and records were kept throughout its life. After each passage, the maze was changed so as to avoid clues deriving from previous use and was washed before being used again; bridges with photo-cells and thermistors assured the absence of light and temperature asymmetry between the two sides of the maze.

The learning group L was divided at random into two equal subgroups, the RL (right learning) and the LL (left learning) group: the RL animals were punished when the first three body segments had entered the left alley of the maze; the corresponding procedure was followed for the LL group. The number of choices made by the animals of the two groups, L, L_0, are given in Table 1.

The pupal stages were kept in the dark in their boxes, at room temperature, and at about 22° C and 50–60 per cent humidity. The duration of the pupal stage, in these conditions, averaged 17 days.

Table 1. RESULTS OBTAINED FOR THE FOUR GROUPS OF *Tenebrio*

		Observed number of choices towards the right	Observed number of choices towards the left	Total number of choices	Expected number of choices from chance	P-level
Larvae	RL	307	197	504	252	0·0005
	LL	194	277	471	235·5	0·007
Adults	RA	139	91	220	110	0·005
	LA	81	129	210	105	0·018
Control	L_0	304	309	613	306·5	> 0·95
	A_0	109	109	218	109	> 0·99

L, Larvae of the learning group; RL, larvae learning to go to the right; LL, larvae learning to go to the left.

A, Adults derived from larvae of the learning group; RA, adults which received training to go to the right in the larval stage; LA, adults which received training to go to the left in the larval stage.

L_0, A_0, Larvae and adults of the control group.

Adults of both groups were never trained; they were only tested. The last column gives the P-level obtained from the χ^2-test.

Thirty adults of the larval learning group and thirty of the control, selected at random at the end of metamorphosis, were passed daily without punishment through mazes similar to those that were used for the larvae, except that the width of the alley had been modified to maintain for the adults the same body-to-wall relationship. In this manner we obtained two samples of adults: adults A, the larvae of which had been trained, and adults A_0, which had not been trained. Table 1 shows the number of choices by each group towards right or left. The number of trials was less than with larvae, because the average life of the adult is shorter. The data clearly show that the adults A with previous experience of learning showed a significant tendency to perform as they had done as larva.

To show the absence of inherent tendencies to prefer one of the two directions in both life stages, we computed the correlation coefficient r between the choices towards right and left for each animal in the L_0 and A_0 groups. The r-value shows practically zero correlation ($r = 0·253$, $t = 1·420$, $0·10 < P < 0·20$).

There is therefore clear evidence that learning survives through metamorphosis. This agrees with the fact that at least some part of the brain remains relatively unchanged, for example, the corpora pedunculata and protocerebral bridge (Von Borell du Vernay[2]).

We thank Professor E. M. Eisenstein, State University of New York, and Professor J. Z. Young, University College London, for helpful discussions.

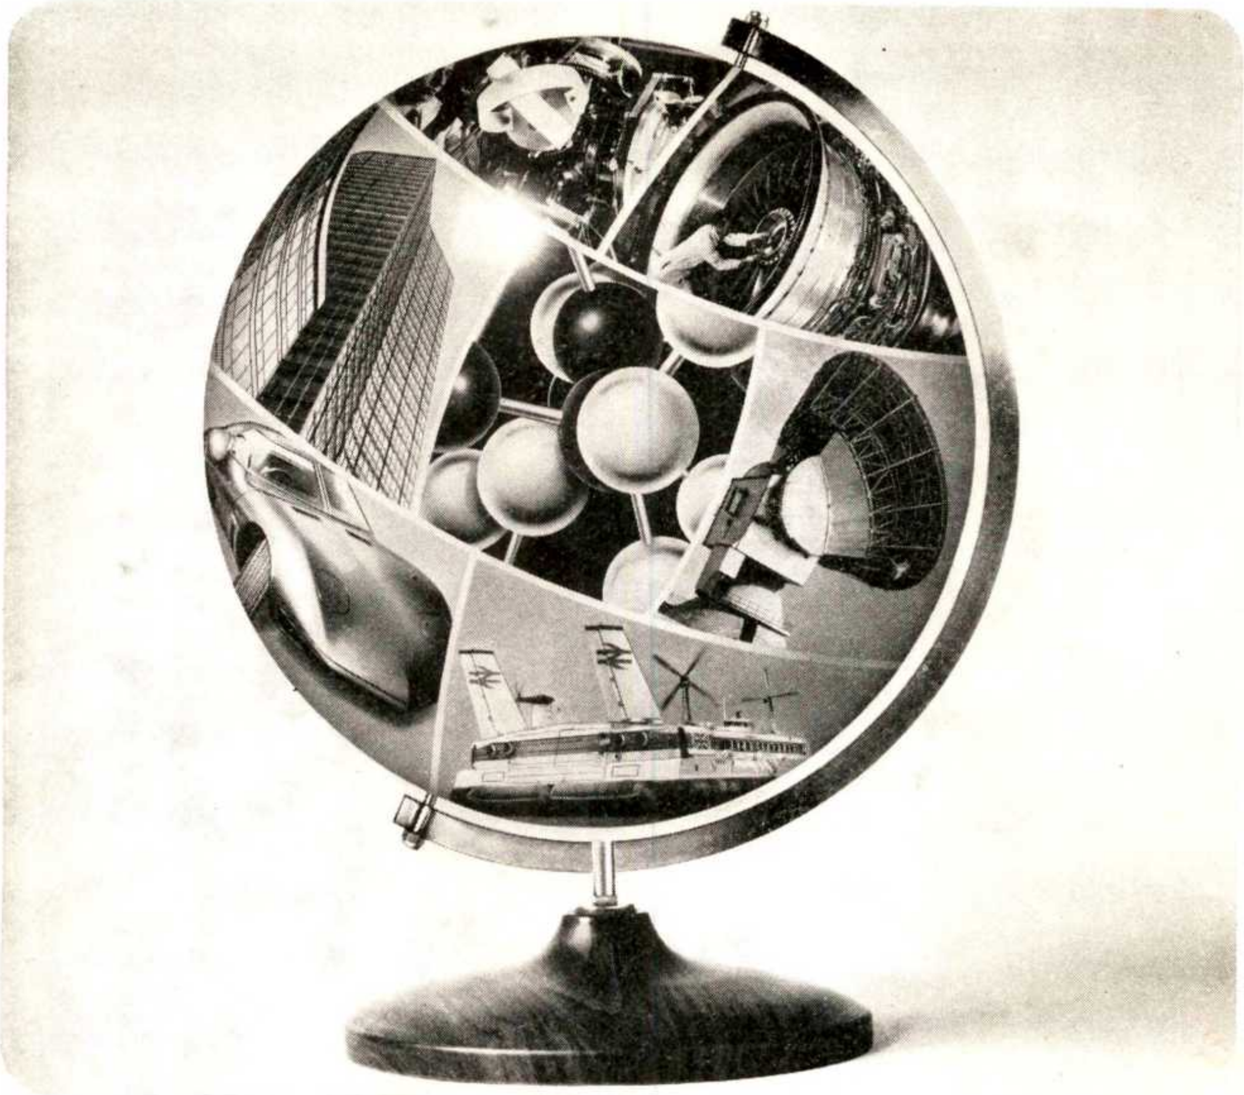
Gregarines: their Effect on the Growth of the Desert Locust (*Schistocerca gregaria*)

ALL stages of the desert locust *Schistocerca gregaria* are infected with a eugregarine *Gregarina garnhami*[1,2] (Fig. 1*a*). The morphology and life history of gregarines have been studied extensively, but little is known about the effects of gregarines on their invertebrate hosts.

The larvae of the mealworm *Tenebrio molitor* are normally unaffected[3] by heavy infestations of *G. polymorpha*, although pupal weight and length of larval life are influenced when other conditions are sub-optimal.

Lewis[4] has suggested that "a gregarine *Echinomera hispidia* may be responsible for the low number of *Lithobius forficatus* in damp woodlands" and Lipa[5] has concluded that serious damage is caused to the midgut epithelium of insects by gregarines. Except in cases of massive synchronous infection of sporozoites, the physical damage to epithelial cells is slight; eugregarines probably exert their greatest effect by acting as a physiological barrier between midgut cells and the digested food (Fig. 1*b*).



Tomorrow's world
depends on today's mathematics teachers.
If you are a maths graduate come and join them.

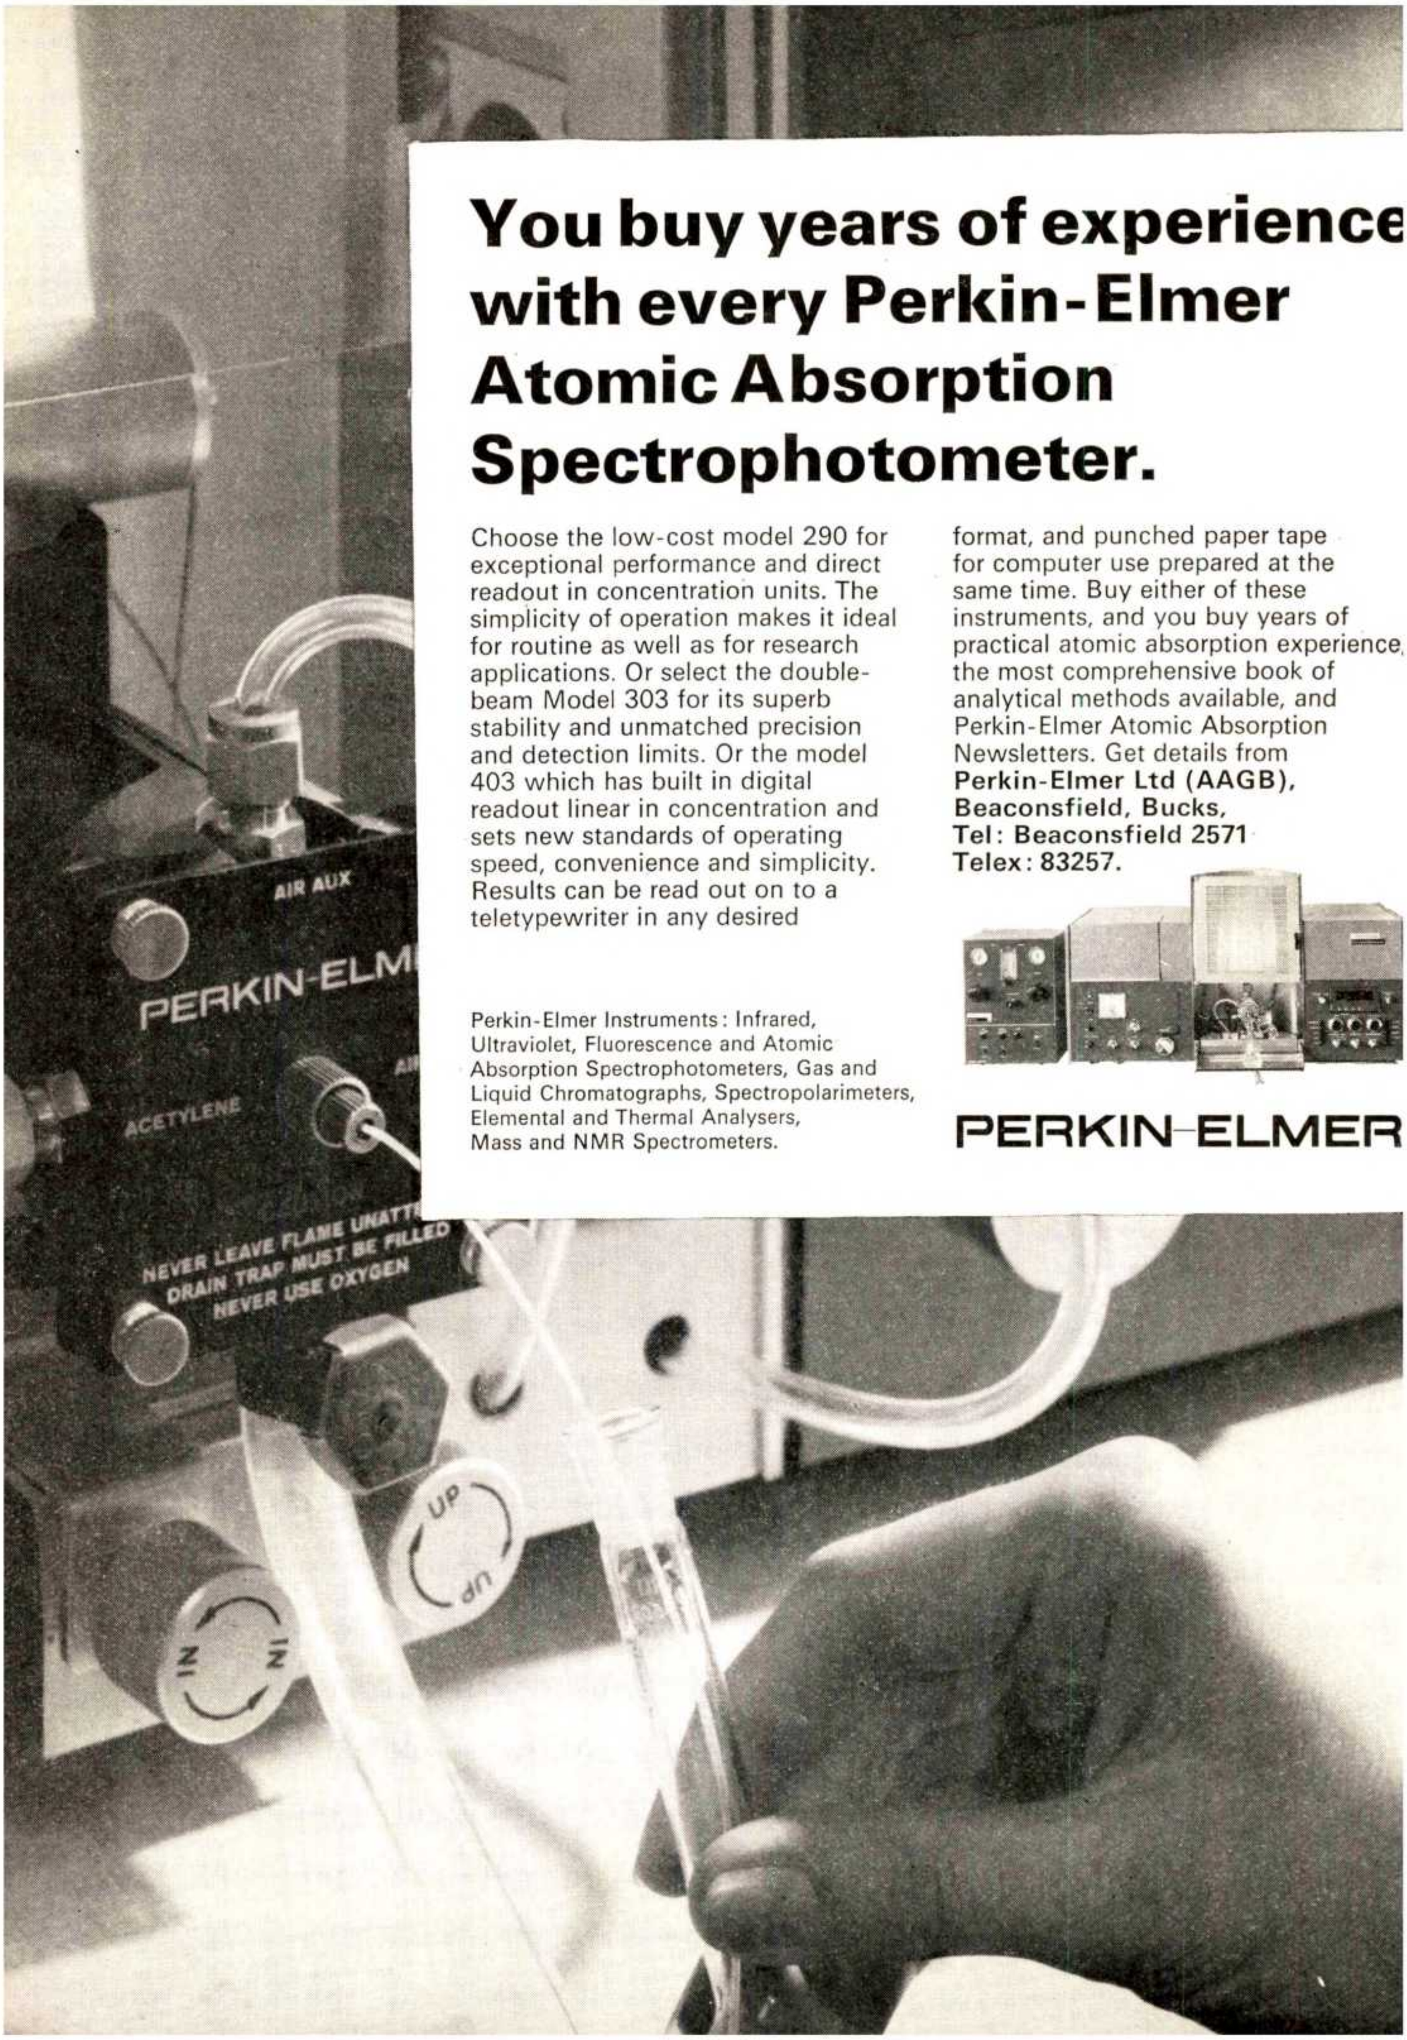
It's scarcely an exaggeration to say that the country's future depends on the quality of today's maths teachers. Technological advances depend on a sound understanding of mathematics. And that can only be gained from teachers dedicated to making their subject come alive. There's no room for boredom in modern maths lessons. And no chance of it in a modern teacher's world. Over 40% of maths and science graduates who started teaching seven years ago are already heads of departments. One in five graduates over 40 is a head teacher, while others put their teaching experience to good use in administration or inspection. Jobs for mathematics teachers are available in almost every part of the country. And there are long holidays.

Pay and Prospects. Starting salaries are competitive with those of other careers, ranging for graduates from £965 to £1,170. Looking forward, as head of a large department you could earn over £2,600; a deputy headship could take you above the £3,000 mark. Promotion, like responsibility, is seldom long in coming when you're a mathematics teacher. And if one is looking at long-term prospects one must look at the educational service as a whole: not all the jobs for which teaching experience is needed are in the schools. Want to find out more about teaching? Read our free booklet 'Careers in Education for Graduates'. Available from: The Department of Education and Science (Dept. N.2, Room 107), Curzon Street, London, W1Y 8AA.

Are you already in employment? Measure what you're doing now against teaching. Is it as interesting as you expected? Are the prospects as good? Are you in charge of your own daily activities in the way a teacher is? You can still come into teaching—you'll be *very* welcome.

Looking forward?

TEACH MATHS



You buy years of experience with every Perkin-Elmer Atomic Absorption Spectrophotometer.

Choose the low-cost model 290 for exceptional performance and direct readout in concentration units. The simplicity of operation makes it ideal for routine as well as for research applications. Or select the double-beam Model 303 for its superb stability and unmatched precision and detection limits. Or the model 403 which has built in digital readout linear in concentration and sets new standards of operating speed, convenience and simplicity. Results can be read out on to a teletypewriter in any desired format, and punched paper tape for computer use prepared at the same time. Buy either of these instruments, and you buy years of practical atomic absorption experience, the most comprehensive book of analytical methods available, and Perkin-Elmer Atomic Absorption Newsletters. The locusts used in this experiment came from a culture that has been maintained in the department for several years and originated from the Anti-Locust Research Centre, London.

To obtain hoppers that were free from gregarines, eggs were surface-sterilized by immersion in 70 per cent ethyl alcohol for 5 min, and left to hatch in sterile glass chambers.

Hoppers were grown in jars designed specially for maintaining parasite-free insects[6]. Five hoppers were placed in each jar, sharing a volume of approximately 1,000 cm³. When all the hoppers had moulted to the second instar (after 5–6 days) they were placed individually into 2 × 1 inch glass vials, randomized into two batches of 40 and designated *A* and *B*.

Batch *A* were offered barley shoots on which were placed gregarine sporocysts. Batch *B* were offered barley shoots free from sporocysts. After all the hoppers had eaten the barley they were returned to the jars, where they remained—four to each jar—until they had moulted to the fifth instar. They were then further subdivided—two per jar—until the end of the experiment. The hoppers were fed bundles of fresh barley shoots; a supply of moist fresh shoots was always available.

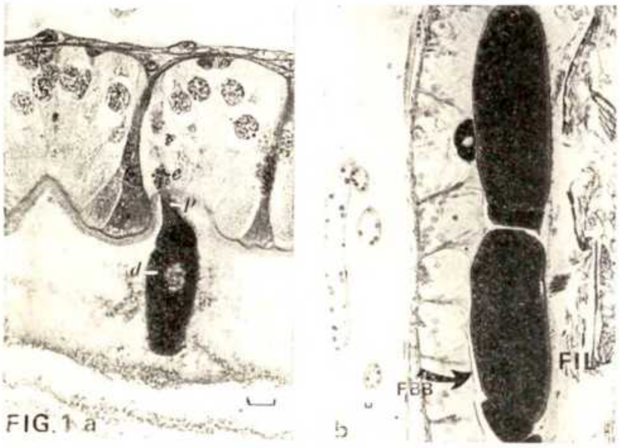

Fig. 1. *a*, L.S. of cephalont attached to midgut epithelium of *S. gregaria*: *e*, epimerite; *p*, protomerite; *d*, deutomerite. 8 μm section. P.A.S. celestine blue, Mayers haemalum and Orange G. Scale approximately 10 nm. *b*, L.S. of two sporonts in syzygy illustrating how such associations can act as a barrier between food in lumen (FIL), and free brush border (FBB) of epithelial cells. Just one such association could cover the free surface of some 500 intestinal cells. Stain as in *a*. Scale approximately 10 μm.

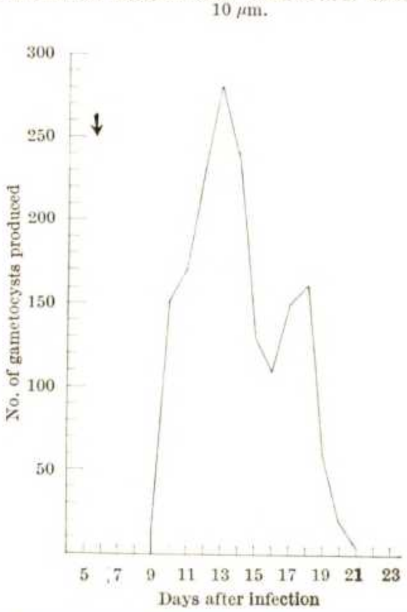

Fig. 2. The number of gametocysts produced by all infected locusts over the 23 days after exposure to sporocysts. The arrow shows when the first associations are found free in the intestine.

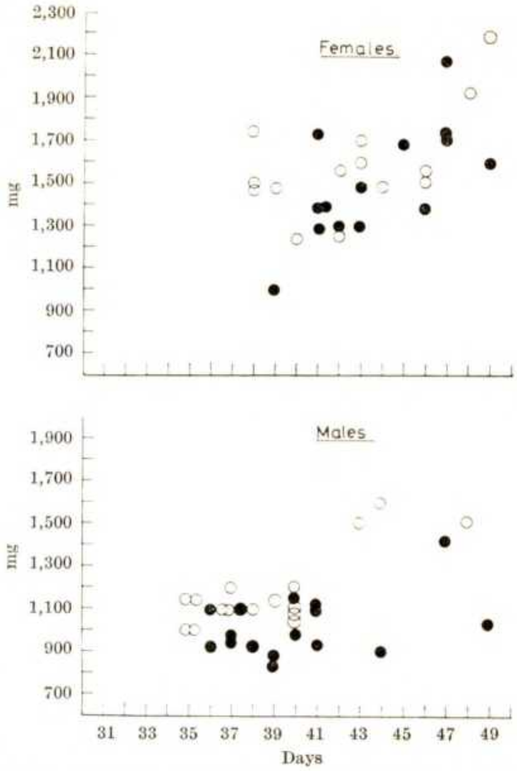

Fig. 3. Scattergrams of weights of fledglings against length of time from hatching to fledging for males I and NI bottom, and females I and NI above. ○, Not infected; ●, infected.

The jars were arranged in a circle around a 60 W electric light bulb, and the light period was controlled at 10 hours. The temperature inside the jars was 30° ± 2° C when the light was on, and 26° ± 1° C when it was off.

The degree of infection was checked in the live animals by examining the faecal pellets on consecutive days after infection; daily gametocyst production is shown in Fig. 2, and reaches a peak around 12–14 days after infection. Five infected hoppers were killed to check the degree of infection, which was found to be moderate (100–200 gregarines per locust). The weights of all the locusts were taken within a few hours of the final moult.

To study any changes taking place in infected gut cells, techniques similar to those used previously[2] were used.

Sixty locusts developed completely and soon after the final moult an analysis was carried out on the weight, and on the total length of nymphal life (Tables 1–3). There were two significant differences between sexes, the males being lighter in weight and having a shorter nymphal life than the females. Infection had no effect on the

The reason for this is not known. Scale on all photographs, approx. 10 µm.

length of nymphal life or on the weight of females ($F=0\cdot6681$). Infected males, however, were significantly lighter in weight ($F=7\cdot5341$).

Fig. 3 shows clearly that infected males are consistently lighter than non-infected males; it would be interesting to compare the effects of gregarines on both sexes in conditions less favourable to the host—for example, when food was in short supply.

Fig. 4 (*a–i*) shows a number of gregarines attached to individual midgut cells of *Schistocerca*. Cells that have gregarines attached to them show signs of displacement at their free ends, but it is not clear whether the displacement causes temporary or permanent damage; only in a small number of cells can degenerative effects be observed.

The following data were recorded from sections taken from a late instar hopper five days after infection with sporozoites and one day before a moult: (1) Cells without gregarines attached showing degeneration: many hundreds (Fig. 4(*f*)). (2) Cells with gregarines attached not showing damage: 45 (Fig. 4 (*a–e*)). (3) Cells with gregarines attached showing damage (basophilia): 2 (Fig. 4 (*h*)).

Gregarines remain attached to host cells for relatively short periods of time (5–8 days); they then become detached and form associations that remain in the midgut and continue to grow. Fig. 2 shows the daily production of gametocysts. Detached pairs in association can be found after 5–6 days (arrow, Fig. 2).

The gregarines shown in Fig. 4 (*a–e*) had been attached for 4–6 days. Fig. 4 (*g*) is the epimerite of a large gregarine eight days after infection. In the desert locust, 20 per cent of the midgut cells are replaced at each moult[3]. Biddeman, quoted by Wigglesworth[7], states that there is complete replacement of the midgut epithelium every 48 hours in *Tenebrio molitor*. It would therefore seem that even when eugregarine infections are heavy there will not be sufficient time for significant damage to develop.

Although the locusts were grown in optimal conditions with little competition for food or roosting sites, only moderately heavy infections of gregarines had a significant effect on the weight of the fledgling males. The degree of infection was certainly not as heavy as that usually encountered in routine laboratory stocks of locusts, or in an experiment where more than 10,000 gregarines per locust did not seem to affect moulting or feeding.

The locust thus differs from the mealworm *Tenebrio molitor* in which massive infestations of *Gregarina polymorpha* have no significant effect on larvae grown in optimal conditions.

Lipa's photographs[5], which purport to show damage caused by gregarines, reveal such severe processing damage that determination of gregarine damage is impossible. Because the parasite's survival depends on the survival of the cell to which it is attached, it is unlikely to destroy its essential anchor. Although attached gregarines may impair the functioning of epithelial cells directly, it is more likely that gregarines exert their effect on the physiology of digestion and absorption by presenting a barrier between the free brush border (Fig. 1*b*, FBB) of the intestinal cells and food in the lumen (Fig. 1*b*, FIL).

Lewis's hypothesis[4] that a gregarine (*Echinomera* sp.) may be responsible for the absence of *Lithobius* from a particular habitat does not seem tenable, particularly because his centipedes contained low numbers of gregarines and the differences between numbers of gregarines in both populations were very small. It would seem that some other factor must be responsible for its scarcity from certain habitats.

Effect of Cycloheximide and Actinomycin *D* on the Behaviour of the Headless Cockroach

AVAILABLE evidence suggests that although actinomycin *D* and cycloheximide inhibit long term memory in mice and goldfish, these antibiotics have little or no effect on the primary acquisition of a new task[1,2]. It was therefore very interesting that Brown and Noble[3] should report that cycloheximide inhibited the ability of a headless cockroach to avoid an electric shock by keeping its leg raised[4]. This behavioural inhibition seems to be correlated with the extent of inhibition of protein synthesis[5]. There are many possible explanations, but Brown and Noble reported no change in sensitivity to the shock stimulus when cycloheximide was given, so that this factor can be ruled out. The activity of the leg, however, was greater after cycloheximide had been given. This suggested that if this drug caused increased activity, it would interfere with the achievement of a criterion (two shocks or less in 3 min) that depended on a relatively quiescent state. We report here the results of an attempt to ascertain whether cycloheximide affects learning performance by the increasing activity of the leg. As well as cycloheximide, we have investigated the effects of actinomycin *D*.

Individuals of *Periplaneta americana* were anaesthetized with carbon dioxide, and the dorsal surfaces were attached to the underside of glass rods, 3/8 inch in diameter and 8 inches long, with warm sticky wax (L. D. Caulk Co., Milford, Delaware). All legs, except the right prothoracic, were covered by a piece of gauze, the ends of which were embedded in Dentina bite wax (Browning's Dental Supply Co., Hull, England) attached to the opposite side of the glass rod. Cockroaches were decapitated and wounds were sealed with 'Vaseline', which was covered 1 h later with flexible collodion (USP, Fisher Scientific Co.) to prevent leakage. The anal area was also sealed with warm sticky wax. The free prothoracic leg of each cockroach was wired with silver wire, 0·004 inch in diameter, according to the method of Eisenstein and Cohen[6], so that the leg received a shock because it completed an electrical circuit when lowered into a saline solution. The direct current voltage in the circuit was controlled between 15 and 20 V, and 10 to 40 μA was registered on the meter. Cockroaches were trained to a criterion of two shocks or less per minute for 3 consecutive minutes, after which the trained leg was primarily in a flexed position.

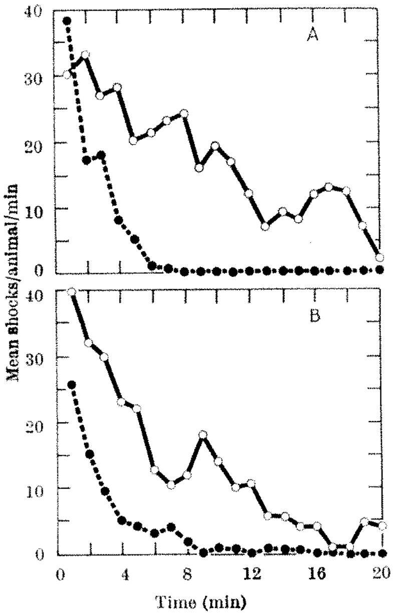

Fig. 1. Effect of cycloheximide and actinomycin *D* administered before training. *A*, Eight cockroaches received two 5 μl. injections of insect saline while eight others received a solution of 0·9 mg/ml. of cycloheximide in insect saline. After 5 min, training commenced (○—○, cycloheximide; ● - - - ●, saline control). *B*, Eight cockroaches received 5 μl. of 1 mg/ml. of actinomycin *D* in insect saline, while eight others received a solution of 0·8 mg/ml. of mannitol in insect saline. After 5 min, training commenced (○—○, actinomycin *D*; ● - - - ●, mannitol saline control).

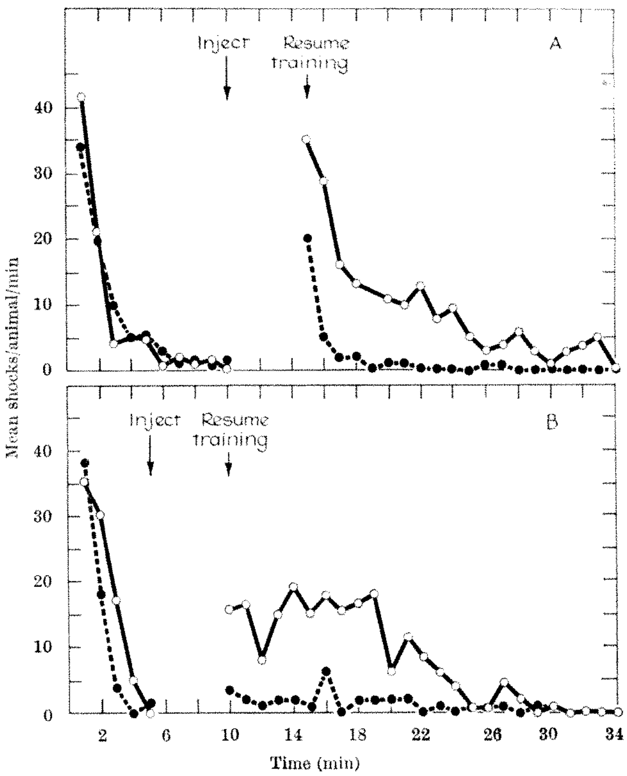

Fig. 2. The effect of cycloheximide and actinomycin *D* administered after training. *A*, After 10 min of training, eight cockroaches received cycloheximide while eight others received saline injections as described in Fig. 1*A*. Training resumed after 5 min (○—○, cycloheximide; ● - - - ●, saline control). *B*, After 5 min of training, eight cockroaches received actinomycin *D* while eight others received mannitol saline injections as described in Fig. 1*B*. Training resumed after 5 min (○—○, actinomycin *D*; ● - - - ●, mannitol saline control).

Drugs were administered in insect saline (0·16 M NaCl; 0·0018 M $CaCl_2$ $2H_2O$; 0·002 M KH_2PO_4; 0·0018 M K_2HPO_4) (ref. 7) containing either 1 mg/ml. of actinomycin *D* (Nutritional Biochemical Corp.) or 0·94 mg/ml. of cycloheximide (Sigma). Controls for the actinomycin *D* experiments were injected with a solution containing 0·8 mg/ml. of mannitol in insect saline while the controls for the cycloheximide experiments received insect saline. Injections were made through the ventral surface of the prothorax using a 10 μl. Hamilton syringe. All solutions were coded and all experiments were conducted blind.

Typical consequences of injection (Fig. 1*A* and *B*) were similar with both drugs. Animals injected with either drug were more active and received more shocks than control animals at all points. The effects of cycloheximide agree with the data of Brown and Noble[3,5]. Clearly the animals receiving cycloheximide or actinomycin *D* experienced delay in acquiring the avoidance behaviour which minimizes the number of shocks (that is, a raised leg) and throughout the training procedure they received more shocks.

To test whether the drugs affected the primary acquisition of the task or the activity of the leg, these were administered after the cockroaches had achieved criterion. The learning curves are shown in Fig. 2*A* and *B*. After training, the animals were injected with either the drug or the control solution and 5 min later training was resumed. Fig. 2 shows that both cycloheximide and actinomycin *D* interfere with the performance of the trained legs. This was accompanied by increased leg activity that led to increased shocks. The number of shocks decreased rapidly in the group that did not receive drugs, while the treated cockroaches experienced a much slower decline in the number of shocks per minute.

These results confirm and extend those of Brown and Noble[3,5], who showed that cycloheximide, a potent inhibitor of protein synthesis, brought about a decrease in the acquisition of avoidance behaviour by this cockroach preparation. We have also shown that actinomycin *D*, a potent inhibitor of RNA synthesis, has similar effects. The mechanism of action of the drugs is not clear, however. It is possible that the synthesis of RNA and protein is essential for primary acquisition of a new task, but it is also possible and more probable that the interference with learning performance is secondary to the learning process itself, and occurs because these drugs increase leg activity. This activity interferes with the quiet state essential to enable the leg to remain raised so as to avoid shocks. Eisenstein[8] has also suggested this possibility. This interpretation is strengthened by the fact that a trained leg is also prevented from performing this task by these two drugs. While it is possible that handling during injection caused amnesia so that the preparation had to relearn the task—a process which could be dependent on the synthesis of RNA and protein—it seems more likely that the drugs affected performance by stimulating leg activity. The mechanism by which leg activity could be increased is not known.

Lytic Enzyme produced *in vitro* by Insect Cells: Lysozyme or Chitinase?

THE mechanism of immunity in insects is very poorly understood: no immunological reaction of the antigen–antibody type is known[1]. Bactericidal or bacteriolytic[2,3] properties of insect tissues, body fluids or even secretions have been reported, but in the absence of precise biochemical data the nature of the substance responsible has not been established.

During the *in vitro* cultivation of insect cells, we noticed that the cells produce a factor which destroys several kinds of microorganisms. We have tried to characterize this substance produced *in vitro*. The insect cell lines we have used were previously developed by one of us[4] from the embryos of two cockroaches: *Periplaneta americana* L. and *Blabera fusca* B. An attempt was made to grow the symbiotic bacteria of *Periplaneta* in these cell cultures[5]. Some of the bacteria were lysed rapidly on association with the cells. Furthermore, on several occasions, these same cells were able to resist different infections by bacteria or fungi.

In studying this lytic activity, therefore, we chose an EP$_a$ cell strain (from *Periplaneta americana*) because of its high resistance to infection. The cultures were grown at 30° C in Roux bottles containing 100 ml. of medium S19 (ref. 6) with a *p*H indicator and without any antibiotic. The initial inoculum was about 10^9 cells. When the *p*H had fallen to 6·5, the medium was collected, filtered through 'Millipore' membranes to remove the cells and dialysed against a *p*H 6·5 phosphate buffer.

Looking for the bacteriolytic substance in the metabolized medium, we tried to establish and then to measure a possible lysozyme-like activity. We used the standard turbidimetric assay against a suspension of killed cells of *Micrococcus lysodeikticus*[7]. The final culture medium, unlike the fresh medium, was significantly bacteriolytic; its enzymatic activity was equivalent to that of a 10–20 µg/ml. solution of hen egg-white lysozyme. This activity disappeared when the cells were ground in the medium. Thus the lysis of *Micrococcus lysodeikticus* may be accounted for by the production and release of an enzyme in the supernatant of EP$_a$ cell cultures. This enzyme has thus the same behaviour as hen egg-white lysozyme (EC 3.2.1.17) in similar conditions, and hydrolyses the mucopolysaccharide found in bacterial cell walls, a polymer of alternating residues of N-acetylglucosamine and N-acetylmuramic acid. A very similar peptidoglycan has been found in the walls of the symbiotic bacteria of cockroaches[8], which would explain their rapid destruction in the medium of EP$_a$ cell cultures.

We also tried similarly to correlate the lysis of yeasts and fungi with the occurrence of a specific enzymatic activity. It is well known that their cell walls are composed chiefly of chitin, a polymer of N-acetylglucosamine[9]. Chitin, however, is usually not a good substrate for enzymatic determinations and it is more convenient to use low molecular polymers of N-acetylglucosamine[10]. We found a highly significant activity against such substrates in the medium metabolized by EP$_a$ cells. For example, an enzymatic preparation which (measured against *Micrococcus lysodeikticus*) corresponds to a 1 µg/ml. solution of hen egg-white lysozyme is able to hydrolyse 300 µg of chitopentaose in less than 4 h. To obtain a similar result with hen egg-white lysozyme, it is necessary, in the same experimental conditions, to use an enzyme concentration which is twenty times as high.

We conclude that the lytic enzyme produced *in vitro* by our insect cells is more like a chitinase (EC 3.2.1.14) than a true lysozyme, for it is a poor muramidase and an excellent chitinase with *M. lysodeikticus* cells and chitopentaose as substrates. With these same two substrates and in similar experimental conditions, an exactly inverse situation was found for lysozymes of vertebrates[11].

Plant Pigments identified in the Common Blue Butterfly

FLAVONOIDS are rare in the animal kingdom, but Ford[1], using a simple colour test, suggested that they were present in a number of butterflies. A difficulty in characterizing the pigments is the fact that a large number of specimens, of the order of hundreds, is required, and it is not always possible to obtain one species in such large numbers. Morris and Thomson[2], using some 400 specimens, identified tricin and a glycoside of this flavone as well as a glycoside of another flavone, orientin, from the wings of the marble white butterflies *Melanargia galathea*. They found[3] that the small heath butterflies *Coenonympha pamphilus* contained tricin both free and as glycoside but not orientin. The flavonoids seem to be obtained by the insects through the caterpillars feeding on a particular food host. Carotenoids, on the other hand, are well known in animals, and Goodwin[4] has suggested that insects accumulate their dietary carotenoids as such or that they may be altered to form other carotenoids not found in the insects' food. A number of specimens of the common blue butterfly *Polyommatus icarus* Rott. were collected both in France and in England with a view to characterizing the flavonoids and the carotenoids and to comparing these with their food plants. One hundred specimens of *P. icarus* from Box Hill, Surrey, were feeding on rest harrow *Ononis repens* and those from St Martial, France (800 specimens), on a species of *Anthyllis*; both plants are members of the Leguminosae.

Flavonoids were extracted by conventional methods[5], refluxing with 70 per cent methanol for 2 h. The extract was evaporated *in vacuo* at about 40° and the residue dissolved in a small volume of 70 per cent methanol. This was then streaked on Whatman No. 1 paper and run in various solvents (Table 1). The characteristic colours under ultraviolet light with and without ammonia fumes were noted. R_f values and absorption spectra were compared with those given by Harborne[5]. Not all the bands that were obtained after chromatography in 30 per cent acetic acid were identified, because some were found in too small amounts. The compounds that were tentatively identified in the French butterflies were the free flavonol 3-O-methyl-kaempferol and the flavonol glycoside quercetin 3,4′-diglucoside (Table 1). A flavone glycoside and an isoflavone with properties shown in Table 1 were also obtained, but it was not possible to identify them further.

Table 1. FLAVONOIDS IN THE FRENCH COMMON BLUE

Band	Colour in ultraviolet $-NH_3$	Colour in ultraviolet $+NH_3$	R_f values in: 30 per cent acetic	R_f values in: 'Forestal'	R_f values in: Phenol PhOH	$\lambda_{\max}$ in ethanol	Compound
I	Blue	Blue	0·13	0·90	—	~265, 272, ~279, 320	Isoflavone*
II	Brown	Green	0·49	0·74	0·85	267, ~295, 347	3-O-Methyl-kaempferol
III	Brown–yellow	Bright yellow	0·43	0·67	0·27	257, ~267, 295, ~355	Quercetin 3,4′-diglucoside
IV	—	Green	0·66	0·70	—	272, ~279, 330	Flavone glycoside*

3-O-Methyl-kaempferol	−	+	−
Quercetin 3,4′-diglucoside	−	+	−
Flavone glycoside	−	+	−

Carotenoids were extracted in methanol and partitioned with diethyl ether. The ethereal extracts were reduced *in vacuo* at about 40°, taken up in a small volume of *n*-hexane, separated by column chromatography and identified by our usual methods[6]. The results for carotenoids and flavonoids in the French and English butterflies of *P. icarus* and those of *O. repens* are given in Table 2. We could not obtain the food plant of the French species.

Phytoene was found in insects of both countries as well as in the food plant *O. repens*. As far as we know, this is the first record of this colourless C_{40} polyene in insects even though it is found quite abundantly in a great number of plants. Contrary to what was found in certain other insects, such as *Schistocerca gregaria* and *Locusta migratoria migratoroides* R. and F.[7], the carotenoids of the food plants of *P. icarus* are unchanged in the imagines even though not all the carotenoids present in *O. repens* were identified in the imagines. As for the flavonoids, the unknown isoflavone was obtained in the French butterflies and in *O. repens* but not in the English ones. Flavonoids were not identified at all in the English butterflies, but small amounts were present because only 100 specimens were used. Isoflavones are found mainly in the Leguminosae, and the presence of one such compound in the butterflies shows that the compounds are obtained by the insects from the particular food plant. The flavonols quercetin and kaempferol were identified in the French butterflies, though not found in *O. repens*. These compounds are well known in closely related members of the Leguminosae[8] and it is quite likely that they are also found in *Anthyllis*. The larvae of *M. galathea*, however, are known to feed on certain grasses that contain tricin and orientin but lack quercetin. Harborne[5] has explained the absence of orientin in *C. pamphilus* in suggesting that, because orientin contains a catechol nucleus, it may be more readily metabolized by insects. This does not, however, explain its presence in *M. galathea* and, further, in our investigation we identified quercetin, which contains a catechol nucleus. Orientin might have been present in small amounts and not detected in *C. pamphilus*, as was the case with the English imagines in our investigation in which no flavonoids were identified, because the sample was smaller.

Suspected Insecticide Resistance Mechanism in the Peach–Potato Aphid

POPULATIONS of the peach–potato aphid, *Myzus persicae* (Sulzer), that have survived exposure to organophosphorus insecticides are sometimes received for identification in the British Museum (Natural History). Microscopical examination reveals that resistant populations have better developed lateral abdominal tubercles on segments 2–4 than susceptible populations. The resistance of *Myzus persicae* to demeton-methyl is not stable, a twenty-five-fold resistance being acquired during seven clonal generations exposed to it and lost during thirty generations not exposed[1]. Experiments being done at Rothamsted Experimental Station (C. J. B., in preparation) made it possible to study the morphology of aphids from susceptible and resistant aphid populations and to compare them with each other and with susceptible members of a previously resistant population.

Large lateral abdominal tubercles are usually present on abdominal segments 2–4, and sometimes 1 and 5, of the spring migrants of *Myzus persicae* that develop on peach trees. These tubercles are usually much less well developed or may not occur on the summer forms that develop on herbs. The tubercles can be difficult to detect in the wingless forms because both the tubercles and the surrounding rugose cuticle are transparent. The tubercles are evident in the winged females as the transparent tubercles are placed on the otherwise dark lateral sclerites. Winged females only were considered, but there is no reason to think that they differ from the wingless females in this character, except for the ease of observing the tubercle. Occasionally, a spinule with an enlarged base, resembling a small but pigmented tubercle or a pale ill-defined area, occurs in the position on the lateral sclerite where the tubercle occurs when present. The traces are regarded as incipient or rudimentary tubercles and have each been scored as half a tubercle in Table 1.

Table 1 summarizes the data from fourteen samples of *Myzus persicae*. The first two samples are spring migrants from peach in which each specimen usually has from four to six large tubercles on lateral abdominal sclerites 2–4. Sample 2 is the combined data from six separate collections in the area within the space of a few days. Samples 3–7 are from populations known to be susceptible to organophosphorus insecticides and the specimens seldom bear more than one, often small, lateral abdominal tubercle, the means for the populations ranging from 0·00 to 0·61 lateral tubercles per specimen. No lateral tubercles were observed in population *S* at Rothamsted in 1967 (samples 4 and 5). Sample 6 is the combined data for three small samples taken at about weekly intervals while population *S* was infested by an internal hymenopterous parasite. The three successive samples had means of 0·38 (three tubercles on eight specimens), 0·64 (nine in fourteen) and 0·71 (five in seven) tubercles per specimen. No internal parasites were observed in any of the specimens of sample 6, but some of the aphids may have occluded parasite eggs. Sample 7 was taken after the parasites had been eradicated and lateral abdominal tubercles were again absent. Samples 8–10 are of the corresponding insecticide resistant populations. Samples 13 and 14 are also from populations known to resist organophosphorus insecticides. The specimens from the resistant populations usually bear at least one lateral abdominal tubercle and the means for the populations range between 0·75 and 2·2 tubercles per specimen. Samples 11 and 12 are from the same population as 9 and 10 but were taken about two years after it had lost its resistance, and had means of only 0·04–0·07 tubercles per specimen.

The seventh and eighth abdominal tergites may also bear tubercles resembling those on the lateral sclerites, but placed dorsally. These tubercles have been called "spinal tubercles"[2], and are often present in aphid genera that deform the leaves of Rosaceae[2]. The tenth and eleventh columns of Table 1 summarize the occurrence of spinal tubercles. Spinal tubercles are much better developed in the spring forms (samples 1 and 2) which develop on peach than in the summer forms (samples 3 to 14). They are not clearly correlated with insecticide resistance, for instance, if there is any difference Russell's[3,4] susceptible population *NC* has more spinal tubercles than his resistant population *RR*. The known resistant populations of *Myzus persicae* summer forms have means of 0·50 to 0·92 spinal tubercles per specimen, and the known susceptible populations have a mean between 0·00 and 0·80 tubercles per specimen. The Rothamsted population *R* did not lose its spinal tubercles when it lost its resistance, and the successive means of 0·50, 0·58 and 0·49 make it improbable that the loss of resistance is from contamination of the culture with specimens from population *S*.

The function of the lateral abdominal tubercles is not established, but there is circumstantial evidence that they are concerned, with wax excretion. The lateral abdominal tubercles of the fundatrices of *Dysaphis pyri* are very large and have "distinct granular facies which suggest the pore plate of a wax gland group"[6]. The wax, or triglyceride[5] secreting organs characteristic of aphids, the siphunculi (=cornicles), are considered to be modified lateral abdominal tubercles. The siphunculi are relatively longer in the more resistant populations as indicated by the last column of the table. Resistant populations have

14	Capsicum	Poeldyk, Netherlands	September 1969	F. Baranyovits	Resistant	13	18	1·38	12	0·92	0·76

the siphunculi : antennal segment III ratio with means from 0·74–0·76 and susceptible populations from 0·66–0·74. The mean for population *R* dropped to 0·66 when it lost its resistance. Comparable figures are not given for the spring migrants because their siphunculi are cylindrical and not clavate like those of the summer forms. It is possible that the mechanism of insecticide resistance in the populations which we studied is to excrete the insecticide in association with wax or lipid, through the lateral abdominal tubercles or the siphunculi. The mechanism may have evolved for the disposal of waste products arising from the destruction of the eggs of parasites or for secreting a substance repellent to parasites. If the lateral tubercles are involved in insecticide resistance, the records of considerable resistance on peach trees in the spring[7,8] are not surprising because the spring forms *Myzus persicae* on peach usually have well developed tubercles.

In addition to material reared at Rothamsted, Dr F. Baranyovits, Mr J. P. Doncaster, Dr D. Hille Ris Lambers and Dr G. E. Russell have kindly provided specimens for study.

Vegetative Hybridity in *Phytophthora infestans*

Phytophthora infestans, the fungus that causes blight in potatoes, probably originated in Mexico[1], where two sexually compatible mating groups (A_1 and A_2) occur with equal frequency and oospores, resulting from normal sexual reproduction, are produced[2]. Elsewhere, by contrast, only one mating type (A_1) of the species has been recognized, so that in this situation the sexual stage of the fungus is not considered to have a role in the development of blight[3]. *P. infestans* is variable and highly adaptable to its different host genotypes, and much potato breeding experience shows that, even outside Mexico, the fungus adapts remarkably rapidly to varieties that bear *R*-genes from the wild species, *Solanum demissum*[4]. Indeed, it now seems clear that no *R*-gene resistance can be expected to last for more than a few years, for up to eleven specificities occur frequently in the population of *P. infestans* in Britain[5].

The question is: how do new and sometimes very complex races originate where the fungus is functionally asexual ? It is usually assumed that the accumulation of mutations is responsible, but this view raises obvious difficulties, though mutations, both natural and induced[6,7], do undoubtedly occur. The adaptability of the fungus suggests the presence of some sort of system of genetic variability. Such a system has now been found and is described here. Briefly, I show that mixtures of races with different specificities, say *a* and *b*, grown together on a susceptible host, yield new races pathogenic to R_aR_b hosts which are themselves immune to the original *a* and *b* races.

I use the conventional nomenclature whereby a specificity in the fungus is assigned a number that corresponds to the *R*-gene whose hypersensitive reaction it is capable of overcoming. Race 1, 2 thus attacks potatoes that are R_1 or R_2 or R_1R_2 but not clones that carry R_3 or R_4 and so on (which are hypersensitive to that race). Races are identified by a set of differential host clones of known *R*-gene constitution. For example, the race 1, 2, 3, 4, 7, 10 could be identified by virulence towards three clones $R_1R_2R_3R_4$ and R_7 and R_{10} and by the evocation of hypersensitive responses on clones carrying R_5, R_6, R_8 and R_9.

Briefly, the main result was that race 1, 2, 3, 4, 7 was obtained by mixing race 4 with race 1, 2, 3, 7 and race 1, 2, 3, 4, 7, 10 was derived from a mixture of race 3, 4, 10 and race 1, 2, 3, 7. The races 4 and 3, 4, 10 (both originally from cv. 'Majestic') were maintained on an R_4 host while the two isolates of race 1, 2, 3, 7 came from and were maintained on cv. 'Pentland Dell' ($R_1R_2R_3$). Suspensions of sporangia (in cold distilled water) were used in the combinations indicated to inoculate a series of test leaves, namely three tester clones, possessing the genes R_4, $R_1R_2R_3$ and $R_1R_2R_3R_4$ respectively, and 'Pentland Dell'. Large single drops of the mixtures (races 4 + 1, 2, 3, 7 or races 3, 4, 10 + 1, 2, 3, 7) were applied to the bases of the leaves and infection of all but the $R_1R_2R_3R_4$ leaves was successful. When the lesions were large enough, the inoculated half of each leaf was discarded and a sporangial suspension was prepared from the remainder. With each test series, half of the suspension from the R_4 host was added to that from the $R_1R_2R_3$ host and the remainder to that from 'Pentland Dell'. These mixtures were then applied to the series of tester leaves. In contrast to the first cycle of inoculations, growth occurred on all the leaves and transfers from each leaf to $R_1R_2R_3R_4$ leaves proved positive, though sometimes weak. After two subsequent transfers through $R_1R_2R_3R_4$ leaves, the races present were confirmed on the complete differential host series. Isolates derived from the mixture of races 4 and 1, 2, 3, 7 proved to be race 1, 2, 3, 4, 7 and those from races 3, 4, 10 and 1, 2, 3, 7 were race 1, 2, 3, 4, 7, 10. The four original isolates and the new races showed no alteration in racial constitution while undergoing four series of transfers on the differential hosts.

It is therefore established that mixtures of races grown together on a susceptible host combine genetically to produce new races that have the sum of the parental specificities. The mechanism is obscure but, because the zoospores of *P. infestans* are uninucleate[8], nuclear fusion is implied. This sort of genetic combination contrasts with the coexistence of races in mixtures without combination[5,6], and its frequency is still unknown. My several other experiments have sometimes succeeded and sometimes failed. For example, race 1, 2 has been produced from mixing race 1 with race 2 and race 2, 3, 4 from mixing the same race 2 with race 3, 4. In simultaneous trials, however, mixtures of the race 1 with race 2, 4 or race 3, 4 and mixtures of the race 2, 4 with race 3, 4 showed no combination. So far, then, the evidence in favour of vegetative hybridity in *P. infestans* is strong; there is no evidence yet of genetic recombination.

From the plant pathological viewpoint, these results are significant because they show that any susceptible potato variety that harbours two or more complex races may generate still higher levels of complexity. The extraordinary complexity of blight races in Britain revealed in a recent survey[5] is thus more readily understood than would be the case if the accumulation of mutations alone were responsible.

It may seem surprising that this "hybridization" behaviour has not been found previously. The reason seems to be that, in mixture studies (of which there have been several[7,9]), investigators have always tested the products on the "parental" differentials and not on the more complex differentials required to detect hybrids. McKee, however, has observed[9] that infection rates by zoospores derived from mixtures were higher than expected, a result that is at least compatible with the occurrence of hybridity.

GENERAL

Generation of Hypotheses and Theories

THE view that induction is an operation of valid inference of the same kind as deduction, expounded notably by John Stuart Mill, has been rightly rejected by modern scientists and philosophers. Instead, the growth of scientific understanding is looked on as a hypothetico-deductive activity. According to this view, hypotheses or theories are created, subsuming far more than the known facts they are intended to explain; they are tested for internal logical consistency and compatibility with the known facts; and implications are deduced from them for test by further observation or experiment. If such a test is adequately carried out and gives a negative result, the theory is scrapped or, alternatively, modified so as to be compatible with the new facts. Thus theories (if they have an adequate degree of generality) cannot be absolutely verified, though they can be absolutely falsified. Supporting evidence can corroborate them—strengthen our reasons for believing that they are true—but not verify them.

This much would be accepted, I think, by most working scientists. But protagonists of the hypothetico-deductive view of scientific method, in reacting against Mill's account of induction, have taken an extreme position which is untenable and also inhibits them from consideration and study of what is the central and most interesting aspect of induction, namely, the generation of the hypotheses and theories themselves. Popper[1], for example, writes "... there is no such thing as a logical method of having new ideas, or a logical reconstruction of this process. My view may be expressed by saying that every discovery contains an 'irrational element' ...". Hempel[2] writes: "There are, then, no generally applicable 'rules of induction', by which hypotheses or theories can be mechanically derived or inferred from empirical data. The transition from data to theory requires creative imagination." And Medawar[3] says "although one can put oneself in the right frame of mind for having ideas and can abet the process, the process itself is outside logic and cannot be made the subject of logical rules".

Even if it were true that no completely rational account could at present be given of any inductive operation, it would be both unjustified and conducive to the blocking of enquiry to assert as a matter of principle that there could be no such account. To do so is, indeed, to evade the key issue in the "logic of discovery". But in fact, not only in science but also in everyday thinking, rules are constantly employed in hypothesis formation. A child throws a stone and sees it sink in the pool—he makes the (deductively invalid) inference that all stones if dropped on water will sink. He has used a rule of abstraction and generalization which, formulated in the language of first-order predicate logic, reads: from $P(a)$ infer $(x)P(x)$; that is, from the fact "the object a has the property P" generate the hypothesis "all objects have the property P". Not only is this simple rule all-pervasive in science and thought, but its power can be judged from the fact[4] that, applied to relations instead of properties, and implemented as the sole inductive principle in a computer program, it has generated a remarkably close approximation to the axioms of group theory on the basis of only ten elementary facts about two simple mathematical groups.

This example is a clue to where one might fruitfully look for the discovery of rules of induction, for abstraction plus generalization is just the inverse of a standard rule (instantiation) of deductive inference, namely: from $(x)P(x)$ infer $P(a)$. And in fact, in spite of accepting Popper's dogmatism, Medawar seems to be dimly aware of this possibility, for he says[3] that "nowadays the tendency is to use 'experimentation' to stand for the acts used in testing a hypothesis, leaving 'induction' as a vague word to signify all the various ways of travelling upstream of the flow of deductive inference".

The process of abstraction, applied in the language of higher-order logic, is enormously powerful in the generation of new concepts. For example, suppose in some domain of phenomena involving a 2-place relation denoted by R, there is available the fact

$$R(a, b) \ \& \ R\,(b, c) \supset R\,(a, c),$$

where a, b, c denote particular objects in the domain. One might then apply two operational rules in succession: first, abstraction plus generalization as before, giving

$$(x)\ (y)\ (z)\ [R(x, y) \ \& \ R\,(y, z) \supset R\,(x, z)];$$

then, asserting the material equivalence of this to $T(R)$, where T is a gratuitously introduced new second-order one-place predicate letter, giving

$$T(R) \equiv (x)\ (y)\ (z)\ [R(x, y) \ \& \ R\,(y, z) \supset R\,(x, z)],$$

R being now a free predicate variable. One has thereby formally created and defined the abstract and most useful concept of transitivity, here denoted by T. This has been done in effect by two kinds of abstraction, first on the individual constants a, b, c, then on the relational constant R.

It is interesing that Pierce (see ref. 5) had long ago suggested that the instinctive structure of human intelligence imposed severe constraints on the admissible hypotheses human beings could make about their experience and that only because of this was the attainment of knowledge by them possible at all. If there are such negative rules, it would be surprising if there were not positive ones too.

Book Reviews

ECONOMIC REASONING

A Theory of Economic History

By J. Hicks. Pp. vii+181. (Clarendon Press: Oxford; Oxford University Press: London, October 1969.) 25*s* boards; 10*s* paper.

UNLIKE the work of his peers, Nicholas Kaldor and Joan Robinson, Sir John Hicks's work has been marked less by sheer originality than by elegance. From wage theory to growth theory, from the theory of demand to public finance, Hicks has produced work which is less a breakthrough than a consolidation of earlier insights. This is a traditional style: Mill and Marshall—and, until the *General Theory*, Keynes—sought to establish their claims to orthodoxy rather than originality, to intellectual power rather than dash.

Yet, unexpectedly, the doyen of English academic economists has produced a book of originality and power which may prove to be not only his greatest contribution to scholarship but the book which establishes his rightful place in intellectual life. Distinguished economists—Marshall, Keynes, Dobb—have often made excursions into economic history, to illuminate their theories. Some economic historians, like Cunningham, Clapham and Hobsbawm, have sought to use theory to explain their history. Marx has been of course the exemplar of the marriage of economic theory and history. It is hardly an exaggeration to say that there is some of Marx's intellectual strength and adventure in Hicks's latest book, though, if this slightly absurd comparison were to be drawn, it could be said that what it lacks is implicit in its essay-form, the deep grasp of detail.

The problem is a simple one. What is the economic process, historically? According to Hicks, man did not start in primitive simplicity, but in societies dominated by custom, and subject to command by a king or an army chieftain.

From this simple but well-argued point, he goes on to the development of taxation and of a bureaucracy to ensure the payment of taxation. Public finance, therefore, takes precedence over trade. "Their central economic nexus is revenue", he writes of early societies. The market grows up alongside the religious festivals or other gatherings, first with general traders who increasingly specialize. The mercantile economy develops within the protective embrace of the command and customary economies, but it becomes itself a source of conflict between different societies. Hicks sees the city state as the peculiarity which divides Asian history from European history; and it is the relation of the merchants to the cities that he sees to be crucial, because the merchants can help to evolve legal forms that are especially suitable to their own form of trading, and so allow all-round advantages to grow from wider trade.

Beyond this, the development of money, law and credit evolved from city states which coalesced into a semi-mercantilized state. In his discussion of money, Hicks achieves his first act of sheer intellectual brilliance—he uses contemporary monetary theory with a power that illuminates the origins of money in a way that earlier attempts (notably D. H. Robertson's by no means negligible contribution in *Money*) did not.

The fact that he does so in simple non-technical language, and largely omits what he thinks to be incorrect (without refuting it), may mask his achievement. Similarly with his exposition of modern capital theory (pages 148–154), which is a miracle of compression.

This book, like Joan Robinson's *Economic Philosophy*, has much to give the specialist. It also has much to give the non-specialist who wishes to gain an insight into economic reasoning.

JOHN VAIZEY

RISE OF THE SPINNING MACHINE

The Textile Industry

An Account of the Early Inventions of Spinning, Weaving and Knitting Machines. By W. English. (Industrial Archaeology, Vol. 4.) Pp. xiv+242+32 plates. (Longmans: London, December 1969.) 55*s*.

THIS book is one of a series on industrial archaeology prepared under the general editorship of Mr L. T. C. Rolt. It is an account of some of the early developments in spinning, weaving and knitting machines and is a useful addition to the already considerable literature on the subject. The author has successfully presented a great deal of detailed technical information in a readable way and has linked this with interesting observations on the inventors of the early machines and on the times in which they lived.

The fascinating story of invention for the textile industry is told clearly and is well illustrated, so that those who are not familiar with textile machines can readily appreciate the significance of each new development. An extremely wide range of topics is considered. There are, for example, chapters on hand spinning wheels, early carding machines, the spinning machines of Arkwright and of Paul, Hargreaves's spinning jenny, Roberts's automatic mule, Kay's fly shuttle, Cartwright's loom, Lee's stocking frame, and developments in pattern weaving. There are also essays on the rise of the woollen and worsted industries and of the flax industries, and the book includes two chapters on the factory system. In other chapters, more recent progress in spinning, weaving and knitting machines is briefly considered.

On reading the book it is impossible not to be impressed by the great tradition of the textile industry. Men of widely different backgrounds contributed to its development. Kay, Hargreaves, Arkwright and Crompton had practical knowledge of the industry and were highly skilled engineers. Dr Edmund Cartwright, however, one of the outstanding inventors, knew nothing about textile processing when he became interested in the problem of weaving. He was educated at New College, Oxford, and was awarded the degree of Doctor of Divinity in 1806. At the age of 41 when he was rector of Goadby Marwood, he happened to discuss with some Manchester businessmen the possibility of constructing a loom which could be driven by water or steam power. The general opinion of manufacturers of the day was that the construction of such a loom was almost impossible. Although he knew nothing about the subject, "having never at the time seen a person weave", Cartwright decided to disprove the argument. In this he was successful and in due course he patented satisfactory machines.

In an industry which has so successfully exploited human ingenuity, it is inconceivable that it should now become stagnant and unprogressive. The contemporary textile industry is still a fruitful field for the inventor, who is now generally a sophisticated engineer or an applied scientist, and as the author of this book says in his concluding paragraph, "the future of the textile industry appears as a vision of more new raw materials, of spinning without spindles, weaving without shuttles and knitting without needles".

Mr English has presented his material well. It is well documented, there is a good bibliography and the book will give great pleasure to all who are interested in the origins of today's highly industrialized society.

C. S. WHEWELL

TOWN BLIGHT

Urban Decay

An Analysis and a Policy. By Franklin Medhurst and J. Parry Lewis, with a chapter by Elizabeth Gittus. Pp. xvi + 174. (Macmillan: London, October 1969.) 65*s*.

THE problem of urban decay is undoubtedly one of the most urgent facing planners today. It is estimated that in 1961 between 2·5 and 3·5 million houses in England and Wales were in need of some kind of renewal, and that by 1981 another million houses will have been added to these. In spite of the apparent success of some local renewal projects, planners are still basically undecided about the best way of handling the existing problem, and seem to have little idea about what ought to be done to make sure that urban decay is less of a problem in the future. The main reason for this seems to be that not enough is known about the conditions of decay, nor about the complex processes involved. Hence it is unfortunate that the authors of this slim volume cannot be considered to have made more than a superficial contribution to solving the problem.

The empirical analyses reported in the book are unimpressive and somewhat disappointing. They add little to our knowledge of the conditions of decay and, regrettably, do not yield any new insights into the complex processes at work. This may be because the studies seem to have been ill-conceived, in part because of the rather naive level of quantitative analysis that was used. This is particularly true of the attempts made to index the level of physical and environmental decay, and although the analysis of change in part of Manchester's twilight area is interesting, the details which are provided could have been put to better use. Instead, these details are used to suggest hypotheses which seem to form the basis of on-going research into the broader aspects of urban change presented at length in chapter five. It is a great pity that the discussion is in terms of what might be done rather than what has been done.

The book is, nevertheless, not without its good parts, and for me these include the short but excellent review of the sociological aspects of urban decay contributed by Elizabeth Gittus and the attempts made by the authors in the last chapter to formulate a policy towards decay. Here it is sensibly argued that greater effort should be made to repair decaying property rather than to demolish it, and a number of suggestions are made whereby the costs of repair could be reduced and the benefits to property owners increased. The authors stress, moreover, that any policy towards decay must be contained in a larger urban policy set within the broader framework of policies for regional development. BARRY J. GARNER

SOPHISTICATED AERIALS

Radiotelescopes

By W. N. Christiansen and J. A. Högbom. (Cambridge Monographs on Physics.) Pp. x + 231. (Cambridge University Press: London, September 1969.) 90*s*; $14.50.

TWENTY-FIVE years ago a radio telescope was just an aerial, but today there are many sophisticated and elegant systems which bear little resemblance to Grote Reber's original telescope and which can extract and use the information in the incoming waves more efficiently than the classical parabolic reflector. The authors of this book, Christiansen and Högbom, have for many years been associated with the design of unusual radio telescope systems. Christiansen's grating telescope was used in very early studies of the radio sun and, when it was later multiplied with an orthogonal grating, the language of the art was enriched by the colourful "chris-cross". One would expect a book of quality from these authors and, indeed, one is not disappointed. It is aimed at the graduate or near-graduate level and will satisfy a demand for a reliable and almost complete reference work on the subject.

It is almost complete. One would not fault it because it could not include all the tricks of the trade. Nevertheless, one could not recommend it as the only reference work on radio telescopes to a class of budding radio astronomers. It would have to be garnished with a subsidiary work on aerials and practical tips. In the index and in the text, one looks in vain for Yagis, helices and all sorts of little facts and details that build up to the sophisticated systems that appear in the two hundred and twenty well printed pages. They are not to be found. How does one obtain circular polarization ? How does one methodically taper an extended aerial without tears and sweat, and what steps should be taken to maintain coaxial feeders constant on extended phased systems ? Chapter 6 tells one the facts about feeder attenuation that may be gleaned directly from the manufacturers' literature; it tells one that the beam may be steered by varying the phase, but it omits the associated problems of phase stability, though these problems were first tackled and solved by radio astronomers. Finally, a minor point of presentation: it would have been much easier to navigate from the "contents" sheet to the relevant pages if the page numbers had appeared in the contents.

These minor criticisms only represent the greed of the reviewer who would have liked to have had a little more for his money, but who would nevertheless strongly recommend this little book to all radio astronomers, whether budding or fully fledged. It should also form part of the library not only of every department of astronomy, physics and electronics, but also all other sciences where these principles may yet find application.

R. C. JENNISON

MODERN METEOROLOGY

Essentials of Meteorology

By D. H. McIntosh and A. S. Thom. (The Wykeham Science Series for Schools and Universities.) Pp. xv + 238. (Wykeham: London and Winchester, 1969.) 20*s*.

THE teaching of meteorology in schools is usually undertaken by the geography master, with the result that students retain an impression of a collection of maps and statistics with little physical content. Some meteorologists believe that this leads to difficulties in attracting suitable workers to the field. Accordingly, they will welcome this admirable book by two staff members of the University of Edinburgh for its thoroughly scientific treatment of present meteorological knowledge at a level attainable in the upper forms of schools or early years of university.

The reader is introduced in considerable detail to almost all topics of interest to modern meteorology, a range too great to list here. Broadly, however, basic physical laws, such as Newton's laws of motion and the gas laws, are cast into a form applicable to the elements. The reader will learn how atmospheric scientists picture weather phenomena from dust devils to cyclones and how they are observed, how the energy of these motions is replenished from the Sun and lost again to space, how their behaviour may be forecast and why such forecasts are expected to improve.

There are already available several texts which are intended as introductions to meteorology for enthusiastic sixth formers. The distinctive feature of this book is the unflinching use of mathematics, permitting brief and precise arguments and affording a more accurate and comprehensive feeling for the subject. In places, the student is confronted with partial derivatives, vectors and laplacians. He will not be familiar with such notation, and, although its meaning is explained as it is introduced, some difficulty must be anticipated. (For this reason the misprint in the first use of vector notation on page 91 is regrettable.) Mathematical complexity reaches its height in the account of computer-based forecasting where key new ideas are introduced almost line by line with baffling brevity. No links are actually missing, however, and the tenacious will be rewarded. Let reluctant mathematicians be undeterred by that warning; they will find much which is interesting and succinctly explained. Some chapters, for example those on rain processes and on methods of observation, require no mathematics at all, and others require very little. Physics teachers may extract from these a fund of illustrations, useful to the lower school.

The style is rather disjointed and I was distracted by the number of footnotes and references to sections later in the book, but the attractive finish, the wealth and authority of the information and the reasonable price more than compensate.

R. S. Harwood

SOUTHERN AFRICAN GEOLOGY

Geological History of Southern Africa

By S. H. Haughton. Pp. 535 + 16 plates. (The Geological Society of South Africa: Johannesburg, 1969.) R10.50.

Southern Africa is of exceptional geological interest, as well as of immense economic importance on account of its mineral resources. For an account of the geology of this region one formerly referred to the *Geology of South Africa* by A. L. du Toit, which is one of the best books on regional geology ever written. Dr Haughton revised the third edition, which was published in 1954, but, since then, so much new work has been carried out that a completely new book became necessary. Nobody is better qualified to evaluate the formidable mass of geological data relating to Southern Africa than Haughton, who has been in the forefront of South African geology for more than half a century. He has written a careful, judicially balanced and authoritative account, which will serve as a standard reference on the geology of southern Africa for many years.

One inevitably compares the new book with du Toit's masterpiece. Haughton is less successful. His arrangement, partly chronological, partly geographical, is confusing. Regional correlation tables, with ages, would have helped the reader, and more maps and diagrams are needed (some of those used are poor). Too much attention is paid to stratigraphic nomenclature and too little to fundamental problems. One looks in a new book on the geology of southern Africa for an up to date account of some of the geological wonders of that region. There are the very old rocks of the Barberton mountainland which are being taken as a model for the earliest stages in the formation of continental crust; the great dyke of Rhodesia and the Bushveld complex of the Transvaal are two enormous bodies of basic igneous rock in which the separation of layers of crystals has produced remarkable mineral concentrations. Around Kimberley and elsewhere there are pipes which contain not only diamonds but also samples carried up from the upper mantle. The Vredefort dome, surrounded by a radial array of shatter cones, has been interpreted as a huge meteorite impact structure. There are fascinating problems connected with the concentration of gold and uranium in the Witwatersrand conglomerate beds. The Dwyka glaciation of southern Africa in the Carboniferous period was for long the most important evidence for continental drift. The Karroo vertebrates on which Haughton is an authority, and the australopithecines from the cave deposits in the Transvaal, are of outstanding interest. Haughton, in this book, does not succeed in leading the reader to appreciate the interest and significance of these and other such phenomena, nor does he provide a clear view of the present state of knowledge regarding them. Much of this new knowledge depends on geophysical and to some extent geochemical work to which Haughton pays too little attention. For example, the palaeomagnetic evidence which tells us about the latitude and orientation of the southern African continent through geological time is almost ignored. Radiometric age determinations are treated rather as though they were an innovation of still doubtful value.

The coloured geological map of southern Africa on a scale of 1 : 5,000,000 is much clearer than the corresponding map in du Toit's book, besides containing a great deal of new detail. The price of the book is low; it is a good buy.

R. M. Shackleton

PLASMA THEORY AND OBSERVATION

Plasma Waves in Space and in the Laboratory

Vol. 1. Edited by J. O. Thomas and B. J. Landmark. (Proceedings of NATO Advanced Study Institute, Røros, Norway, 17–26 April 1968.) Pp. 487. (Edinburgh University Press: Edinburgh, September 1969.) 160*s*.

This volume, the first of two reporting on the Røros school, is composed of more than twenty papers, of a basic introductory or review nature (rather than current research, scheduled for volume two). The topics range widely to cover theory of probes, observations in the laboratory, in the ionosphere and in interplanetary space and theory of plasma resonances and VLF emissions—that is, "space" plasmas in the local, accessible and non-astrophysical sense. In a short review, it is impossible to comment on the papers individually: however, common to many of the contributions is an emphasis on squaring theory with observation. This is meeting with increasing success as is particularly evident in Crawford's discussion of wave propagation in stable laboratory plasmas, and in studies with ionospheric probes (Balmain and Otsiutik). The importance, for the advancement of plasma science, of space plasma as an experimental medium is brought up in a very readable introductory paper on ionospheric resonances (Thomas and Andrews)—free from boundaries, the plasma has relative uniform density, is fully ionized and virtually collisionless. With the development of resonance techniques and probe systems (cf. Storey, Aubry and Meyer on their quadripole probe), sophisticated experiments on natural plasmas are becoming a reality.

The blurb on the dust-jacket claims a role as an up to date textbook, but apart from very few sections—notably the illuminating "Rowlands" theory of plasma waves—the book reports completed work rather than useful approaches. Problems of non-linear waves and turbulence are hardly touched on. Moreover, in trying to be a textbook in excluding both abstracts and conference discussion, the book loses potential usefulness. Comments on the significance and validity of a piece of work—that important and unique contribution of a conference—are lost.

On the other hand, I would congratulate the editors and publishers in producing an attractive, high quality book. There are few printing errors, except in the paper on pitch-angle instabilities, where misprints and poor format are annoying. An error of more substance occurs in Frederick and Scarf's paper on cyclotron modes, where the substitution of β_+ for β_- in equation (14) ignores one region of validity of the classical Bernstein modes. Plasma physicists of diverse interests will indeed find this volume both interesting and useful in cross-fertilizing our fast-diverging studies of plasmas, but its importance as a student text can be only minor.

M. K. Wallis

LIE GROUPS

Lectures on Lie Groups

By J. Frank Adams. (Mathematics Lecture Note Series.) Pp. xii + 182. (W. A. Benjamin: New York and Amsterdam, 1969.) n.p.

THE theory of Lie groups occupies a central position in modern mathematics. This theory is of interest to workers in such fields as algebraic topology, differential geometry, algebra and functional analysis, in addition to its applications in theoretical physics. Although some good texts on the subject are available, the wide area from which its ideas are drawn make it more difficult to learn than more homogeneous branches of mathematics. This new text by Professor Adams in the Benjamin "Lecture Note Series" will be very useful for mathematicians and research students wishing to acquaint themselves with the subject.

This book is not an exhaustive account, but aims to prove the main results on the representations of compact Lie groups, introducing those concepts which are necessary for this purpose. It is based on a course of lectures addressed primarily to algebraic topologists, but the book will also be useful to workers in other fields. It will be particularly useful as a textbook for a graduate course on Lie groups.

The author's style is concise, and this conciseness gives a pleasing clarity to the text. In some places, however, conciseness is carried to an extreme—particularly in chapter one where not all the definitions are given as clearly as one would wish.

After introducing the basic definitions, the author discusses 1-parameter subgroups and the exponential map. Properties of representation spaces are then discussed, including relations between real, complex and quaternionic representations, and the Peter–Weyl theorem is proved. Maximal tori in compact groups are then considered, and the usual concepts of roots, weights, the Weyl group, the Dynkin diagram and the Stiefel diagram are introduced. The method for finding the fundamental group $\pi_1(G)$ from the Stiefel diagram is described. The connexion between the irreducible complex representations and the weights in the fundamental chamber is proved, and the structure of the representation ring of a compact connected simply connected group is derived. The proofs are complete except for some of the results in the early chapters, where references are given instead. There are frequent examples in the text for the classical unitary, symplectic and orthogonal groups.

R. W. CARTER

SYNTHETIC ANTIBIOTICS

Synthesis of Penicillin, Cephalosporin C and Analogs

By Maghar S. Manhas and Ajay K. Bose. (New Directions in Organic Chemistry: A Series of Monographs based on Lectures and Seminars at Stevens Institute of Technology.) Pp. xii + 118. (Dekker: New York, October 1969.) $8.75.

Two discoveries made at the turn of the last decade have led during the past ten years to the introduction of a wide range of β-lactam antibiotics into clinical medicine. The discovery by the Beecham Group that 6-aminopenicillanic acid could be obtained by fermentation enabled thousands of semi-synthetic penicillins to be prepared. The second discovery made by Abraham and Newton was that cephalosporin C was a β-lactam antibiotic which was not destroyed by penicillinases and was effective over a much wider antibacterial spectrum than the penicillins. In this book, Dr Manhas and Professor Bose review developments in this area, which have chiefly occurred during the past ten to fifteen years.

After a short introductory chapter, the use of physical methods is discussed. It is surprising, however, that while all the chief methods are presented, including recent applications of the nuclear Overhauser effect, the authors fail to mention the very interesting ultraviolet absorption spectra of the cephalosporins.

Chapters 3 and 4 constitute the major part of the book and are concerned with the synthesis of the penicillins and cephalosporins and their analogues respectively. These chapters provide a useful summary of the literature although the authors have perhaps given undue space to their own synthetic contributions. One of the most interesting features of cephalosporin chemistry has, however, been neglected. This concerns the unusual facility with which the allylic acetoxy-group is substituted by nitrogen and sulphur nucleophiles in aqueous medium. This type of substitution, first noticed by Abraham and Newton, has been extensively studied by the Glaxo group.

The mode of antibacterial action of the penicillins is now very largely understood at the molecular level, largely because of the work of Strominger and his collaborators. It is surprising that this work is mentioned only very briefly and the conclusions regarding the essential molecular features for antibacterial activity are ignored. These conclusions allow a rational approach for future synthetic endeavours which the authors anticipate.

The text contains very few errors. Structural formulae are clearly presented and liberally used. The occasional omissions and mistakes in formulae are generally irritating rather than misleading. The literature is surveyed to July 1969.

G. LOWE

LABORATORY TECHNIQUES

Electrophoresis of Proteins in Polyacrylamide and Starch Cells

By A. H. Gordon. Pp. 149. Hfl.15; 35*s*.

An Introduction to Gel Chromatography

By L. Fischer. Pp. 246. Hfl.25; 58*s*.

Immunochemical Techniques for the Identification and Estimation of Macromolecules

By J. Clausen. Pp. 175. Hfl.15; 35*s*.

(Laboratory Techniques in Biochemistry and Molecular Biology, edited by T. S. Work and E. Work.) (North-Holland: Amsterdam and London, 1969.)

THESE books are paperback editions of the three parts which make up volume one of a series "Laboratory Techniques in Biochemistry and Molecular Biology" edited by T. S. Work and E. Work. Thus the research worker can acquire an individual text on the technique of most interest to him rather than purchase the complete volume which presumably will be principally destined for departmental libraries. All three volumes set out to give expert practical advice and are intended for readers with little or no previous experience of the techniques discussed. This aim is satisfactorily achieved by all three authors, who adopt a similar approach: a brief outline of the basic principles followed by a detailed account of the methods, apparatus and practical applications.

The first book is devoted to gel electrophoresis using both polyacrylamide and starch supports. The author describes lucidly the advantages and disadvantages of both materials as applied to various problems. He discusses clearly the preparation of the gels, the choice of a suitable apparatus and the detection and recovery of separated material, and he provides a very useful appendix of buffer solutions.

The second book is an introduction to gel chromatography, and the author describes the preparation of the gel, the choice of a suitable column and the various elution techniques. The many practical applications mainly involve the use of 'Sephadex', but this is probably not due to any loyalties of the author to his employer, Pharmacia Fine Chemicals AB, the manufacturers of 'Sephadex', but is merely a reflexion of the domination of the market by this product. Although any reference work on biochemical techniques must contain a chapter on gel chromatography, this book, which is the most expensive of the trio, must be considered a poor investment because it contains little more information than can be obtained from the technical literature provided free by the manufacturers of these materials.

The third book describes the uses of immunochemistry for the identification of various macromolecules, for example, polysaccharides, proteins and lipids. The author follows the pattern set by the other two books and concentrates upon the practical applications of the technique and, in particular, pointing out to the reader the possible errors and misinterpretations which can arise. It is pleasantly free from the bewildering terminology which many authors in this field use with reckless abandon and which may have previously discouraged potential users of this valuable technique.

All three books are printed on good quality paper; they are easy to read and should stand up reasonably well to the constant handling a laboratory manual will inevitably receive. The title on the spine of my volume on immunochemistry contained a glaring error—'macromoleculse'.

N. SHAW

CONSTITUENTS OF LICHENS

Chemical and Botanical Guide to Lichen Products

By Chicita F. Culberson. Pp. xi+628. (University of North Carolina Press: Chapel Hill, November 1969.) $12.50.

THIS is a good book which will probably be the standard text on the subject for some time to come. Lichens produce a wide range of compounds which have been variously called lichen acids, lichen substances or lichen products. They include depsides, depsidones, dibenzofurans, usnic acids, chromones, xanthones, anthraquinones, carotenes, sterols, terpenes, terphenylquinones and pulvinic acid derivatives. Many of these compounds are known only from lichens, particularly those which are acetate-polymalonate derived aromatic phenols joined by esterification, oxidative coupling or both.

Two quite different groups of scientists are interested in these compounds. First, and for obvious reasons, there are organic chemists. Second, there are lichen taxonomists. It is over a century since Nylander described the "colour tests" which became an integral part of the identification and classification of lichens. In recent decades, the development of simple microchemical methods for the identification of specific compounds has had a major impact on lichen taxonomy. Indeed, in the taxonomy of no other group of plants has chemistry been used so successfully as in lichens.

This book is good because it caters so well for both the chemist and the lichen taxonomist. Dr Culberson herself is an organic chemist with an eminently well deserved reputation in the chemistry of lichen products. She has been closely associated in her work with her husband, a lichenologist who is the leading expert in the world in the chemical taxonomy of lichens. Hence, the lichen nomenclature in this book is modern and reliable, with the synonymy thoroughly checked.

The essential core of the book consists of two major reference sections. The first lists more than 300 chemical constituents of lichens, with physical data, chemical structures and annotated references. The second lists the occurrence of these compounds in approximately 2,000 species, forms and varieties of lichens. There is also an excellent chapter on the biogenesis of lichen products and their relationship to the products of free-living fungi. In dealing with the chemical constituents, the author has not restricted herself to secondary products or lichen acids, but she also includes carbohydrates, amino-acids, vitamins and growth factors.

Some lichen taxonomists might have appreciated an introductory guide to the actual methods of using microchemical techniques, although copious references on them are given. Likewise, the chemist might have been given some guide as to what compounds might be expected in previously unstudied lichens, especially where primary metabolites are concerned.

Perhaps the most important comment I can make, however, is an earnest wish that the author and publishers will be able to produce new editions of this book when advances in research make this necessary.

D. C. SMITH

GROWING VASCULAR CELLS

Tissue Cultures

By O. J. Pollak. (Monographs on Atherosclerosis, Vol. 1.) Pp. xii+143. (Karger: Basle and New York, 1969.) SFr./DM 41; 82*s*.

A MONOGRAPH on tissue culture might seem to be an unusual start for a series devoted to atherosclerosis. Workers in the field will, however, appreciate the need for a fundamental study of the prime reactor in the atherosclerotic process, namely, the vascular endothelial cell.

The book is comprehensive and has a full bibliography. It emphasizes and summarizes the many difficult problems encountered when carrying out and interpreting experiments with growing vascular cells. Not the least of these problems is the precise identity of the cell that emerges in the course of tissue culture; a problem that is still not entirely solved. A more intensive cytochemical study of such cells might be of value in establishing cell identity; the author discusses and emphasizes cytochemical techniques as applied to tissue culture.

Much of the work that is described is concerned with aortic endothelial cells. It does not necessarily follow that they resemble the lining cells of coronary arteries that have not been so fully studied. This important point is made, but perhaps not forcibly enough.

The end of the book is better than the beginning. Towards the end there is more discussion and critical comment. The beginning is more of a list of results and names of authors with little or no commentary on the quality or significance of the reported works.

It is sometimes difficult to understand the meaning of sentences largely because of the American use of English, but generally speaking the subject is clearly and concisely expressed.

This book provides a rare, valuable summary of modern work on arterial cell culture and is an important addition to the writings about atherogenesis. G. A. GRESHAM

Obituaries

Dr G. D. Greville

GUY D. GREVILLE, who died on December 13, 1969, at the age of 62, had been head of the Department of Biochemistry at the Agricultural Research Council Institute of Animal Physiology, Babraham, Cambridge, where he succeeded Sir Rudolph Peters in 1959. After graduating with a double first in chemistry at Cambridge in 1929, he worked for some years in the biochemical section of the Middlesex Hospital Medical School, where he collaborated with F. Dickens and E. C. Dodds. In 1937 he was appointed research biochemist in charge of the biochemical laboratories at Runwell Hospital, Essex, and in 1944 joined the Ministry of Supply team, headed by Dr M. Dixon, working at Cambridge on the actions of war gases on enzymes. When the team was disbanded, he was appointed to a lectureship in the Department of Biochemistry at the University of Cambridge and continued there until the move to Babraham in 1959.

Greville's main contributions were in the field of mitochondrial metabolism and the action of "uncoupling" drugs. His first biochemical studies were carried out in collaboration with F. Dickens and dealt with sugar conversions and breakdown in embryonic, tumour and adult normal tissues. In 1933 he began, with E. C. Dodds, an investigation of the metabolic stimulation produced by dinitrophenol, and that led on to a study of "uncoupling" drugs that formed the subject of his PhD thesis and became an interest that continued throughout the rest of his life. In the early 1950s improved methods made possible the preparation of mitochondria and more direct investigation of their metabolic activities. In collaboration with A. L. Lehninger, Greville showed that both D and L-β-hydroxybutyrate undergo oxidation in mitochondria although the L-isomer was thought to be the "naturally occurring" form. The initial paths of oxidation of the two forms were found to be different, but it seemed that the D-form also occurred naturally and played a part in ketone body and fatty acid metabolism.

In 1955 Greville and D. M. Needham showed that dinitrophenol accelerates the ATPase activity of both myosin and mitochondria and, from 1956, Greville began a collaboration with J. B. Chappell on mitochondrial swelling. They established that the swelling induced by a variety of agents, for example phosphate, thyroxine and calcium ions, was dependent on respiration and a supply of energy. After moving to Babraham in 1959, Greville continued to work on the biochemistry and morphology of mitochondria. Important studies were made of the influence of the composition of the suspending medium on the properties of these organelles and the mechanism by which they accumulate divalent metal ions. In collaboration with E. A. Munn, he isolated a new protein, for which the name calliphorin has been proposed, from mitochondria of the flight muscles of *Calliphora erythracephala*. Calliphorin has been purified to a single component and, together with related proteins, seems to be an important storage substance fairly widely distributed among the insect orders.

Everyone who has known or worked with Greville pays tribute to the immense care and patience he exercised in his experimental work and the meticulous repetition used to ensure the accuracy of his observations. He spent a large part of his time helping other people with their research work, but was so self-effacing that many of these contributions went unacknowledged. His long experience and critical attitude made him an invaluable source of information and in recent years he wrote many noteworthy reviews on mitochondrial biochemistry. An endeavour to which he recently devoted much time and care has been his co-editorship with P. N. Campbell of *Essays in Biochemistry* on behalf of the Biochemical Society. Authors contributing essays have been somewhat staggered to find that the Editor had checked every reference in lists frequently running to several hundred. At the time of his death, Greville was actively working on the sixth volume of this immensely successful series which is widely read for both pleasure and profit by advanced students and established workers in biochemistry.

Greville worked in a field in which there has been much controversy and moved among workers between whom deep and sometimes bitter disagreements had arisen. His balanced viewpoint here was highly regarded throughout the scientific world. It is characteristic of his modesty and humour that when asked to scrutinize Mitchell's chemiosmotic hypothesis of respiratory chain and photosynthetic phosphorylation he introduced this as follows: "The present writer when asked for a bird's eye appraisal of the Mitchell hypothesis felt that the wrong phylum had been selected, and he offers instead a worm's eye scrutiny. His chief qualifications are that he is completely uncommitted and likely to be psychologically satisfactory, since he is on excellent terms with those of the protagonists whom he happens to know."

Dr I. A. Galloway

IAN GALLOWAY, director of the Animal Virus Research Institute at Pirbright in Surrey from 1939 to 1963, died suddenly on December 22, 1969. He had been the leading figure in foot and mouth disease research in Britain for many years and was responsible for the major development of the laboratory at Pirbright and for the research programme which has given it its high international reputation in the field of foot and mouth disease.

Galloway was born in Edinburgh in 1900 and educated at George Heriot's School and the Royal (Dick) School of Veterinary Studies, obtaining his membership of the Royal College of Veterinary Surgeons in 1922 and his BSc the following year. His early training in research was at the Institut Pasteur, where he entered the service of Professor Levaditi. Galloway returned to England in 1926 to work at the National Institute for Medical Research at Hampstead on behalf of the Foot and Mouth Disease Research Committee. He was at Hampstead until 1939, when it was decided to appoint a scientific superintendent to the research station operated by the committee at Pirbright. Galloway remained at Pirbright for twenty-four years, during which he transformed the research station from a small field unit into a well equipped institute for virological research.

Galloway's contribution must be seen against the enormous changes in virological research which occurred during his career. In the early 1920s much effort was devoted to the search for experimental animals to avoid expensive experimentation in the natural hosts. Galloway's first publication recorded the pathogenicity of foot and mouth disease virus for the rabbit, a host which, although susceptible, was never destined to supplant the guinea-pig in this field. In Paris Galloway had become interested in the problem of the size and physical characteristics of the virus; at Hampstead he and W. A. J. Elford began studies of virus size based on ultrafiltration analysis and later on ultracentrifugation. Their findings, which gave values of 8–12 nm by filtration and 20 nm by centrifugation, were not widely different from those determined twenty or more years later by more refined techniques.

The facilities at Pirbright in 1939 were a challenge to Galloway, allowing him to scale up his work and make use of the farm animal instead of the guinea-pig. He insisted that, if results of value were to be obtained (for example) in vaccination experiments, adequate numbers of cattle should be employed to give statistically significant results and, stimulated by him, methods for accurate assay of the virus and for the estimation of immunogenic potency of vaccines were developed during the 1940s. Comparison of vaccines of different strains within one general immunological type brought to light hitherto unsuspected differences. Papers from the institute published in 1949 showed the importance of subtype differences in immunization programmes, and this work has influenced the practical application of foot and mouth disease vaccines all over the world.

By his personal contacts overseas, Galloway stimulated an interest in dealing with foot and mouth disease in underdeveloped countries, first of all by surveying the strains of virus that were present. This work led to the discovery of three new types in Africa in the late 1940s and a further type in Asia in 1955. The survey work established by Galloway became so obviously valuable that its continuance was guaranteed by the establishment at

Pirbright of the World Reference Laboratory for Foot and Mouth Disease in 1957.

Under his direction in the 1950s the institute developed many new techniques, notably in tissue culture, and Galloway was able to encourage the development of more advanced work in the biochemistry and biophysics of the virus which he himself had been associated with twenty years earlier, with Elford.

Galloway took a leading part in much international discussion on the control of foot and mouth disease. He advised the US Government in 1946–47 on the campaign against the outbreak in Mexico and was responsible for founding the Technical Group of the European Commission for the Control of Foot and Mouth Disease. Through these international activities it can be fairly claimed that he helped greatly towards the cooperation which has achieved a reduction of the disease in many of the most seriously affected areas.

He is survived by his wife, one son and two daughters.

Correspondence

Sternglass's Assumptions

SIR,—The letter under the above title by P. L. Taylor (*Nature*, **225**, 881; 1970) is an example of arguing in a circle. He proves that infant mortality is an exponential function of time by making the assumption that the overall fractional rate of change is constant !

As we have stated in our paper (*Nature*, **224**, 1257; 1969), there is no justification for such an assumption. Even if we postulated an exponential dependence for each individual cause of death, it would not be true for the total mortality, since the different causes of infant mortality are reduced at different rates. Indeed, there is at least one cause, due to genetic defects, which is either irreducible or can only be reduced extremely slowly. Thus a plot of the logarithm of total mortality against time would give a curve with a gradually decreasing slope and not a straight line.

Yours faithfully,

PATRICIA J. LINDOP
J. ROTBLAT

The Medical College of St Bartholomew's Hospital,
Charterhouse Square, London EC1.

Information Explosion

SIR,—I hope that the scientific community will heed Professor Webb's warning (*Nature*, **225**, 132; 1970) that we need new ways of presenting information if we are to survive the crisis brought about by the growth of the published literature.

Our colossal indifference to this basic problem stems perhaps from our belief that we can solve it by using computers. Yet this approach is obviously hopeless. Machines can retrieve information for the reader, but they cannot assimilate it for him.

If we examine the literature, we see that it is designed to save publishing costs and not to aid the reader in rapidly and easily comprehending complex information. What fundamentally we need to do then is (1) recognize that the cost of publication is an integral part of the cost of research and be prepared to pay adequate page costs and (2) redesign the literature for rapid reading and easy assimilation.

Although this program will raise the cost of publication by about 10 per cent, this increased cost will be offset by the manifold greater economic returns resulting from the increased usefulness of the information being published.

Yours faithfully,

F. BRUCE SANFORD

US Bureau of Commercial Fisheries,
Division of Publications,
Seattle, Washington 98101, USA.

Keep Off the Grass

SIR,—As mentioned in your leading article[1] of February 7, 1970, more research is needed on cannabis, the effects of which have often been compared with those of alcohol. But a present obstacle against undertaking these highly desirable researches is the great difference between the problems of excessive alcohol consumption and those of the illegal consumption of marihuana, hashish or other cannabis products. The difference is that results obtained from biochemical, pharmacological or behavioural studies of alcohol can be correlated with the amount of alcohol circulating in the individuals under test (a good number of reliable methods of assay are available), whereas none of the results, even those of recent date[2-4], can be linked with the tetrahydrocannabinols (THC), either as such or metabolized and present in the experimental subjects. This present lack of a quantitatively reliable assay of the amount of active principle or principles of cannabis, absorbed and maybe circulating in the blood or perhaps in other body fluids, makes an accurate assessment of the pharmacological or behavioural data almost meaningless, especially if such results are compared with the effects of alcohol or other drugs or obtained with control groups. May I express a strong hope that this problem of an analytical method, obviously for micro-quantities, will be solved soon, because without it there is little chance of establishing the true nature (benign or dangerous) of cannabis ?

THC may be transformed into the materials which, in fact, affect the central nervous system, and there are in any case wide individual variations in the subjective and objective effects. Moreover, illegally acquired marihuana cigarettes (as is often ignored) are usually low in their contents of active constituents, and the long-term effects of cannabis on Western man are unknown. All these uncertainties add to the great difficulty of giving unbiased judgment about the kind of harm (temporary or permanent) that abuse of the drug would bring about. This leaves the presence of tobacco, mixed with hemp particles in the pot cigarettes, outside any consideration of damage to health.

One further point merits emphasis: if one takes "harm" as measure of the degree of hardness of a drug, and not the number of habituates or addicts, then the amphetamine and barbiturate groups are surely harder than cannabis. But that alone is no recommendation to free cannabis from its legal shackles. On the contrary, without entering a large list of reasons for this viewpoint, one can only agree with the last sentence of the leader of *The Times*[5], just as one has to agree with your leader, when it places education, information and public discussions at the top of priorities in the struggle against the problem of drug taking, and at the same level as legislation.

Yours faithfully,

F. BERGEL

Magnolia Cottage,

SI Units

SIR,—Much erudite discussion has been initiated by the adoption of SI units by some journals, notably those of the Royal Society. There are plenty of scientists well versed in the strange problems of electromagnetic units and dimensions, but may I as a sometime sailor raise a small squeal of protest at recent horrors perpetrated in the name of SI by *Phil. Trans. Roy. Soc.* on my innocent nautical units.

A ship, everyone knows—even the French—travels at so many knots. An ocean current likewise, since it is usually combined with a ship's speed, is most frequently quoted in knots. There is nothing inherently inferior in knots (of celestial origin), certainly not in comparison with the abomination $m\ s^{-1}$ with which I find my proof besmirched. Ask any sailor from Ordinary Seaman to Admiral of the Fleet to proceed at $2\cdot8\ m\ s^{-1}$ when you mean $5\frac{1}{2}$ knots and the response, though the request come from the Royal Society its very self, is likely to be nautical and brief.

To add insult to injury, the same proof describes the vessel I use as "94 Mg (tonnes) gross". This absurdity is what our SI fiends believe a gross tonnage of 94 is. Perhaps one day some of these megagrammage proponents would care to see how their precious unit is calculated—by taking a tape and measuring up (*inter alia*) the living accommodation on board.

There comes a stage when the SI-ing has to stop. Somebody in the cellars of Carlton House Terrace probably spends all his time taking the scientists' lingua franca and nano-ing and tesla-ing it. When he runs out of papers (and the present policy will soon ensure that), he might start on the classics. Prince Hal's injunction to Falstaff "not to come near my person by ten mile" is ripe for conversion and decimalization.

Yours faithfully,

DAVID DAVIES

Massachusetts 02178.

University News

Dr John Stewart Pate has been appointed to a personal chair in plant physiology in the Department of Botany, **Queen's University of Belfast.**

Dr T. J. Biscow has been appointed to the second chair in physiology, **University of Bristol.**

Dr Joseph E. Murray has been appointed professor of surgery at the Peter Bent Brigham Hospital and the Children's Hospital Medical Center in the Faculty of Medicine, **Harvard University.**

Dr A. M. James, Queen Elizabeth College, London, has been appointed to the chair of physical chemistry, tenable at **Bedford College, London.**

Dr J. K. Sutherland, University of London, has been appointed professor of organic chemistry in the **University of Manchester,** in succession to Professor A. J. Birch.

A research council has been established at the **University of Moncton,** New Brunswick, to plan and coordinate research activities. **Dr Brian T. Newbold** has been appointed president of the council and full time director of research, and the other members of the council are **Dr Auréa Cormier,** School of Home Economics, **Dr Léonard LeBlanc,** Faculty of Science, **Father Jules Léger,** Department of History, **Dr Gaston Allaire,** Department of Music, **Dr Pierre Dion,** Psycho-Social Centre, and **Dr Emmanuel Sajous,** Department of Economics.

Mr Gerald Dix has been appointed to the chair of planning and the directorship of the Institute of Planning Studies in the **University of Nottingham.**

Dr George Eason has been appointed to the new chair of mathematics for applied scientists in the Department of Mathematics, **University of Strathclyde.**

Appointments

Dr Gordon I. Hobday has been appointed managing director of **Boots Pure Drug Company Limited,** in succession to Mr Kenneth Williamson.

Dr F. T. Hamblin, at present chairman and managing director of ICI Deutschland GmbH and of ICI (Switzerland) AG, has been appointed to the new post of director of the **British Plastics Federation.**

Announcements

The **Grand Prix Scientifique de la Ville de Paris** has been awarded to **Professor Lucien Malavard.**

D. P. Rose, University of Bradford, has been awarded the **Sir Walter Puckey Prize** in production engineering, administered by the Institution of Production Engineers.

Dr George H. Mitchell has been awarded the Clough memorial medal of the **Edinburgh Geological Society,** for his contributions to the knowledge of the geology of the Lake District, the West Riding of Yorkshire and the south of Scotland.

The **US National Science Foundation** will provide travel grants for about eighty scientists from the United States to attend the NATO advance study institutes to be held in Europe this summer. Applications should be made to the director of the appropriate institute.

The **Biochemical Society** has made the following awards: **the CIBA medal** to Professor T. W. Goodwin, Liverpool, for his work on the biosynthesis of carotenoids and plant sterols; **the Colworth medal** to Dr George Radda, Oxford, for his study of the role of flavins in biological systems.

The **Van den Berghs nutrition awards**—prizes of £500, £250 and £100—will be presented to the writers of the three best papers on the theme "Getting the Most out of Food". Entrants should be resident in the United Kingdom, and papers should be written in English and should not exceed 5,000 words. Further information can be obtained from Van den Berghs Ltd, Kildare House, Dorset Rise, London EC4.

The **Zoological Society of London** has made the following awards: **the Stanford Raffles Award,** to Mr Rex A. Jubb, Grahamstown, South Africa; the **Scientific Medal,** to Professor R. McN. Alexander, University of Leeds, Dr R. V. Short, University of Cambridge, and Professor T. R. E. Southwood, Imperial College, London; **the Thomas Henry Huxley Award,** to Dr Gillian D. Sewell, King's College, London.

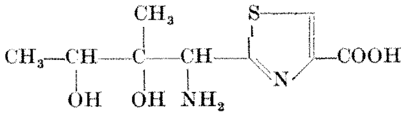
The clean air awards, to be made by the National Society for Clean Air, will now be known as the **Arnold Marsh Clean Air Awards** in memory of Arnold Marsh, director of the society during 1928–68. Contributions to the cause of clean air by individuals, industry and local government authorities are eligible for the awards, which will be made in October. Further details can be obtained from the National Society for Clean Air, Field House, Breams Buildings, London EC4.

The council of the **Institute of Physics and the Physical Society** has made the following awards: **Guthrie medal and prize,** to **Professor A. B. Pippard,** University of Cambridge; **Rutherford medal and prize,** to **Professor S. Devons,** Columbia University; **Glazebrook medal**

and prize, to **Dr E. Eastwood,** English Electric Company; **Maxwell medal and prize,** to **Dr R. J. Eden,** University of Cambridge; **Charles Vernon Boys prize,** to **Dr A. Hewish,** University of Cambridge; **A. B. Wood medal and prize,** to **Dr B. S. McCartney,** National Institute of Oceanography; **Simon memorial prize,** to **Professor W. Meissner,** Bavarian Academy of Sciences.

The council of the **Geological Society of London** has made the following awards: the **Wollaston Medal** to Professor P. Kuenen, Dutch Geological Institute; the **Murchison Medal** to Professor R. M. Shackleton, University of Leeds; the **Lyell Medal** to Professor F. H. Stewart, University of Edinburgh; the proceeds of the **Wollaston Fund** to Dr D. H. Matthews, University of Cambridge; the proceeds of the **Murchison Fund** to Dr A. C. Bishop, British Museum (Natural History); moieties of the **Lyell Fund** to Professor B. M. Funnell, School of Environmental Science, Norwich, Dr R. Goldring, University of Reading, and Mr R. McQuillin, Institute of Geological Sciences.

ERRATUM. The following corrections should be made to the article "The Structure of Thiostrepton" (*Nature*, **225**, 233; 1970): In Table 1, page 234, all minus (−) signs should be replaced by the letter L and plus (+) signs by the letter D; similar corrections should be made in Fig. 2, page 234, and on line 33 of page 235. In Table 1, the chemical formula of thiostreptine is



In ref. 7, the name of the first author is Cross, D. F. W.

ERRATUM. The author of the article "Effects of Histamine on the Toad Spinal Cord" (*Nature*, **225**, 196; 1970) is A. K. Tebēcis.

ERRATUM. In the article "Activity of Various Fractions of Bradykinin Potentiating Factor against Angiotensin I Converting Enzyme" by S. H. Ferreira, L. J. Green, V. A. Alabaster, Y. S. Bakhle and J. R. Vane (*Nature*, **225**, 379; 1970), the abbreviation pGa on line 12 should read PCA (pyrrolidone carboxylic acid).

CORRIGENDUM. The following corrections should be made to the article "Rotational Properties of Neutron Star Models" by J. M. Cohen and A. G. W. Cameron (*Nature*, **224**, 566; 1969). The term Ω^2 inside the square brackets in equation (2) should be deleted. The entries in column 5 of Table 1 should be identical with those in column 4, and the entries in columns 3 and 4 of Table 2 should be replaced by $1{\cdot}805 \times 10^4$ and $4{\cdot}6 \times 10^{-7}$ times the entries in column 4 of Table 1, respectively. The conclusions of the paper are not affected. We thank K. Thorne and J. Hartle for raising questions concerning the validity of equation (2). The discrepancy was due to a copying error.

International Meetings

March 12–13, **High-Resolution Analyses,** Oak Ridge, Tennessee (Charles D. Scott, ORNL, PO Box X, Oak Ridge, Tennessee 37830, USA).

March 13–16, **US National Science Teachers Association Convention,** Cincinnati (NSTA, 1530 Kingshighway Boulevard, St Louis, Missouri 63110, USA).

March 22–25, **American Wildlife and Natural Resources,** Chicago (C. R. Gutermuth, 709 Wire Building, Washington DC 20005, USA).

March 23, **The Wildlife Society Annual Meeting,** Chicago (Fred G. Evenden, Executive Director, Suite S-176, 3900 Wisconsin Avenue NW, Washington DC 20016, USA.)

March 23–24, **503 Meeting of the Biochemical Society,** London (The Biochemical Society, 7 Warwick Court, Holborn, London WC1).

March 23–25, **Biomathematics and Computer Science in the Life Sciences,** Houston (Office of the Dean, University of Texas Graduate School of Biomedical Sciences at Houston, Division of Continuing Education, PO Box 20367, Houston 77025, USA).

March 24–26, **Solid Wastes Management,** Houston (H. Nugent Myrick, University of Houston, Cullen College of Engineering, Department of Civil Engineering, Environmental Science and Engineering Program, 3801 Cullen Boulevard, Houston, Texas 77004, USA).

March 25–27, **Fundamental and Practical Aspects of Pest Management,** Raleigh (Pest Management Conference, Department of Entomology, North Carolina State University, Raleigh, North Carolina, USA).

March 31–April 3, **Great Lakes Research,** Buffalo (Robert A. Sweeney, Great Lakes Laboratory, State University College, 5 Porter Avenue, Buffalo, NY, USA).

April 2–3, **Electrochemistry,** Guildford (Dr D. S. Allam, Department of Chemical Physics, University of Surrey, Guildford, Surrey).

April 3, **Collagen Club Meeting,** Bristol (Dr A. J. Bailey, ARC Meat Research Institute, Langford, Bristol).

April 5–9, **International Association of Gerontology, European Biological Section,** Leeds (IAGEBS Secretariat, Department of Medicine, The General Infirmary, Leeds LS1, 3EX, Yorkshire).

April 7–9, **Impact of Air Pollution on Vegetation,** Toronto (D. A. Thomas, Air Management Branch, Ontario Department of Energy and Resources Management 1 St Clair Avenue West, Toronto, Ontario, Canada).

April 7–10, **Thermophysical Properties of Solids at High Temperatures,** Salford (The Institute of Physics and the Physical Society, 47 Belgrave Square, London SW1).

April 8–9, **Extrapolation to Man,** Bradford (Professor G. D. H. Leach, University of Bradford, Yorkshire).

April 8–10, **The Biochemistry of the Terpenoids,** Liverpool (Dr J. B. Harborne, Botany Department, The University, Reading RG1 5AQ).

April 10–12, **Chemical Aspects of Tribology,** Reading (Education Officer, Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London SW1).

April 10–12, **Institute of Information Scientists Conference,** Reading (Conference Office, Institute of Information Scientists, 5–7 Russia Row, Cheapside, London EC2).

April 12–17, **Annual Meeting of the Federation of American Societies for Experimental Biology,** Atlantic City (Mrs T. C. Heatwole, 5110 West Franklin Street, Richmond, Virginia 23226 USA).

April 13–14, **Polymer Structure and Properties,** Manchester (Registrar, University of Manchester Institute of Science and Technology, Sackville Street, Manchester M60 1QD).

April 13–14, **Combustion Emission: Effects, Measurement and Control,** Leeds (Dr G. Dixon-Lewis, Houldsworth School of Applied Science, The University, Leeds, 2).

April 13–17, **Automotive Drive-Line,** Jersey (J. E. Lonsdale, Automobile Division, Institution of Mechanical Engineers, 1 Birdcage Walk, London, SW1).

April 14–16, **Computer Graphics,** Uxbridge (Mrs R. Gregory, Department of Computer Science, Brunel University, Uxbridge, Middlesex).

April 14–17, **Automatic Test Systems,** Birmingham (The Conference Registrar, Institution of Electronic and Radio Engineers, 8–9 Bedford Square, London, WC1).

April 17–19, **Discoveries in Biological Psychiatry,** Baltimore (Symposium Secretary, Taylor Manor Hospital, Ellicott City, Maryland 21043, USA).

April 21–22, **Organic Photochemistry,** Manchester (Dr M. G. Barlow, Department of Chemistry, University of Manchester Institute of Science and Technology, Sackville Street, Manchester 1).

April 22–24, **Space Congress,** Cocoa Beach (Timothy H. Hanrahan, The Aerospace Corporation, PO Box 4007, Patrick AFB, Florida 32925, USA).

April 27–May 8, **Measurement, Analysis and Control of Noise,** Sheffield (K. H. Sutherland, Industrial Liaison Officer, Department of Mechanical Engineering, University of Sheffield, Mappin Street, Sheffield S1 3JD).

May 4–7, **London Engineering Congress 1970,** London (LECO '70 Press Office, Council of Engineering Institutions, 2 Little Smith Street, London SW1).

May 11–15, **Random Vibration and Random Signal Analysis,** Sheffield (K. H. Sutherland, Industrial Liaison Officer, Department of Mechanical Engineering, University of Sheffield, Mappin Street, Sheffield, S1 3JD).

May 18–19, **Space Applications of Solid State Luminescent Phenomena,** University Park, Pennsylvania (Professor J. N. Weber, Materials Research Laboratory, University Park, Pennsylvania 16802, USA).

May 22–29, **Tenth International Cancer Congress,** Houston (Tenth International Cancer Congress, PO Box 20465, Astrodome Station, Houston, Texas 77025, USA).

May 25–26, **Cholinergic Ligand Interactions,** Buffalo (Dr D. J. Triggle, School of Pharmacy, State University of New York at Buffalo, New York 14214, USA).

June 1–6, **IX International Mineral Processing Congress,** Prague (The Executive Committee, Ore Research Institute, Modřanská 23, Praha 4, Czechoslovakia).

June 2–July 14, **Ecology of Fishes ; Structure and Function of Marine Animals; Marine Microbiology** (Summer Courses), Port Aransas (The Director, The University of Texas Marine Science Institute, Port Aransas, Texas 78373, USA).

June 8–19, **Applied Optics** (Summer School), London (Registrar, Imperial College, London SW7).

June 15–18, **Tissue Culture Association Annual Meeting,** Washington DC (Mr V. P. Perry, American Foundation for Biological Research, 11125 Rockville Pike, Rockville, Maryland 20853, USA).

September 21–25, **Congress of the International Society for Rock Mechanics,** Belgrade (Congress Secretariat, c/o Institute Za Vodoprivredu Jaroslav Cenri, Bulevar Vojvode Misica 43, 43 Belgrade, Yugoslavia).

September 22–24, **The Vitreous State,** Bristol (Secretary, The Faraday Society, 6 Gray's Inn Square, Gray's Inn, London WC1).

September 23–25, **High Energy Physics,** Durham (Institute of Physics and the Physical Society, 47 Belgrave Square, London SW1).

Sabbatical Itinerants

In the hope of providing some practical assistance in the good cause of mobility between laboratories, *Nature* advertises the needs for housing of families about to take up periods of sabbatical leave. To begin with, no charge will be made for advertisements like this. It is hoped that a period of experiment will show what form these advertisements could most usefully take and whether they are effective.

Wanted: In or near Mill Hill, London. Furnished 2 or 3-bedroom house or flat for New Zealand post-doctoral fellow, wife and two children. From June 8, 1970, for 1 year. Please contact A. J. Cunningham, Wallaceville Animal Research Centre, Private Bag, Wellington, New Zealand.

Wanted: Furnished accommodation for chemist, wife and two daughters for mid-July to mid-August, with easy access to Queen Elizabeth College, London. Reasonable terms. Please contact Professor L. Hough, Department of Chemistry, Queen Elizabeth College, London W8.

Wanted: Furnished centrally heated house or flat in vicinity of Glasgow for doctor, wife and three children, from September 1970–June 1971. Please contact Dr John J. Furth, Department of Pathology, University of Pennsylvania, School of Medicine, Philadelphia, Pennsylvania 19104, USA.

Wanted: Furnished accommodation for biochemist, wife and two sons aged 5 and 3 for one year beginning October 1970. Prefer direct public transportation to King's College, London. Please contact Dr D. E. Olins, Biology Division, Oak Ridge National Laboratory, PO Box Y, Oak Ridge, Tennessee 37830, USA.

Vacant: Large furnished home. Please contact Dr D. E. Olins, Biology Division, Oak Ridge National Laboratory, PO Box Y, Oak Ridge, Tennessee 37830, USA.

Wanted: Furnished house or flat with 2 bedrooms for American professor, wife and two boys, aged 9 and 11, near University of Oxford, for 8 months to 1 year beginning August 18, 1970. Please contact Dr Morton M. Weber, chairman, Department of Microbiology, St Louis University School of Medicine, 1402 S. Grand Blvd., St Louis, Missouri 63104, USA.

Wanted: Exchange of modern, well furnished, spacious, 3-bedroom house (and possible use of car) of research physician in Mount Vernon, New York, 15 min from Bronx and 40 min from central Manhattan, for well heated, 1-bedroom, or larger, flat or house close to Sir William Dunn School of Pathology, Oxford. September 1970 through April or May 1971. We have no children nor will we accept family with small children. Rental of either accommodation would also be considered. Also require small flat in Oxford for single female research associate. Please contact Dr Harold P. Klinger, Department of Genetics, Albert Einstein College of Medicine, 1300 Morris Park Avenue, Bronx, NY 10461, USA.

Vacant: House in Cambridge for 12 months from mid-August 1970. Very comfortably furnished, 3 large bedrooms, living room, dining room, breakfast room, kitchen, bathroom and W.C., garage with room above, garden. All necessary appliances, including dishwasher, linen, dishes, etc. On bus route, ten minutes to centre of town. Part time domestic help available. Please contact Dr P. Sykes, University Chemical Laboratory, Lensfield Road, Cambridge CB2 1EW.

British Diary

Monday, March 9

Management by Objectives (6 p.m. discussion) Institution of Mechanical Engineers, at 1 Birdcage Walk, London SW1.

Myrtos: an Early Bronze Age Settlement in Crete (5.45 p.m.) Dr P. Warren, University of London, at the Institute of Archaeology, 31–34 Gordon Square, London WC1.

Training—a Systems Approach (5.30 p.m.) Captain G. Huggett, Institution of Electrical Engineers, at Savoy Place, London WC2.

Tuesday, March 10

Advanced Passenger Train (7 p.m.) Dr S. Jones, Institution of Electrical Engineers; and the Institution of Mechanical Engineers, at Culham Laboratory, Harwell, Didcot, Berks.

Comparative Form and Function of some Intertidal New Zealand Ophiuroids, Dr R. J. Pentreath; **The Development of Branchiopod Crustacea,** Dr D. T. Anderson; Film (5 p.m.) Zoological Society of London, at the Zoological Gardens, Regent's Park, London NW1.

Deformation and Fracture of Soft Materials (2): Mechanics of Foamed Elastic Materials (4.30 p.m.) Professor A. N. Gent, University of London, at Queen Mary College, Mile End Road, London E1.

Lord Hailey: His Contribution to Africa (5.15 p.m.) Sir Frederick Pedler, Royal Society of Arts, Commonwealth Section; and the Royal African Society, at the Royal Society of Arts, John Adam Street, London WC2.

Management Effectiveness for Engineers (6 p.m.) Mr H. Makepeace, Institution of Electronic and Radio Engineers, at 9 Bedford Square, London WC1.

Some Bronze Age, Iron Age and Early Medieval Settlements in the Netherlands (5.45 p.m.) Professor H. T. Waterbolk, University of London, at the Institute of Archaeology, 31–34 Gordon Square, London WC1.

Steam Engines (6 p.m.) Mr R. M. Palmer, Institution of Mechanical Engineers at 1 Birdcage Walk, London SW1.

Wednesday, March 11

A Geochronological Study of the Lewisian of the Laxford Area, North-west Scotland, Dr R. St J. Lambers and Dr J. G. Holland; **The Sgurr Beag Slide—a Major Tectonic Break within the Moinian of the Western Highlands of Scotland,** Mr P. W. G. Tanner (5 p.m.) Geological Society, at Burlington House, Piccadilly, London W1.

Catalytic Analysis (6 p.m.) Mr A. Townshend, Society for Analytical Chemistry, Midlands Section, at the University of Birmingham.

Electron Spin Resonance in Biological Systems (two-day symposium) at the School of Pharmacy, Regional College of Technology, Byrom Street, Liverpool.

Electronic Production in the 1970's (7.30 p.m.) Mr P. Newell, Institution of Electronic and Radio Engineers, at the Bull's Eye, Basildon, Essex.

Electronics in Cars (5.30 p.m.) Mr L. G. Cripps, Institution of Electrical Engineers, at Savoy Place, London WC2.

Food Legislation (6 p.m.) Mr E. Whittle, Mr R. Blanchfield and Mr R. Knight, Society of Chemical Industry, Food Group; The Association of Public Analysts; and the Institute of Food Science and Technology, at the Middlesex Hospital Medical School, London W1.

History of the Communication of Scientific and Technological Ideas—Summary and General Discussion (1 p.m.) Mr. F. Greenaway, Royal Institution, History of Science Discussion Group, at 21 Albemarle Street, London W1.

Immunological Aspects of Malignancy (2 p.m.) Dr G. Hamilton Fairley, University of London, at the Royal Postgraduate Medical School, Du Cane Road, London W12.

Polymer Processing (9.30 a.m. symposium) Institution of Chemical Engineers, at Salford University.

Problems in Colour Measurement (2 p.m.) Dr D. Patterson; **Colour Measuring Instruments** (3.30 p.m.) Colour Group (Great Britain), Northern Section, at the University of Leeds.

Standards and the Introduction of Metrication (7.30 p.m. brains trust) Mr R. W. Jones and Mr P. C. Young, Plastics Institute, at the Polygon Hotel, Southampton.

The Sand and Gravel Industry (3 p.m.) Natural Environment Research Council, at the Institute of Geological Sciences, Exhibition Road, London SW7.

The Spread of Research at The City University (1.10 p.m.) Professor Richard Cox, City University, at the Graduate Business Centre, Gresham College, Basinghall Street, London EC2.

Welded Process Plant (two-day conference) Institution of Mechanical Engineers; and the Welding Institute, at 1 Birdcage Walk, London SW1.

Thursday, March 12

Applications of Oxygen Sensors in Biological and Other Systems (6.30 p.m.) Society for Analytical Chemistry, at the Royal College of Surgeons of England, Lincoln's Inn Fields, London WC2.

Control of Biochemical Pathways (two-day symposium) at Luton College of Technology, Park Square, Luton. Chairman: Professor P. J. Randle.

Materials in Space Flight (7.15 p.m.) Mr N. H. Langton, Institution of Chemical Engineers, at the University of Strathclyde, Glasgow.

Moon Rock (1.15 p.m.) Dr J. Bastin, University of London, at Queen Elizabeth College, 61–67 Campden Hill Road, London W8.

New Developments in Electron Microscopy with special emphasis on their Application in Biology (9.45 a.m., two-day meeting) Royal Society, at 6 Carlton House Terrace, London SW1.

Recent Progress in the Study of Fast Reactions (symposium, 2 p.m.) Chemical Society, at the Royal Institution, Albemarle Street, London W1.

Rough Surfaces as an Aid to Improving Heat Transfer (6 p.m. discussion) Institution of Mechanical Engineers, at 1 Birdcage Walk, London SW1.

The Future of Agricultural Research (2.30 p.m.) Sir Gordon Cox, KBE, FRS, East Malling Research Station, at Withersdane, Wyme College, Ashford, Kent. (Amos Memorial Lecture).

The Harmony of Growth (5.30 p.m.) Dr Elsie Widdowson, University of London, at Senate House, London WC1.

Friday, March 13

Automation of the Design and Production of a Large Digital Computer (5.30 p.m.) Mr C. D. March, Mr G. Haley and Mr D. Adshead, Institution of Electrical Engineers, at Savoy Place, London WC2.

The Photogeneration of Quinones in Solution of Singlet Oxygen Molecules (1 p.m.) Professor D. R. Kearns, Royal Institution, Photochemistry Discussion Group, at 21 Albemarle Street, London W1.

Thermoset Acrylics—What Next and Where? (6.30 p.m.) Mr P. V. Robinson, Oil and Colour Chemists' Association, at the Manchester Literary and Philosophical Society, 36 George Street, Manchester 1.

Understanding the Solar System (9 p.m.) Professor T. Gold, FRS, Royal Institution, at 21 Albemarle Street, London W1.

Wheatstone and the Generator (5.30 p.m.) Mr B. P. Bowers, Institution of Electrical Engineers, at Savoy Place, London WC2.

Saturday, March 14

Pigments and Extenders (10 a.m.) Oil and Colour Chemists' Association, Scottish—Student Group, at St Enoch Hotel, St Enoch Square, Glasgow.

Wild Life for the Future (3.30 p.m.) Mr George Howat, Inner London Education Authority, at the Horniman Museum, London Road, Forest Hill, London SE23.

Monday, March 16

Nutritional Ideas in the Early Nineteenth Century (5.30 p.m.) Miss A. J. O'Hara May, British Society for the History of Science, at the Science Museum, Exhibition Road, London SW7.

Sonar (5.30 p.m.) Mr T. N. Reynolds, Institution of Electrical Engineers, at Savoy Place, London WC2.

The Choice of Industrial Drives up to 100 hp (5.30 p.m. discussion) Institution of Electrical Engineers, at Savoy Place, London WC2.

The Parliamentary and Scientific Committee (5.30 p.m.) Mr Roger Gresham Cooke, MP, Royal Institution, Library Circle, at 21 Albemarle Street, London W1.

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one copy of NATURE each week is:

12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire................................**£14.0.0** each
United States of America........(by air freight)............ **$48** each
Canada..........................(by air freight).......... **$52** each
Elsewhere overseas by surface mail....................**£14.0.0** each
(Charge for delivery by air mail on application)
Shorter periods *pro rata*. (Minimum three months.)

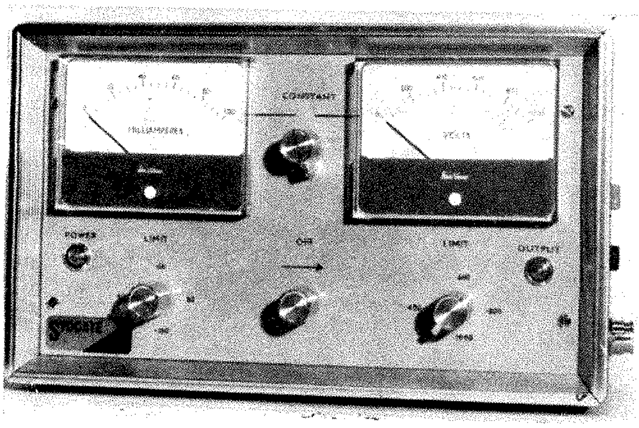
ELECTROPHORESIS POWER SUPPLIES



We now manufacture the largest range of power supplies, covering the range from 0.300 to 0.2500 volts with:

Constant current, constant voltage
Eight models in standard range
Specials made to order
Continuously adjustable
Two current ranges 100 and 200 MA
Adjustable limits on voltage and current

OTHER PRODUCTS

- Digital stop watches and timers
- Data conversion equipment

'MICHROME'

STAINS & REAGENTS FOR BIOLOGY

Acridine orange, Aquamount, Fluormount, Lipid crimson, Matamount, May-Grünwald, Leishman, Giemsa Toluidine blue, Cresyl fast violet, Papanicolaou stains, Thioflavine S, Brilliant cresyl blue, Nile blue, Pyronin Y, Trifalgic acid, Rhodanile blue, Haplo, etc.

CATALOGUE AVAILABLE ON REQUEST

DYES FOR USE IN ALL INDUSTRIES

RESEARCH & PRODUCTION CHEMISTS: if you are seeking dyes with specific chemical and physical properties suitable for particular manufacturing and/or testing processes you are invited to contact us for supplies.

We hold stocks of an enormous variety of dyes, ready for immediate despatch, including:

Cyanine, Dicyanine, Fast Bordeaux O, Aurantia, Crystal violet, BPC-Scarlet R, BPC, Diazonium salts, Neutral violet, Lacmoid, Nile blue, Janus green, Brilliant green BPC, Rosolic acid, Methyl green, p-Ethoxy-chrysoidin, Methyl red, Nitrazine yellow, Pinacryptol green, etc.

INDUSTRIAL RESEARCH ESTABLISHMENTS

are invited to make use of our professional services as consultants on the selection and use of dyes as research and production tools.

CSIRO

RESEARCH SCIENTIST

AUSTRALIA

WHEAT RESEARCH UNIT

GENERAL The Wheat Research Unit of the Commonwealth Scientific and Industrial Research Organization is housed in new laboratories in a wing of the Bread Research Institute of Australia with which it works in close association. It is on a site, eight miles from the centre of Sydney, accommodating several CSIRO Divisions. The Unit is engaged in fundamental studies of the wheat grain including the biochemical aspects of quality and reactions which occur during processing. The Unit is particularly well equipped to undertake protein fractionation and has good range of general equipment and excellent library facilities.

DUTIES The appointee will join a team investigating the physical, chemical and biochemical properties of the proteins, non-starchy polysaccharides, lipids and other components of the wheat grain. Initially he may be required to collaborate in fractionation and purification of his research materials. His previous training and experience will be considered in determining how he will participate in the overall research programme.

QUALIFICATIONS Applicants should have a Ph.D. degree in some field of physical chemistry or biochemistry or postgraduate research experience of equivalent standard and duration, supported by satisfactory evidence of research ability. Some experience in the fractionation and characterization of natural products or in the measurement and interpretation of oxidation reduction phenomena would be an advantage.

SALARY Depending upon qualifications and experience, the appointment will be made within the salary range of Research Scientist, $A6,139–$A7,789 p.a., or Senior Research Scientist, $A8,105–$A9,448 p.a. Salary rates for women are $A428 p.a. less than the corresponding rates for men. Promotion within CSIRO to a higher classification is determined by merit.

CONDITIONS The appointment, which carries with it Commonwealth Superannuation Fund or Provident Account privileges will be conditional upon passing a medical examination. An initial probationary period of twelve months may be specified. Fares paid for appointee and his dependent family. Further details supplied on application.

Applications (quoting Appointment No.: 651/32), and stating full name, place, date and year of birth, nationality, marital status, present employment, details of qualifications and experience, together with the names of not more than four persons acquainted with the applicant's academic and professional standing, should reach:

Mr. R. F. Turnbull,
Chief Scientific Liaison Officer,
Australian Scientific Liaison Office,
64 Kingsway,
LONDON, W.C.2.

by the **3rd April, 1970.**

Applications in U.S.A. and Canada should be sent to The Scientific Attaché, Australian Embassy, 1601 Massachusetts Ave. NW, WASHINGTON DC 20036.

(949)

UNIVERSITY COLLEGE HOSPITAL

GOWER STREET, LONDON, W.C.1

SENIOR BIOCHEMIST required from May 1, 1970, for interesting active Metabolic Research Unit. Excellent opportunity for own research project leading to postgraduate degree. Previous experience in clinical biochemistry is essential. Candidates wishing to see the Department should write to Professor C. E. Dent, F.R.S.

Application forms are obtainable from the Assistant Secretary to be returned by March 31, 1970. (977)

MEDICAL RESEARCH COUNCIL

(CLINICAL RESEARCH CENTRE)

Division of Immunology (Head of Division, Dr. G. L. Asherson) seeks chemist or biochemist with experience of polysaccharide chemistry to study the role of bacterial residues in human disease.

Salaries and conditions similar to those of Universities.

Further details from and applications to Personnel, Clinical Research Centre, 164 Tottenham Court Road, London WIP 9LH. (856)

SOUTH-EASTERN REGIONAL HOSPITAL BOARD

SCOTLAND

REGIONAL TRAINING SCHEME FOR BASIC-GRADE BIOCHEMIST

Applications are invited for the post of Basic-grade Biochemist in the training scheme operated jointly by the Departments of Clinical Chemistry at the Royal Infirmary of Edinburgh and at the Western General Hospital, Edinburgh. The successful candidate will be appointed to this position for one year in the first instance, renewable for a further two years.

Applicants should have graduated in Biochemistry or Chemistry or one of the related biological sciences, and the course of training will prepare him/her for the Mastership in Clinical Biochemistry.

Written applications, giving full personal particulars, details of training and experience, and the names of two referees, should be submitted to the Secretary, South-eastern Regional Hospital Board, Scotland, 11 Drumsheugh Gardens, Edinburgh EH3 7QQ, by March 31, 1970, from whom further details about the Training Scheme may be obtained. (919)

UNITED SHEFFIELD HOSPITALS

THE CENTRE FOR HUMAN GENETICS
SHEFFIELD

NON-MEDICAL SCIENTIFIC OFFICER

required for a period of 21 months to take part in research in the culture of amniotic fluid cells. Experience in Cytogenetics desirable but not essential.

Salary: 1st or 2nd Class Honours degree: £1,134 rising by 6 increments to £1,423. Other appropriate degree: £1,008 rising by 9 increments to £1,423.

Applications, stating age, qualifications, present and previous appointments, if any (with dates), together with the names and addresses of two referees: QUOTING REFERENCE SO2(CHG), to Chief Administrative Officer, United Sheffield Hospitals, 10 Beech Hill Road, Sheffield S10 2RZ, by March 14, 1970. (948)

UNIVERSITY LECTURESHIP OR A UNIVERSITY DEMONSTRATORSHIP IN THE DEPARTMENT OF GENETICS

The Appointments Committee of the Faculty of Biology "A" hope soon to be in a position to appoint a University Lecturer or a University Demonstrator in the Department of Genetics. Candidates should be able to teach mathematical genetics and may be expected to take part in the teaching of elementary statistics in general mathematical courses for biologists. Preference will be given to applicants who have had first-hand experience of biological experimentation. The appointment will be subject to the Statutes and Ordinances of the University, and will be for three years in the first instance, with the possibility, for a University Lecturer, of re-appointment to the retiring age, and, for a University Demonstrator, of re-appointment for two years. The maximum tenure of a University Demonstratorship is five years.

Candidates should send eight copies (only one for overseas applicants) of their application giving details, academic qualifications and experience, list of publications, and the names of three referees to Mr. R. E. Wyatt, Secretary of the Appointments Committee of the Faculty of Biology "A," Department of Zoology, Downing Street, Cambridge, CB2 3EJ, so as to reach him not later than April 1, 1970.

FREE UNIVERSITY AT AMSTERDAM

In the frame of the development of the section Chemical Physiology there will be in 1970 a vacancy for a

senior lecturer

This lecturer will participate in the instruction of biochemistry for medical students. At the same time a leading position in research will be assigned to him in cooperation with the professor and the second lecturer. The research is mainly directed towards the determination of the structure, localisation, formation and degradation of sialoglycoproteins and gangliosides in the brain-tissue.

Since the Free University emanates from a protestant though not church-bound association, it is kindly requested to add some information on personal orientation in this respect.

Applicants and those who want to mention other names are invited to direct themselves to prof. dr. H. K. Oosterhuis, Laboratory of Chemical Physiology, Van der Boechorststraat 7, Amsterdam, Holland, tel. (020) 482714.

(911)

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF ZOOLOGY

Applications are invited for two LECTURESHIPS and one DEMONSTRATORSHIP in the Department of Zoology. The following research interests are most pertinent to the needs of the Department but others will be considered: Animal behaviour, Animal genetics, Freshwater ecology, Animal locomotion, Entomology, Developmental biology, Comparative physiology.

Salary will be at an appropriate point on the following scales, according to age, qualifications and experience:

Lecturer: £1,240 to £2,850.
Demonstrator: £1,240 to £1,470 (extendable to £1,815).

Membership of F.S.S.U. required.

Further particulars may be obtained from the Registrar, The University, Newcastle upon Tyne NE1 7RU, with whom applications (three copies), together with the names and addresses of three referees, should be lodged not later than March 28, 1970. Please quote reference Na. (946)

IRELAND

Graduates in Engineering, Chemistry or Physics

are invited to apply for vacancies as Examiner in the Patents Office. Starting salary up to £2,045 (man) depending on qualifications and experience. The authorised establishment includes higher posts carrying salaries up to £2,770. Non-contributory pension. Widows and Orphans Pension.

Essential:

(a) A degree in Electrical, Mechanical, Chemical or Agricultural Engineering, **or**

(b) an honours degree in Experimental Physics, **or**

(c) an honours degree in Chemistry with two years' experience.

Age limits: 23–45 years. Further particulars, application forms etc. from The Secretary, Civil Service Commission, 45 Upper O'Connell St., Dublin 1, Ireland.

Latest date for receiving completed application forms—April 5. 1970.

(1017)

Microbiologist

(Veterinary Virology Research)

AUSTRALIA

The Commonwealth Serum Laboratories located at Melbourne, Victoria, require a Microbiologist to participate in the wide range of research projects aimed at a better understanding of the major infectious diseases of animals in Australia.

Duties: The successful applicant will be responsible to the Head of Veterinary Research for the conduct of veterinary virus projects and the direction of professional and technical staff involved.

Qualifications: Microbiologist with post-graduate training and/or wide experience in virology.

Conditions: Excellent conditions include commencing salary in the range, Male $A6,870 to $A7,570 p.a. Female $A6,430 to $A7,130 p.a. dependent upon qualifications and experience with eligibility for Superannuation, subject to meeting certain requirements.

Applications in writing to:

Personnel Manager, Commonwealth Serum Laboratories,
45 Poplar Road, PARKVILLE, VICTORIA, AUSTRALIA.
By April 18, 1970.

(925)

INTERNATIONAL FLAME RESEARCH FOUNDATION

HEAD OF THE RESEARCH STATION IJMUIDEN, HOLLAND

Applications are invited for the post of Head of the Research Station of the International Flame Research Foundation. The successful candidate, at least 30 years of age, with a Ph.D. Degree in Physics or Engineering will lead a small team of post-doctoral investigators, working on research into combustion and heat transfer of flames, sponsored by leading international industries and universities.

He should have some years' experience in leading research teams in a University or in a research laboratory in industry.

There is also a vacancy for a post-doctoral

RESEARCH INVESTIGATOR

having an Honours or Ph.D. Degree, to join the team working on problems of combustion and physics, in particular aerodynamics and heat transfer aspects of turbulent flames.

The work at the Foundation involves frequent contacts on an international level with research scientists working in similar fields, and the Foundation encourages publication of high quality original work.

The starting salaries will be not less than, £3,500 p.a. for the Head of the Research Station, and £2,000 p.a. for a Research Investigator.

Applicants should write in the first place to:

Professor J. M. Beer, Department of Fuel Technology & Chemical Engineering, University of Sheffield, Mappin Street, Sheffield 1.

(1008)

THE FUND FOR RESEARCH ON AGEING

In order to further ageing studies in the U.K., the Fund for Research on Ageing is offering a prize of £100 in each of the years 1970, 1971, and 1972 for work performed and published in the U.K. on EXPERIMENTAL GERONTOLOGY which is deemed by the assessors to have contributed the most to the study of

THE BIOLOGY OF AGEING

It is requested that reprints for 1970 should be submitted by April 30, 1971, to Dr. John Bray, Hon. Sec., Fund for Research on Ageing, c/o Angus Campbell and Co., Ling House, Dominion Street, E.C.2. (1007)

UNIVERSITY OF LONDON

CHAIR OF MEDICAL PHYSICS AT ROYAL POSTGRADUATE MEDICAL SCHOOL

The Senate invite applications for the Chair of Medical Physics tenable at the Royal Postgraduate Medical School. Salary (clinical) in the scale £4,470 to £5,275; (non-clinical) not less than £3,780 plus £100 London Allowance. The holder of the Chair will be Head of the combined Medical Physics Department of the Royal Postgraduate Medical School and Hammersmith Hospital and will work closely with the MRC Cyclotron and Radiopathology units. He will be responsible for research and postgraduate teaching in the fields of radioisotope applications, radiation dosimetry, medical electronics and physical techniques in diagnosis. Applications (ten copies) must be received not later than April 8, 1970, by the Academic Registrar (N), University of London, Senate House, W.C.1, from whom further particulars may be obtained. (865)

QUEEN'S UNIVERSITY

KINGSTON

DEPARTMENT OF GEOGRAPHY

The Department of Geography has the following vacancies at the present time.

1. Permanent Faculty Position. From September, 1970.

Preference will be given to candidates with specialisation in geomorphology. Teaching at both undergraduate and graduate levels with opportunities for research. Salary and status are subject to negotiation and will depend upon the experience and qualifications of the candidate.

2. Visiting Positions.

One visiting professor is required for September, 1970, and preference will be given to those candidates with a specialisation in economic geography. A second position will be available in January, 1970, and there is no limitation as to interest for the position. Both appointments will be for twelve months with salary being commensurate with qualifications and experience.

3. Instructors. From September, 1970.

Two Instructors are required to supervise the teaching by graduates in introductory laboratories and tutorials. The duties will also include the teaching of one laboratory section during the summer school session. Salary in range of $8,000 per annum.

Please send full details of qualifications and experience, together with the names of three referees, to:

Professor Brian S. Osborne,
Acting Head,
Department of Geography,
Queen's University,
Kingston, Ontario. (826)

UNIVERSITY OF THE WEST INDIES

BARBADOS

Applications are invited for (a) LECTURESHIP or (b) ASSISTANT LECTURESHIP IN CHEMISTRY Division of Natural Sciences, Cave Hill, Barbados. Candidates should have special interests in inorganic or physical chemistry. Salary scales: (a) £1,550 to £2,630 per annum; (b) £1,250 to £1,410 per annum. Child allowance. F.S.S.U. Family passages; triennial study leave. Detailed applications (six copies) naming three referees by April 7, 1970, by persons living in the Americas and Caribbean area to Registrar, University of the West Indies, Kingston, 7, Jamaica, and by all others to Inter-University Council, 90/91 Tottenham Court Road, London, WIP ODT. Further particulars obtainable similarly. (862)

THE UNIVERSITY OF HULL

DEPARTMENT OF PHYSICS

Applications are invited for appointment to a **Post-Doctoral Research Fellowship in Experimental** or **Theoretical Physics.**

Salary scale: £1,330 to £1,470 per annum.

Applications (six copies), giving details of age, qualifications and experience, together with the names of three referees, should be sent by April 17, 1970, to the Registrar of the University from whom further particulars may be obtained.

Why Pye Chromatography

The crowning success in the design of complex analytical instruments is the achievement of simplicity. You will find it in Pye Analytical Gas Chromatographs.
Take the simple, functional glass-to-metal seal, for example. It makes column changing quicker and easier, improves sensitivity by reducing contamination of the gas stream and pushes the effective working temperature of glass columns up to 350°C.
Pye gas chromatographs are easy to use because we design them to give you what you want in instrumentation – accuracy, reproducibility, flexibility, simplicity.
Two systems are available, both with a wide range of optional modules—
The Pye Series 104 Chromatograph for research or routine work, with many accessories including wide-range amplifier and auto-solids injection . . . and the Pye Model R Research Chromatograph with modular column oven, unique "total-loss" cooling system and simultaneous two column multi-detector operation.
To learn more about Pye chromatography including industrial instrumentation, the GM60 Gas Chromatograph-Mass Spectrometer system and the DP90 Datacon computerised chromatograph system, write or 'phone today.

NATURE Volume 225 MARCH 14

Are Graduate Students Worth Keeping?

THE way in which it now seems to have been decided in the United States that the federal government should spend less than in the past on the direct support of graduate students in American universities will be a slap in the face for those who have been saying that such an expenditure of public money should be recognized as a necessary part of the federal government's function. The most deeply hurt should be the National Science Board, which just a year ago produced an eloquent report (see *Nature*, **221**, 800; 1969) which argued that graduate education had become so central a part of public expenditure in science that the time had even come to consider spending money not simply on individual proposals for research but also at institutions or departments where important work in education was going on. One of the mysteries of public life is that this document seems to have sunk without trace—even its authors have been only fitful advocates in the past twelve months. What has happened now, on the face of things at least, is that the Administration has repudiated its responsibility for graduate education. Why else should the National Science Foundation have found this item struck from its budget (see *Nature*, **225**, 785; 1970)? Dr W. D. McElroy says that he (and Dr L. DuBridge as well) is prepared reluctantly to give the policy a trial for a year to see what happens. So far, the National Institutes of Health seem to have resisted more successfully the pressure to dispense with traineeships for graduate students. The fact remains that in 1971, and possibly in 1970 as well, the number of graduates at American universities will be much reduced. What is to be done?

In the long run, the easiest solution is no solution at all. It is widely expected that individual investigators will try to keep research students about them by including them as research assistants on grant applications. This, as it happens, is already a necessary device in places where the statutory stipend for a graduate trainee is not sufficient to cover the cost of living. The difficulty, of course, is that if the pensioners of the National Science Foundation seek to restore the *status quo* by adding all their possible research students to their grant applications, they will add something like $9 million a year—the amount of money now saved—to the cost of the foundation's research programme or, another way of putting it, the number of grant applications that can be satisfied will be reduced by 5 per cent. So what of the possibility that universities will be able to pay for some of the research students out of local resources, either endowments or state funds? The difficulty here is that the extra strain comes at a time when universities and their sponsors are already under severe pressure. There is something to be said for the view that there was virtue in the arrangement in the thirties when large numbers of bright people were supported through their postgraduate courses by half-time assistantships, but is there any reason now to believe that hard pressed state universities will be able to support the very much larger numbers now seeking entrance to graduate schools without at least some prior warning? And is it likely that after three years of anxiety about endowments, the private universities will be able to find money for this purpose? The chances are slim; moreover, there is as yet not nearly enough experience of loans for postgraduate students to suggest that the market will allow people to come forward in the numbers to which universities have become accustomed. In short, unless there is a sudden change of heart on the part of Congress, there is likely to be at least one lean year in the recruitment to the graduate schools and then, three to five years later, a diminished output of PhDs.

Universities and academics should restrain the first natural temptation to protest that this is an unpleasantness which is intolerable. To be sure, there is every reason to believe that running down the traineeship programme is misguided and every reason to hope that it can be reversed. But at the same time, however, this is also an occasion on which universities should ask themselves whether the pattern of graduate education in the United States to which everybody is accustomed is really the best suited for the modern world. The way in which employers (or potential employers) have taken to complaining of the over-specialization of the products of the graduate schools (see *Nature*, **225**, 897; 1970) is one sign that change may be called for. Most probably, in most branches of science there is a need to fit the pattern of graduate education more accurately to the kinds of work on which graduates are eventually engaged. At present, the academic interests of supervisors and the traditions of an over-rigid curriculum are too often dominant. It may be easier for the academic world to have the cuts in the traineeships restored if they can demonstrate innovations in the pattern of graduate education which seem more appropriate to the needs not merely of the modern world but of graduate students themselves. One of the ironies of the situation which has now developed is that the National Science Foundation seems, in a gingerly fashion, it is true, to be on the point of seeking to train people whom it calls "technologists"—how easy will this be now that money is so hard to get? The second irony is that the apparently defunct report on graduate education by the National Science Board would, if it had been taken seriously, have made it much easier than at present for academics to design graduate education to suit the graduates and not to make a particular grant application seem attractive.

Reform is thus the best guarantee of a redress of present grievances, but it is unreasonable to expect that it can happen quickly. The best that universities will have to offer is some sign of a willingness to change. But there is no quarrelling with the argument that the government cannot abandon its responsibility for graduate education without putting at hazard the whole basis on which the United States has achieved its pre-eminence in science in the years since 1945. The point is that graduate students are not merely the cheap research assistants they are sometimes thought to be but, rather, the people on whom society will depend for innovation ten years from now. The fact that people are now more worried about the environment than, say, about the need to keep industrial prosperity growing is beside the point. If there were, ten years from now, a decline in the capacity of industry to transform itself—and it could happen as quickly as that—most probably it would be too expensive to make the serious improvements of the environment now sought. It is true, of course, that a reform of graduate education would work the other way, and would enhance the innovative potential of graduating students, but that is only another reason for pressing on with reform. In the meantime, the universities have only themselves on which to rely in making a case for their own survival. If they can rise successfully to the challenge, and can make a stronger and more coherent case than they have done so far for the importance of training graduates, the present crisis may be a blessing in disguise. Otherwise, it will be a disaster.

100 Years Ago

Turning now to the concluding chapters of the book, we meet with some of the most startling and suggestive ideas to be found in any modern work. The law of deviation from an average enables us to determine the general intellectual status of any nation, if we are able to estimate the ability of its most eminent men, and know approximately the amount of the population. We have these data in the case of ancient Attica ; and Mr. Galton arrives at the conclusion, that the Athenians of the age of Pericles were, on the lowest possible estimate, nearly two whole grades of ability higher than we are. With all our boasted civilisation, and the vast social and scientific problems with which we have to grapple ; with all our world-wide interests, our noble literature, and accumulated wealth ; the intellectual status of the most civilised modern nation is actually lower than it was more than two thousand years ago !

From a review by Alfred Wallace of Francis Galton's Hereditary Genius, an Inquiry into its Laws and Consequences. From Nature, **1**, 502, March 17, 1870.

OLD WORLD

COMPUTER POLICY

Mintech Under Fire Again

THE row over the government's policy of computer procurement—which began when IBM (UK) appeared before the subcommittee of the Select Committee on Science and Technology which is investigating the computer industry—hotted up last week when it was the turn of Honeywell to meet the subcommittee. The question is how large a share of the public computer market the subsidiaries of American companies such as IBM and Honeywell, which have extensive factories in Britain, can reasonably expect to corner. IBM (UK) set the ball rolling when its managing director, Mr E. R. Nixon, told the subcommittee of his belief that non-British companies have to tender 25 per cent lower than International Computers Limited (ICL) to get government orders (see *Nature*, **225**, 889; 1970). The IBM team stressed how unfair this is by going on to list the benefits bestowed by IBM (UK) on Britain; £33 million of the company's revenue of £125 million in 1968 came from exports, and although imports of £38 million led to an unfavourable contribution to the balance of payments, the situation seems to have been reversed last year.

Last week's witnesses from Honeywell Ltd, led by chairman and managing director Mr L. R. Price, started from a firmer base and went farther than IBM in its criticism—in the twelve months up to September last year, £16·3 million of Honeywell's sales of £37 million went to export, compared with an import bill of £11·8 million. But it is not in fact government policy that Honeywell is complaining of so much as that the stated policy is apparently not being followed. The Honeywell team brought to the notice of the subcommittee several statements by government spokesmen affirming that subsidiaries of non-British firms manufacturing in Britain stand on an equal footing with British companies such as ICL when it comes to orders for the public sector, which is fine as far as Honeywell is concerned, but Mr Price and his colleagues alleged that the figures tell a different story. Out of 75 systems in central government, 69 were made by ICL, four by IBM and two by Univac.

Taken to task by the subcommittee, the Honeywell representatives agreed that in individual cases their machines might have been unsuccessful for reasons of compatibility, price or performance. But Mr Price and his colleagues said that this is not the whole story because the figures for the public sector have to be compared with Honeywell's more respectable share of the private market, where the Ministry of Technology has no influence. Honeywell's share of sales to the entire public sector which includes local authorities and universities is a little more than one-third of its share of the private market. In its written evidence to the subcommittee, the company states that "It is apparent that foreign-owned companies, whether or not they manufacture in Britain, are largely excluded from the increasingly important public sector of the market".

The government practice of sometimes inviting tenders from ICL only, raised by Mr Nixon of IBM, also came under fire, and the Honeywell team thought that the practice was probably on the increase. But they agreed with Mr Eric Lubbock of the subcommittee that single-tendering is more honest than requesting tenders when there is no intention of ordering, which the Honeywell team suspected might have been happening. Mr Price thought that some cases of single-tendering were completely correct when the choice was a foregone conclusion for reasons of compatibility of computers, but he nevertheless believed that Honeywell's share of the market indicates that they are being discriminated against.

Honeywell's estimate of the British market for both business and scientific machines rises from £150 million in 1968 to £170 million in 1969, £210 million in 1970 and £260 million in 1971. With much of the growth expected to be in the public sector, Honeywell believes the government ought to practice what it preaches about the position of foreign-owned firms which manufacture in Britain, especially those with a positive trade balance. For one thing, it would help if government departments made known their reasons for choosing a particular computer. The subcommittee will also be trying to discover precisely what are the guidelines for computer purchase laid down by the Ministry of Technology which seem to produce such a discrepancy between theory and practice. These are questions to be reserved for the Minister of Technology who is expected to appear later in this enquiry which is already noted for the searching questions coming from the subcommittee.

SATELLITES

Aquiver to Join the Space Club

Britain took a step nearer becoming the fifth member of the "space club" last week with the successful launching of the Black Arrow 3-stage satellite launch vehicle from Woomera on its second flight test. On the first launching, made last summer, the rocket had to be destroyed because of a failure in an electrical circuit in the control system. The Mintech team in charge was sufficiently confident that the trouble had been located and put right to move on to the second of the three scheduled flight tests without holding up the timetable for a repetition. They were justified by satisfactory performance in all the three stages last week.

At the next firing later this year there will also be a trial of the satellite injection system on the third stage so that, if successful, a nominal satellite will go into orbit. This will then put Britain square with the Japanese whose small satellite launcher orbited a nominal payload for the first time last month (*Nature*, **225**, 678; 1970), although the satellite ceased to transmit a few hours after launch because of a failure in the electrical supply system. Meanwhile, France is expected this week to launch her fifth satellite with a French built rocket. This will be the first satellite to be launched from the new French rocket range, on the equator at Kourou, French Guiana.

Black Arrow's planned payload capacity is of the order of 100 kg when launched north into a polar orbit, or 150 kg if launched easterly from an equatorial range. This is slightly in excess of the payloads of the comparable French and Japanese launchers. The purpose of the programme, finally given the go-ahead by the government three years ago, is to provide a modest technological capability in satellite launching and construction and associated activities. Three satellites have so far been commissioned, of which the first, essentially a "housekeeping" vehicle, should be orbited in 1971. Black Arrow satellites are to provide an orbiting test bed for trying out and proving various experimental ideas and components. Among the likely candidates are communications satellite components and instrumentation for operational weather satellites. So far the Black Arrow budget has been running at about £3 million a year which is expected to rise to £5 million from now on.

The launch vehicle itself has been developed from the proved components and technology of the highly successful British Black Knight high altitude sounding rocket that carried out a re-entry test programme for the Ministry of Aviation in the early 60s. It achieved the then unbeaten record of 21 successful test launchings out of 21. Black Knight was developed by the Saunders Roe aircraft company, based in the Isle of Wight, which was later taken over by the division of Westlands that has become the British Hovercraft Corporation. This group is the prime contractor for Black Knight's successor, Black Arrow, with the curious result that the British satellite is to be launched into space through the efforts of an industry associated with hovering and at heights of only a few feet at that.

RABIES

End to Compromise

A ban on the import of dogs, cats and all other felines and canines into Great Britain was announced last week by Mr Cledwyn Hughes, Minister of Agriculture. The ban will be waived only for animals from Ireland, the Channel Islands and the Isle of Man. Mr Hughes is also setting up a committee of enquiry on rabies which will review the whole quarantine scene, but in the meantime imported animals that are already in the country will have to complete twelve months in kennels before they can go free.

The British quarantine regulations have now been overhauled twice in three months. Last December the length of quarantine went up from six to eight months after a rabid dog, not long out of kennels, ran wild in Camberley (see *Nature*, **224**, 634 and 1049), and at the same time a number of more exotic species were forbidden entry to Britain. The new restrictions were prompted by a mongrel which died from rabies at Newmarket on February 27, nine months after arriving from Pakistan.

Mr Hughes seems to have taken the only course open to him in order to preserve Britain's enviable record of freedom from rabies since 1922; a second large increase in the quarantine period without cutting imports would not have been practical. The alarming spread of rabies in wildlife on the European continent is one justification for being strict. Mr Hughes's case also rests on the uncertainty about the incubation period of rabies, but leaves room for relaxing stringency later by asking the committee of enquiry "to review the policy and precautions against rabies in Great Britain and to make recommendations". Chaired by Mr Ronald Waterhouse, QC, the committee is expected to report within a year but may speak sooner if it finds an urgent need for more action.

The government will be paying for the extra four months' quarantine, but response to the changes has been ambivalent. The Royal Society for the Prevention of Cruelty to Animals said that "the minister had, in making his proposals, consulted the best veterinary opinion in the country, and . . . we can only accept the regulations", although "since quarantine represents a hardship for animals, we find it disturbing that the period should increase from eight to twelve months". The secretary of the Canine Defence League, Mr A. H. Roosmalecocq, thought the ban might be justified as a temporary measure, although he considered twelve months' quarantine "unnecessarily drastic" and suspected the minister's advisers were "covering up while they do their sums again". Taken at face value the prohibition covers laboratory animals just as much as pets, although when the order is actually made it may allow some exceptions for research; at the time of his announcement Mr Hughes was not able to say what would happen. The Medical Research Council, at least, is not worried by any potential loss, for it either breeds its own cats and dogs or buys them from accredited British breeders, and says it "certainly wouldn't import them under any circumstances".

One obstacle to complete safety remains, however, and that is smuggling. The maximum fine for smuggling an animal into Britain is £200—increased from £50 in 1967—and may well prove too small to deter a really desperate dog-lover. In practice, fines have been nowhere near the maximum, and some magistrates have been known to impose derisory penalties of £5 or so. Here, it seems, the committee of enquiry might find one of its priorities.

UNIVERSITIES

Teaching of Physics

FEW physicists can feel indifferent to the way physics is taught and a lively audience arrived last week at the physics exhibition in Alexandra Palace, London, to hear Professor E. J. Burge, of the Chelsea College of Science and Technology, proclaim there are at present far too many examinations. He thought that some more continuous form of assessment should be introduced, including oral tests. But he was against attempts to dismember physics as a subject. "I believe that physics is an academic discipline that holds together as a whole, and efforts to turn it into a series of service courses will be vigorously opposed."

Professor E. H. S. Burhop of University College, London, took a rather different view. He foresaw the emergence of a new subject comprised of topics from both physics and chemistry. University College has recently introduced a joint chemistry and physics course, which is no soft option, he said. But the pattern of education is changing rapidly. If the proposed Qualifying and Further examinations (intended to replace O and A level) come into being, physics will only be taught at school as part of the physical sciences, Professor Burhop said. With the government eager to keep down the cost per head of education, there could be a lot of wisdom in introducing four year courses for bright students and teaching the less academically inclined for only two years.

On postgraduate teaching, Professor Burhop thought there was value in the present emphasis laid on teaching postgraduates to dissect a specific problem, to scan and assess literature and perform specific functions like data analysis, but conceded that a lack of general technique was proving a handicap to those going into industry. A physicist might now finish his PhD as an expert in, say, bubble chambers or counters and with considerable incentive to continue working in the same field. This would have to change, he said. But industry for its part was still too ready to treat physicists as technicians.

Professor Burhop also criticized the Institute of Physics and the Physical Society which, he said, was far too timid in creating a dialogue between industrial and academic physicists. He also thought the Science Research Council was wrong to increase the proportion of postgraduate grants given for advanced studentships rather than for MSc and PhD courses. For one thing, staff was short and these courses often turned out to be very uninspiring. But the SRC's CAPS awards (Co-operative Awards in Pure Science) which give a student one supervisor in industry and one at university were proving a success in providing more "industry oriented" physicists.

UNIVERSITIES

Revamping the Vets

THE way in which veterinary science is taught in Britain needs a thorough overhaul—this, at least, was the conclusion of a two-day conference held last week by the Royal College of Veterinary Surgeons. The college, which officially supervises university veterinary courses, has asked the government to set up an interdepartmental inquiry into the education and future role of the veterinary profession, a request which is being urgently considered.

The chief disadvantage of the present system, it seems, is that the universities are failing to produce the flexible, well-educated type of veterinary scientist who is needed. The system, which has remained largely unchanged for the past thirty years, is becoming increasingly inappropriate in view of the widening range of veterinary activities. On the clinical side, general practitioners are being expected to cope with the problems of large herds, and particularly the problems of disease prevention in intensive animal production systems. There is a growing demand for clinical species specialists but as yet very few opportunities for specialist training. Commercial activities such as the development and testing of new medicines, food additives and agricultural sprays are becoming increasingly important. More graduates are needed in research, particularly in new fields such as veterinary epidemiology, but here also there are no facilities for postgraduate teaching. This point did not escape the attention of the Swann committee, which in its report on the use of antibiotics in veterinary medicine recommended that university departments of veterinary epidemiology should be set up.

Most of the speakers at the conference agreed that the universities or research establishments should offer many more postgraduate courses. Dr J. T. Stamp from the Moredun Research Institute in Edinburgh suggested that, following the normal five-year undergraduate course, all students intending to go into practice or other clinical fields should have to take an extra year of postgraduate professional training. For research scientists, Dr K. N. Burns from the Agricultural Research Council suggested that a period spent in practice would probably be helpful, but that the transfer to further research training should be made easy. There seemed to be general agreement that the first two or three years of the undergraduate course should provide a broad scientific training, and possibly be taken in conjunction with other medical and dental students, while the next two or three years should provide the necessary vocational training. Sandwich courses were suggested, by Dr J. T. Done from the Ministry of Agriculture, as a means for giving the students a feel for veterinary practice.

INDEPENDENT UNIVERSITY

£15 Million to Launch

by our Education Correspondent

To launch a self-financing university that is free from state control is a difficult business. That, if nothing else, is the first conclusion to have been drawn by the planning board of the proposed Independent University. Not only are supporters of the university laid open to the criticism that it will be merely an extension of the public school with industrial control in the place of state control, but they are now faced with the fact that the estimated cost of launching the university has trebled in just over a year. A policy document put out by the planning board suggests that £15 million will be needed to get the university off the ground. In January 1969, when the idea was first mooted, it was thought that £5 million would do the job.

The supporters of the university are not despondent, however. They believe that £15 million "should not be beyond the pocket of a wealthy nation concerned to preserve the best in its university tradition", and they hope that this money will come from endowments, loans, guarantees and gifts in kind. Once over the first few years it is intended that the university will be self-financing. Students will have to pay economic fees ranging from about £650–£700 a year for arts students to £1,050–£1,100 for science students. These figures do not include maintenance, but the planning board can see no reason why independent university students should not qualify for grants from public funds. It also argues that a system of loans would help such students to finance themselves, and would prevent the university from having to take only children from rich families, and therefore from becoming merely an extension to public school. The cost to the student over three years would be nearly £5,000.

One criticism often levelled at the proposed Independent University is that it will find difficulty in attracting staff of sufficiently high quality. But the planning board's answer to this seems to be that the university will not be bound by UGC scales of pay, and will place great emphasis on teaching ability when selecting staff. The planning board also believes that the university should be located on the outskirts of London, and the secretary of the board, Mr MacCallum Scott, indicated that some sites are already being considered. Although a site in the provinces cannot be ruled out, the planning board suggests that proximity to London's facilities will offer great advantages.

Before the university can award degrees, it must first receive a royal charter, and there seems little chance of this for several years. It seems, therefore, that if the university does get off the ground, it will be at least four or five years before it starts to operate, and even longer before it reaches its proposed size of 3,000 students.

MATHEMATICS

Differentials in Low Gear

Too little research on differential equations is being done in Britain, according to the interim report of the panel set up by the mathematics committee of the Science Research Council to review both pure and applied work on differential equations. There is not much research activity in Britain on most aspects of ordinary differential equations, for example, and the panel finds the amount of study of non-linear partial differential equations to be "most unsatisfactory". To rectify the situation amounts virtually to the introduction of new subjects to Britain, and the panel lists three ways in which this might be achieved—by year-long symposia, by a long term programme of visitors from abroad, and by the exchange of personnel with experienced overseas groups.

Established in June 1967 under the chairmanship of Professor I. N. Sneddon of the University of Glasgow, the panel is expected to continue regular meetings for a further two or three years. The interim report includes the familiar homily about poor communications between universities and industry, which the panel feels is hampering the development of such topics as control theory, for instance. In general, what is required on the industrial side is a better formulation of industrial problems, and a readiness of university mathematicians to be more involved in the application of differential equations. How this ideal is to be achieved the panel recognizes to be a problem with no easy solution, but it suggests the trial of methods such as the joint study group between universities and industry which is being tried by the Oxford Mathematical Institute, and the publication of a comprehensive survey of techniques.

To give the subject of differential equations a boost the SRC has already begun to set aside twelve research studentships per year for graduates working in this field, and the report recommends that this experiment be continued for five years. The panel says that over the next five years or so there should be one large symposium each year on some aspect of differential equations (one has already been held at the University of Warwick) and they favour more universities increasing their interest in this field.

INFORMATION

Literature Taped

from a Correspondent

THOSE biologists who count as wasted the time spent tracking references to their particular research interest through the paper jungle of literature search indices will welcome news of an experiment, currently in progress in Britain, which may presage an end to their labours. The experiment, which is financed by the Office of Scientific and Technical Information (OSTI), aims to ascertain just how valuable a computerized literature searching service could be to biologists.

The two year project has been established at Oxford University, in close collaboration with the Experimental Information Unit already based there, and a subsidiary experiment is being developed along identical lines at Nottingham. Three liaison scientists, two in Oxford and one in Nottingham, have been appointed and the first stages of the experiment are already under way. The project centres around BA-Previews, magnetic computer tapes on which are recorded all the items of literature surveyed in the journal *Biological Abstracts* which appears twice a month. BioSciences Information Service (BIOSIS), the American non-profit-making organization which publishes *Biological Abstracts*, sees these taped previews as the latest advance in the battle to rationalize and classify the ever mounting torrent of biological literature. The tapes have therefore been made available to OSTI for one year free of charge in return for a feedback of information from the British project. The tapes can be searched quickly and efficiently by a computer programmed to provide a print-out of references corresponding to a particular "user profile". This is a series of keywords which the computer can recognize in several different permutations and combinations so designed that items of specific interest only are selected from the ten thousand or so on each preview tape. Retrieval systems of this nature have been available to chemists, physicists and medical workers for some time—MEDLARS, the Medical Literature Analysis and Retrieval System is one example—but such a facility will be a considerable novelty to biologists.

The immediate aim of the liaison officers at Oxford and Nottingham is to recruit a limited number of biologists both from the universities and from kindred establishments. From information provided by these selected users it is hoped to find out how effectively the literature is scanned by the abstracting service, how best to formulate subject profiles for biologists, and, most important, to compare the performance of the computer-based service with more conventional methods of information retrieval.

BIOSIS hopes eventually to extend the range of its BA-Preview tapes, at present covering only current material, to include the contents of all *Biological Abstracts* back to 1927; the prospect of having the entire literature survey for a review prepared in minutes by computer is surely enough for most biologists to hope that the OSTI experiment proves successful.

POLLUTION

Why Lead gets into Petrol

THE furore over the presence of lead in petrol and the announcement of lead-free petrols by major oil companies have arisen not so much because of the health risk, which is uncertain, but because of the harm wrought by lead compounds in exhaust gases on the antipollution devices which manufacturers are being urged to fit to cars in order to trap the more noxious products. Although lead, in the form which it is added to petrols—tetraethyl lead, $Pb(C_2H_5)_4$—is undoubtedly poisonous, and nobody is ever happy about the presence of lead compounds in the atmosphere, there seems to be no evidence so far that the amount of lead released from engines is hazardous. There is, however, some concern that the background level of lead from exhausts might conceivably be building up, which is why some people are calling for a reduction in the amount of tetraethyl lead in petrol so as to keep in step with the increase in the car population.

The presence of lead in petrol is felt to be of concern because of an indirect effect on the pollution problem. In theory the exhaust products of a petrol engine should be CO_2 and H_2O, but in practice, of course, pollutants such as CO, oxides of nitrogen, and unburnt and partially burnt hydrocarbons are released. One way to trap some of these undesirable gases is to fit catalytic gas treaters which look rather like an extra silencer into the exhaust system, but unfortunately the lead compounds in the exhaust gases, presumably for the most part oxides, poison the catalyst and make its lifetime unacceptably short. If the life of the catalyst is too brief, the gas treaters are not likely to be replaced often enough to keep the pollution level down.

The value of adding tetraethyl lead to petrol was first realized by Thomas Midgley, Jun., in the United States in 1922, and now quantities up to 4·8 ml. per UK gallon are added, usually as a mixture of tetraethyl and tetramethyl lead, when the products of the refinery are blended to produce the required petrol. Its role is as an anti-knock compound, to prevent the unpleasant effects of explosive burning ahead of the flame front in the combustion chamber. What ought to happen is that the flame front propagates smoothly across the combustion chamber from ignition at the spark plug, but sometimes the gas mixture in front of the flame is compressed enough for spontaneous ignition to take place. Besides the unpleasant noise, the shock wave so produced is damaging to the engine. It is still not clear exactly how the addition of tetraethyl lead inhibits the uncontrolled burning which is the cause of knocking.

The addition of tetraethyl lead can improve a petrol by as much as six octane numbers, which is hard to compensate for by other means. The alternative to additives for knock reduction is to lower the pressure in the combustion chamber, in other words to reduce the compression ratio. This allows petrols with octane numbers as low as 91 to be used, which probably can be produced fairly easily without lead. This seems to be the direction which is being taken in Detroit with compression ratios being lowered to around 7:1. Unfortunately the problem is less tractable in Europe, where motor car engines tend to be smaller than in North America, so that reductions in the normal compression ratios (usually around 9 or 10:1) and commensurate reductions in the octane number of petrols would be more seriously felt. The production of petrols with high octane numbers without adding tetraethyl lead is more difficult; other additives with anti-knock properties are known, but none seem to be as good as lead, and the alternatives (such as certain aromatic compounds) could be just as much a nuisance from the pollution point of view. Increasing the octane number by the addition of synthetic hydrocarbons is ruled out because of the expense of breaking down the crude oil and rebuilding in the desired form. It seems that in the long run motorists will have to get used to lower compression ratios.

Parliament in Britain

Gas Centrifuge Agreement

The agreement to develop the gas centrifuge process for enriching uranium, signed last week by Great Britain, Holland and West Germany, may later be extended to include Italy and Belgium. Mr David Luard, Joint Under Secretary, Foreign and Commonwealth Affairs, said that discussions are taking place with these countries, and both have formally expressed interest in joining the agreement. Mr Luard also gave an assurance that stringent safeguards and security arrangements have been written into the agreement. (Written answers, March 2.)

Polytechnics

Eighteen major building projects for polytechnics, at a total cost of £6·2 million, have been given the go-ahead for 1970–71. Between 1967 and 1970, further education building programmes have included projects worth £17·7 million at colleges now forming part of designated or proposed polytechnics. These figures were given by Mr Gerald Fowler, Minister of State for Education and Science, and later the Secretary of State, Mr Edward Short, said that the proposed polytechnic at Huddersfield will probably be designated on September 1, 1970. Fourteen polytechnics have so far been designated. (Written answers, March 5.)

Fluoridation

The government may be forced to bring in legislation to compel local authorities to introduce fluoride into water supplies. This warning was given by Mr Richard Crossman, Secretary of State for the Social Services, after he had said that however much time, money and trouble are taken, eyes that are determinedly closed cannot be opened. His department, he said, has spent £300 this year to promote the case for fluoride in water supplies, but Mr Frank Judd asked for higher priority to be given to supplying authentic and appropriate information to local authorities on fluoridation. Mr Judd said that a number of authorities are taking half baked decisions on the basis of totally inadequate information. (Oral answers, March 9.)

Pneumoconiosis

The greater weight of respirable dust particles in South Wales coalmines may be the reason why the incidence of pneumoconiosis in the South Wales coalfield is almost twice as high as in other British coalmines. Accordingly, from the end of this month, new dust standards, based on the weight of dust in the atmosphere, will be introduced in all mines operated by the National Coal Board. This announcement was made by Lord Delacourt-Smith. (Oral answers, Lords, March 5.)

Strategic Nuclear Deterrent

Mr Denis Healey, Secretary of State for Defence, said that the government has no plans for modernizing Great Britain's nuclear deterrent, although the effectiveness of the Polaris system is kept constantly under review. Sir Ian Orr-Ewing asked whether reports that the government has refused to modernize Polaris missiles are true, but Mr Healey replied that steps had already been taken to improve the penetration capability of Polaris following the news of a Soviet ABM system. (Oral answers, March 4.)

Miscellaneous Intelligence

"The real purpose of the book I am writing is to say the human race is not so bad, after all. It can produce cancer workers. I have tremendous admiration for them; I think they are doing absolutely marvellous work; and I am proud to be a member of the same race"—Bernard Glemser in *Man Against Cancer* (Bodley Head, London, 1970). "Were it not for the tremendous amounts of money available, wrung from a susceptible public by an obviously emotional appeal, I suspect that very few scientists would be working directly on cancer. It seems to me that the mechanism of cancer is most unlikely to be discovered until pure biologists have unravelled a great deal more about the fundamental processes which go on inside a normal living cell. Most competent biologists probably realize this and avoid working directly on the problem of cancer. As a result, many research workers in the cancer field, I fear, are equipped with more dedication and money than scientific ability"—David Horrobin in *Science Is God* (Medical and Technical Publishing, Aylesbury, 1970).

According to a list prepared by Professor A. M. Liquori, head of the Laboratory of Physical Chemistry and Electrochemistry at Rome University, his department published no less than 63 papers during 1967–69. Professor Liquori is author or co-author of 42 of the 63 papers.

The view that the Irish are unduly partial to alcohol has been irrefrageably refuted. Figures compiled by the Economic and Social Research Institute in Dublin and reported in the *Journal of the Irish Medical Association* (**63**, 39; 1970) reveal the sober truth that Ireland is among the least bibulous of nations, consuming each year only 102 pints of beer a head compared with the Englishman's 164 pints and the German's 224. This being the case, how can the myth of Irish drunkenness have arisen? Possibly from the untypical propensities of the Irish immigrants to the United States, the Dublin Institute cannily suggests. Perhaps—but under what kind of influence could James Joyce have been when he wrote "Ireland sober is Ireland stiff".

Is the civilized world really awake to the true perils of cannabis? In South Africa they are not deceived. According to Mr Richard Neville, the editor of OZ (in *Play Power*, Cape, London, 1970), a South African textbook of criminology warns that "in extreme cases marijuana can so destroy a man's character that he mixes freely with persons of another race".

The following genealogical conundrum is posed in a current issue of *Zootecnica e Veterinaria* (**11–12**, 281; 1969): "Chauries have originated from Yaks (female is known as Nak) and Khirkoo and Jolung bulls on lower hill Zebu cattle. The female of Yak which is commonly known as Nak produces chauries when crossed with a bull locally known as Khirkoo and Jolung. Chauries are further subdivided into two types depending on different combinations of parents. Chauries obtained by crossing Nak (mother) with Jolung or Khirkoo bulls (father) is called as DIMJU and is supposed to be of a better quality than the one called URUNG which is obtained by crossing lower hill cows (Zebu cattle) with Yaks." Dimju jolung a chaury urungn't you the nak?

NEW WORLD

Keeping Plowshare Alive

THE stiff upper lip which the Atomic Energy Commission has kept for the news that Project Plowshare will be cut almost in half in the coming financial year seemed to tremble a little last week when the director of the Division of Peaceful Nuclear Explosions, Mr John S. Kelly, gave an account of his plans to the Joint Committee on Atomic Energy. For one thing, Mr Kelly seems to be hoping that news of the Russian development of peaceful nuclear explosions now being made available to a technical panel at the International Atomic Energy Agency in Vienna will help to win back support for his programme. Dr Michael M. May, director of the Lawrence Radiation Laboratory at Livermore, California, went so far, at the authorization hearings on the AEC's budget for 1971, as to suggest how an extra $10 million could usefully be spent in 1971.

Over the years, Project Plowshare has been under increasing financial pressure. In the financial year 1967–68, the budget was a heady $17·8 million—this was the year in which the AEC exploded a row of nuclear charges so as to simulate a section of what might yet be a sea level canal across the Isthmus of Panama. (The commission studying that proposal is due to report at the end of 1970.) A year ago, the AEC asked for $29 million for the current fiscal year and received just half that amount—$14·5 million. In a statement that has just been made public in a report by the Joint Committee on its Plowshare investigations last year, the AEC says that it had been hoping for $44 million in the new budget—more than five times as much as it has been given—and that it foresaw a programme of roughly the same size and cost for at least the next four years.

The chief effect of the new financial restrictions in the coming year is that there will be no experiments with nuclear explosions intended for excavation but only laboratory analysis of work already carried out. By the same test, the AEC will have to postpone its plans for making elements with atomic number greater than 104 by the use of nuclear explosions, although some theoretical studies in the design of nuclear explosives are intended. The only explosion will be that of a device intended for underground engineering—this will take up $1·3 million. The object is to develop a nuclear device more suitable than those now available for stimulating the flow of natural gas from underground reservoirs, principally by reducing the amount of tritium produced in the explosion. Mr Kelly said last week that it should by 1973 be possible to use "improved explosives" producing amounts of tritium about one per cent of those found in the gas from Project Gasbuggy, the underground explosion in December 1967 in New Mexico. Another objective is to produce a nuclear device small enough to be lowered down a conventional drill pipe six or eight inches across.

The most obvious weakness in the case for Plowshare is that no overwhelming economic case has yet been put forward. The results so far available from the Gasbuggy programme are encouraging enough—Mr Kelly said last week that the project had been a success "by almost any criteria", and that the underground explosion had increased the amount of gas which it would be possible to extract in twenty years from the reservoir to 900 million cubic feet, five times the capacity of similar wells operated conventionally. With gas selling at the well head at 13·3 cents per thousand cubic feet, this implies a total value of more than $100,000. Even though the cost of distribution is an increasing fraction of the total cost of selling natural gas, it is unlikely that such a comparatively small increase in the productivity of a well will bring hydrocarbon companies clamouring for Plowshare projects. The fact is that it is not yet clear how safely natural gas laden with tritium could be fed into the public distribution system—Gasbuggy gas is at least 25 times as heavily laden with radioactivity as the distributors would like to see it, with the result that the material now being bled from the reservoir is burnt on the spot. Perhaps more will be known of these problems when the AEC uses $100,000 of its new budget to drill a hole towards the underground cavern left by Project Rulison, 8,000 feet below western Colorado. Another puzzle to be solved is that the pressure in the Rulison cavern seems to have increased rapidly in the last three months of 1969 until it had reached more than one ton per square inch by the end of the year, presumably because of the release of gas from elsewhere in the reservoir, but Mr Kelly said it is now

AEC BUDGET
(in thousands of dollars)

	1969 actual	1970 est.	1971 est.
Raw materials	100,904	50,800	18,016
Special nuclear materials	328,664	321,360	348,518
Weapons	816,279	808,150	841,760
Reactor development	443,399	424,000	432,034
Physical research	273,944	278,180	274,430
Biology and medicine	88,779	89,450	88,300
Training, education and information	16,250	15,068	12,780
Isotopes development	6,718	5,890	6,000
Civilian applications of nuclear explosives	12,959	14,500	8,000
Communities	6,334	9,981	7,844
Regulation	9,316	11,725	12,672
Programme direction and administration	96,217	108,701	111,128
Security investigations	7,178	8,530	8,370
Cost of work for others	21,063	42,881	24,246
Adjustment to prior year costs	−560	—	—
Total programme costs	2,227,444	2,189,216	2,194,098

stabilized. Until these questions are resolved, Mr Kelly's claim last week that nuclear stimulation of underground gas wells could make available some 317,000 million cubic feet of gas, more than the present proved reserves in the United States, will no doubt remain a paper promise—and the chairman of the joint committee, Mr Chet Holifield, wanted in any case to know why 50,000 million cubic feet of gas should be shipped to Japan each year if the shortage of natural gas was as serious as Mr Kelly said.

In the new straitened circumstances, most of what Plowshare has to spend will go on research, partly in the design of improved explosives, partly in the better understanding of the mechanical effects of nuclear explosions and partly in trying to anticipate the production of radioactivity in novel circumstances (such as in copper bearing strata) and the production of geothermal heat.

This said, it seems clear that the reduction of effort will have serious consequences, particularly at Livermore. Mr Kelly said last week that a delay of a year or more in the cratering experiments would mean that the project would lose engineers and scientists. Dr May said that there would be a good many scientists among the eighty out of two hundred people who would be leaving Livermore, a laboratory already under pressure because of a seven per cent reduction in the weapons programme. This argument no doubt gave point to Dr May's programme of supplementary work, including a second underground explosion, the drilling of extra holes for geophysical exploration around the Rulison reservoir, experimental studies of an existing underground gas reservoir to determine leaks, studies of other existing cavities and of the proposals which are, according to Dr May, streaming in to the AEC.

The extent to which tales of what the Russians are doing will melt the heart of Congress remains to be seen. According to Mr Theos J. Thompson, an AEC commissioner, the Soviet Union has already carried out several peaceful nuclear explosions as part of a development programme by the State Committee on Atomic Energy. The meeting in February, the second between the Soviet Union and the United States, showed that the Russians have already carried out five excavation experiments, two of them with rows of explosives intended to form a trench, and a 25 kiloton underground explosion intended to produce an underground gas reservoir, while there are also plans to stimulate natural gas and oil production. Although this development seems to indicate a change of policy in the Soviet Union since the early sixties when there was vigorous criticism of the American plan for Plowshare, there is nothing in what Mr Thompson said last week to suggest that the Russians have significantly improved on experiments already carried out in the United States, or that they have been able to avoid some of the difficulties in the way of Plowshare. Indeed, talk of diverting rivers to balance water evaporation from the Caspian Sea probably has the same status in the Soviet Union as the American plan for a sea level canal across Central America.

One of the ironies of the AEC's new programme is that comparisons between the United States and the Soviet Union are chiefly responsible for the most striking, if modest, increase in expenditure—the proposals for more spending on thermonuclear research machines. Last week, Mr Paul McDaniel, the director of the division of research at the Atomic Energy Commission, explained that the AEC has embarked on a programme of machine building intended to replicate and to extend the work done in the Soviet Union with the Tokamak devices. Already, work is under way at the Oak Ridge National Laboratory and at the Princeton Plasma Physics Laboratory on the construction of two machines. Dr Robert Hirsch, the manager of the programme, told the Joint Committee that the Princeton project, involving the construction of a stellarator device, will cost $200,000 and "will duplicate the T3 plasma". The Oak Ridge machine will be similar to another Tokamak design except that the magnetic field will be produced by a one-turn coil so that asymmetry will be excluded. This machine should operate with a magnetic pressure twice that of its Russian analogue, so that there will be some hint as to how the scaling laws go and the magnetic coil will be easily replaceable so that it will be possible to check the influence of different parameters.

SPENDING ON PHYSICAL RESEARCH
(in thousands of dollars)

	1969 actual	1970 est.	1971 est.
High energy physics	118,630	120,530	119,450
Medium energy physics	11,266	12,790	13,140
Low energy physics	29,620	29,480	28,860
Mathematics and computer research	5,686	5,800	5,410
Chemistry research	54,482	53,970	51,980
Metallurgy and materials research	27,719	27,930	26,980
Controlled thermonuclear research	26,541	27,680	29,610
Total	273,944	278,180	274,430

Two other proposals which the AEC will follow include a machine at MIT (ALCATOR) which will allow magnetic fields of 130,000 gauss (four times that of the highest fields used in the Tokamak experiments) and an experimental device called Doublet II, intended for the Gulf General Atomic Corporation at San Diego. It also seems likely that the AEC will contribute to a proposal by the University of Texas, financed largely with $350,000 of university money.

Mr Hirsch went further than the long-standing promise of Dr Amasa S. Bishop, who has been in charge of the thermonuclear programme for the past four years but who is now succeeded by Professor Roy Gould, of the California Institute of Technology, that the feasibility of commercial nuclear power would be demonstrated by 1978, in saying that it would be apparent "sooner than 1978" that commercial thermonuclear power is feasible. "We now have several new tools in our hands. People of the CTR community think we are now at a point at which we can move forward at a steady pace." Even so, the AEC is not counting on the fashionable interest in laser research to help it towards this goal—although Mr McDaniel said that work was continuing on the use of laser light to irradiate specks of material, the ionized vapour of which would be contained in a conventional magnetic field configuration, it had already abandoned the notion that a thermonuclear machine might be constructed by a sequence of micro explosions triggered off by a laser.

Stretch Out for NASA

By now, it is clear that the total impact of the stringent budget under which the National Aeronautics and Space Administration labours will be a further postponement of some of the projects that had been advertised in the past few years. In evidence submitted to the Committee on Science and Astronautics of the House of Representatives two weeks ago, Dr John E. Naugle explained that the agency will in the coming year be taking steps to complete its plans for putting satellites in orbits about the Earth to practical use. At the same time, he was able to say that one of the objectives for the seventies "will be to understand the problems of the ecology of the Earth"—one of the ways of drawing attention to good intentions in the present climate.

In the year ahead, expenditure on scientific work and the applications of satellites will actually increase (if the budget is agreed) by about 50 per cent to $550 million. Physics and astronomy will be dealt with as in the current year, and will take roughly 20 per cent of the total. A somewhat larger sum will go on lunar and planetary exploration, although the total for this work will be rather less than in the current year. The bioscience programme and the bioscience satellites will be tapered off, but space applications will get more attention—and about $150 million—than in the past.

One of the projects for the year ahead is the construction of two advanced technology satellites (ATS F and G), to be launched respectively in 1973 and 1975. Each of these will weigh nearly a ton and one important innovation will be a steerable antenna beam which can be directed to within a tenth of a degree of any chosen point on the Earth. The satellites will also be equipped with lasers for communicating not merely with stations on the ground but with other satellites. One objective of the experiments will be to test the technology of air traffic control by satellite as well as to obtain information about the propagation of millimetre waves. The first of these satellites will be used for the cooperative programme in the broadcasting of television programmes that has been agreed with the Indian Government. For reasons of economy, Dr Naugle said, it has been necessary to delay the first of the launchings from 1972 to 1973 and the second from 1974 to 1975.

In the coming months, however, there will be a launching of the satellite called the Cooperative Applications Satellite in which an attempt will be made to track instrumented balloons from the satellite. This is a project in which American and French scientists will collaborate, with the French providing the spacecraft and the balloons but not the rocket. This experiment should provide some of the information on which decisions about the usefulness of satellites in aircraft control can be made.

On the use of satellites for geodetic purposes, Dr Naugle said that it is planned to launch a third satellite into an orbit inclined at 20° to the equator early in 1972. The objective here is to complement the results obtained with earlier satellites at higher inclinations, but it is also intended that there should be a radio altimeter for measuring directly the mean sea level of the ocean.

The use of Earth satellites for observation of the surface of the Earth is plainly dear to NASA's heart, although it seems not yet entirely clear how these possibilities will be exploited. One important part of the programme ahead is to make observations of the Earth from aircraft, although the photographs taken by the Apollo 9 astronauts seem to have given people plenty to chew over. In the year ahead, NASA is planning to continue with the design of two satellites intended to put into application some of the uses already suggested—the first of the two satellites should be launched in the first half of 1972. In meteorology, according to Dr Naugle, the most hopeful development has been the proof that instruments carried in satellites can usefully provide a record of temperature at all heights in the atmosphere, and this is the way in which NASA will put its chief emphasis.

In NASA's plans for the exploration of the solar system, the biggest development is a negative one—the decision to postpone from 1973 to 1975 the landing of a package of instruments on Mars. There will, however, be two Mariner spacecraft aimed at orbits about Mars in May 1971 (due to reach the planet in November). The first of these will be equipped to provide wide angle photographs of the surface of the planet, with a resolution of between 2 and 3 kilometres, for a period of about three months. The second satellite will be designed so as to make repeated observations of a few selected sites on the surface in a search for periodic phenomena (see page 995).

Dr Naugle explained to the House committee that the Viking project, "the largest single project" in the exploration of the solar system, is now at the point at which 165 proposed experiments have been whittled down to 25, selected last December. In the immediate future, work on the rocket will consist only of the development of those systems, concerned chiefly with landing and navigation, where progress is necessarily slow. It has, however, been decided that the rocket to Mars will be equipped with instruments to help select a good landing site, with instruments to determine the vertical profile of the martian atmosphere, to photograph the site, to analyse samples of surface material and also to seek out living forms as determined by photosynthesis and respiration. So far, there has been no postponement of the plan to launch a rocket towards Venus and Mercury in 1973. The chief object here is to learn something of the atmosphere of Mercury. The collaborative programme with West Germany to launch a rocket (Helios) to within the orbit of Mercury is also continuing. According to Dr Naugle, however, the most exciting of the projects now on hand is the launching of two Pioneer rockets towards Jupiter (page 996). The plan is that a prototype will be built and tested within the next year and that the completed rockets should be launched in March 1972 and April 1973 (each rocket will take just under two years to reach Jupiter).

Among the projects for the exploration of the region near the Earth, NASA has plainly great hopes for a number of orbiting observatories, both for the Sun and more distant objects in the universe. A great deal of what it plans to spend on this work will, however, go on the telescope package which is being designed for the Apollo applications programme.

SPACE STRATEGY

Almost a Blank Cheque

THE long awaited statement of government policy on space, made public last weekend by President Nixon, is not so much a declaration of purpose as a framework within which the National Aeronautics and Space Administration will be able to carry out most, although not quite all, of the schemes on which hearts have been set. To some, no doubt, it will be disappointing that the journey to Mars is described merely as a "longer range goal we should keep in mind as we proceed with our exploration of the planets". On the other hand, the President has made a firm commitment to the schemes for sending an unmanned rocket on a grand tour of the outer planets, using the gravitational field of one to help pave the way to the next—a trick which will be feasible in the late seventies but not thereafter until some time in the twenty-first century. One of the potentially most interesting features of the strategy now outlined is an undertaking to "encourage greater international cooperation in space".

The President's starting point last weekend was that "having completed that long stride into the future which has been our objective for the last decade, we must now define new goals which make sense for the seventies". He was anxious that the space programme should not stagnate but, at the same time, said "that we should not try to do everything at once".

The declaration of policy is said to be based on a consideration of the report of the space task group under Vice-President Agnew (see *Nature* **223**, 1297; 1969), and in practice it consists of an endorsement of most of the options there spelled out except the mission to Mars. The guiding principle, President Nixon says, was that the space programme should satisfy the hankering after exploration, that it should help to provide scientific understanding and, in particular, "should be attentive" to what scientists might suggest; third, that the space programme should exploit practical applications.

In practice, the President said that exploration of the Moon should continue even after the Apollo programme is completed, that there should be "bold exploration of the planets and the universe" with the grand tour as a starting point, an attempt to reduce the cost of space operations, which implies approval for the scheme to develop a space shuttle, an attempt to extend peoples' capacity to live and work in space, which implies approval for the experimental space station on which NASA is working, the increased applications of space technology in fields such as air traffic control and navigation as well as in meteorology and telecommunications, and the deliberate involvement of other countries than the United States.

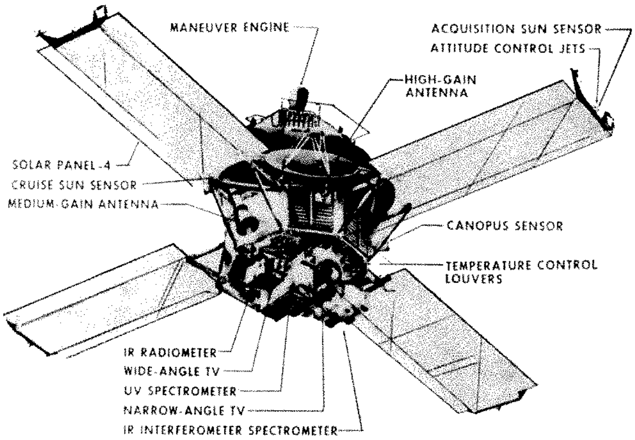
This declaration of policy will almost certainly imply that the budget of NASA will not in future shrink below $3,000 million a year. Indeed, as the space shuttle project moves from design to construction in 1972 and 1973 it may well be necessary to spend more on implementing the package which the President has put together.

To this extent, the new policy should provide NASA with a greater sense of security in the months ahead as well as with one or two exciting schemes on which to work.

PLANETS

Mars Progress Report

ONE reason why the plan to send two unmanned spacecraft into Mars orbit next year has not suffered in the wave of budget cuts is that it is based on the well-tried Mariner design whose most recent success was the close approach to Mars last summer. On the other hand, the more ambitious Viking project to soft-land two capsules on the surface of Mars has been postponed for two years from 1973 to 1975. The delay is expected to increase the $750 million cost of the Viking project by $150 million. Half of the increased expenditure will cover a rise in wages, and half the extra costs incurred by the less favourable position of Mars in 1975. Experiments for the Viking capsules and for the orbiting spacecraft from which they will be ejected were chosen last year (see *Nature*, **225**, 124; 1970), and none of the British proposals was selected.



The 1971 Mariner spacecraft.

The National Aeronautics and Space Administration has now published more details of next year's missions which will pave the way for Viking by identifying particularly interesting areas on Mars. Two spacecraft will be launched to reach Mars on November 14 (Mariner 8) and on November 24 (Mariner 9). The spacecraft are basically the same as the Mariners which achieved the close approach to Mars last summer, with the addition of a small engine to power the velocity change of 3,400 miles per hour for insertion into Mars orbit. Each spacecraft will weigh about 2,200 lb, which includes 970 lb of fuel. The 125 lb of scientific instrumentation on board will be made up of a 50 mm wide-angle television camera, and a 500 mm telephoto camera for detailed work, an infrared radiometer to measure surface temperatures, an ultraviolet spectrometer to identify the composition of the atmosphere, and an infrared interferometer spectrometer to look at constituents of the atmosphere and surface. Then there will be the usual close observations of the telemetry signals to improve estimates of various astronomical constants and for further information about the atmosphere of Mars.

The chief aim of Mariner 8 is to provide the maps of the surface which planetary astronomers badly need. It is already known that the density of cratering on Mars varies widely from place to place, for example, and good maps are essential for work on crater statistics. The plan is for the wide-angle television camera to cover the band between 40° north and 60° south with a resolution of two-thirds of a mile. The primary object of Mariner 9 is to search for changes in the appearance of surface features with time, in particular the wave of darkening which is visible from the Earth. Thus the Mariner 9 orbit will be such that the cameras can photograph the same area of the surface every fourth day.

GRAND TOUR

Planetary Billiards Approved

The preliminary exploration of the planets beyond Mars for which President Nixon has now given his approval fulfils at least two of the major recommendations made by the Space Science Board of the National Academy of Sciences in a report last year on the programme of exploration of the outer solar system (see *Nature*, **223**, 661; 1969). Among other things, the board urged that advantage be taken of a favourable configuration of the planets to dispatch probes to Pluto by way of Jupiter and Saturn in 1977, and to Neptune via Jupiter and Uranus in 1979. These proposals have now been agreed to. Coupled with flights to Jupiter alone, planned for 1972, the most urgent of the board's recommendations for the study of the outer planets in the 1970s will be carried out.

The reason for the haste is, of course, the once-in-a-lifetime opportunity of a particular alignment of the planets. The alignment, which will not recur for 180 years, allows the close approach to each planet to swing the probe on to the next with roughly the amount of power needed to reach Jupiter. Planning for the project, which has been going on at the Advanced Studies Office of the Jet Propulsion Laboratory, is based on a 1,200 lb spacecraft which could be launched by a Titan-Centaur rocket. Power for the spacecraft will probably come from a radioisotope thermoelectric generator, and clearly the spacecraft's appearance is going to be dominated by a large parabolic aerial for communications with Earth. With radio signals taking four hours to reach the Earth from Neptune, a new breed of spacecraft is going to be required with plenty of redundancy built into its circuits.

The justification for going to the outer planets is, of course, that without better knowledge, in particular of their constitution, it is difficult to theorize about the early history of the solar system, especially about the composition of the material from which the solar system condensed. It is not yet known what instruments the probes will carry, but the payload will probably include cameras, ultraviolet and infrared detectors for studying planetary atmospheres, and radiation detectors. It will also be important to take full advantage of the spacecraft to probe the interplanetary medium, and one problem may be to ensure that it remains magnetically clean after passing through the Jovian field. There is also the question of designing instruments which will not be ruined by the adverse conditions expected near Jupiter—a high flux of energetic particles, and possibly dust clouds. Another problem is whether the spacecraft should be complicated by the addition of entry probes to study planetary atmospheres.

It is clear that these are not going to be missions with quick results. It will take seven or eight years to reach Pluto, for example, but this is better than the 41 years which a direct flight would involve. Neptune will take 8·9 years, compared with 18 years by direct flight, and Jupiter (which will be the most important planet for the missions) will be reached after just under two years.

MEDICAL RESEARCH

Good Fairy for the NIH

The National Institutes of Health have fared best among the scientifically oriented agencies of the United States Government out of the new budget (see *Nature*, **225**, 582; 1970), and now seem like also to profit from the way in which Congress has forced the Administration to accept a somewhat larger budget for the Department of Health, Education and Welfare than is welcome. Although it is not finally certain that the President will refrain from vetoing the legislation giving spending authority for the current year's budget, the chances are that the National Institutes of Health will finish up more than $10 million better off than they had hoped. This should allow a little relief from the present pressures on the budget even if the extra money is likely to be chopped off the budget for the year which begins in July, when the National Institutes of Health as a whole are hoping to grow by $66 million to $1,526 million for the year.

Among the operations of the National Institutes of Health, the National Cancer Institute and the National Heart and Lung Institute will grow most steadily, at least if the budget gets through Congress unscathed, the former by $29 million to $201 million and the second by $19 million to $171 million. A less spectacular beneficiary of this now unfamiliar open-handedness is the National Institute of Dental Research, which has an extra $6 million in the new budget. The parts of the NIH programme which have grown like this are related in one way or another to the Administration's hope that it will be possible to put paid to a number of social problems by careful spending on health research. It remains a remarkable feature of the NIH budget, however, that it has turned out to be possible to sustain, although not increase, the amount of money which the NIH will be able to commit to educational activities. Other agencies have found themselves forced to abandon or severely curtail educational programmes—the National Science Foundation's traineeship programme and the NASA University Sustaining Programme are among the more spectacular casualties (see page 985). It appears that the NIH have been able

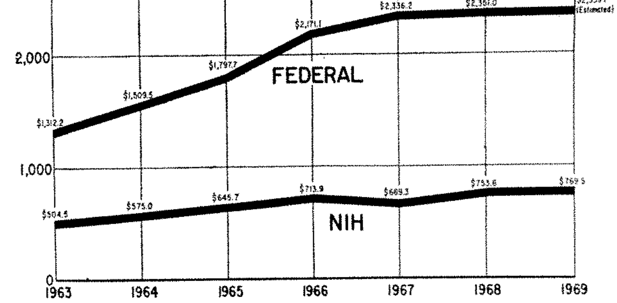


Fig. 1. Federal and NIH support for academic science, including both research support and finance for students and training programmes.

to keep their own educational programmes intact by vigorously complaining that curtailment would reduce the numbers of trained doctors at a time when shortages already serious are likely to become even more apparent.

Although the budget of the NIH as a whole has continued to grow over the years, the direct benefit to research and to universities has tended to stagnate for several years. Thus the total amount to be spent on research grants if the new ship comes home will be $546 million, nearly £10 million less than two years ago. Much of the increase to be expected will be spent on what is called collaborative research and development, chiefly by letting contracts. (An extra $50 million is earmarked for this purpose, while the cost of research carried out at the national institutes themselves will increase by merely $10 million.) With the sustained growth of the NIH since the early sixties, contracts have played an increasingly important part in the pattern of research financing, not merely no doubt because there are limits to the work which can be done by a necessarily limited group of people, but also because there is more scope for this method of working in circumstances when research programmes are aimed at specific goals.

EDUCATION

New Plans for Students

URGED on by the ubiquitous Mr Daniel P. Moynihan, who has been in hot water in the past few days for suggesting in a private memorandum that the colour problem would profit from a period of "benign neglect", President Nixon announced last week a programme intended to improve the quality of education in American schools. One important development is the setting up of a National Institute of Education intended to carry out and to sponsor educational research to the tune of as much as $250 million a year. There is also a Commission on School Finance to study the financial problems of the school system, public and otherwise. In the hope of replacing some of the welfare projects of the last Administration, Project Headstart in particular, by more effective programmes, President Nixon has also suggested a programme of financial assistance, costing $200 million in the year ahead, to help states and local communities teach children to read and there is to be another programme of what are called "child development projects".

The National Institute of Education is plainly destined to become the focus for most kinds of federally sponsored educational research in the United States. Much of its work will be concerned with curriculum development and with the evaluation of new kinds of curricula. Much of the work will be undertaken by universities and other organizations under contract, but it is intended that there should be a National Advisory Council to guide the development of policy. Among the particular subjects mentioned in the message to Congress on March 3 were the search for more effective means of "compensatory education", the search for new methods of putting flesh on the bones of Dr James E. Allen's slogan "Right to Read", partly by helping school libraries to buy books and by helping school systems provide special teaching programmes, and the investigation of the use of television in education.

One of the oddest features of this proposal is that it now seems somewhat old fashioned. Ten years ago, curriculum development was all the rage and programmes such as that of the Physical Sciences Study Committee were widely acclaimed. More recently, in the mid-sixties, there seemed to be great enthusiasm for the application of television and management techniques to the learning situation. In the past few years, however, much of the enthusiasm for these programmes seems to have been turned in other directions, as if the first wave of really self-conscious curriculum development had been diffused into the practical problems of how best to organize the application of the new techniques, still far from complete—a tendency no doubt accelerated by the shortage of funds in the educational budget. The efforts of the National Science Foundation in this direction have been shrinking for the past few years. Although the Administration is now plainly concerned with a different part of the educational system from that in which curriculum development began in the nineteen fifties, the success of the National Institute of Education will plainly be intimately dependent on the chance that able people are ready to participate.

The proposals for helping with the analysis of the financial plight of school systems, through a commission already appointed, are still somewhat an unknown quantity. At present, states are responsible for 38 per cent of the cost of operating school systems, and 54 per cent of the cost is met from local funds. The federal sources provide only 8 per cent. One of the problems to be tackled is to find some way of channelling more federal money into the school systems, but there have already been complaints that President Nixon's promise to make a study does not do away with the urgent need for financial assistance to prevent some school systems from collapsing altogether. The fact that the United States spends more on education than the rest of the world put together, according to President Nixon's statement, may not be a sufficient guarantee of health. On the other hand, it seems to be agreed that there will be great profit if great uncertainty in some of the schemes that are being talked about for helping to improve the educational environment of those not yet at school.

ECLIPSE

Observations Galore

THE solar eclipse last Saturday was a great success and, if these things were regulated by the wishes of astronomers and even of the general public, there would evidently be more of them. In Mexico, the 300 observational astronomers who had gathered for the occasion were provided with almost perfect conditions for observing the eclipse. As the track crossed Florida and the coast of Georgia, clouds obscured the view, but as it reached the cleverly sited station of the National Aeronautics and Space Administration at Langley air force base and Wallops Island in Virginia, conditions could not have been improved on. At Langley air force base, photography of the flash spectrum of the chromosphere is said to have been successful. At Wallops Island, the staff managed somehow to launch 31 sounding rockets before, during and after the total eclipse. The only failure was the loss of a naval research laboratory payload intended to return flash spectra of the chromosphere in the ultraviolet—the Aerobee rocket functioned perfectly but the payload disappeared. One of the Nike-Cajun rockets intended for ozone measurement also failed to function, while the second of two airglow experiments was cancelled when the first failed.

In these circumstances, the star turn at Wallops Island was the international experiment involving teams from Imperial College, London, the Culham Laboratory of the UK Atomic Energy Authority, Harvard University and York University, Toronto. Dr R. J. Speer, of Imperial College, said after recovery of the film package that he and his colleagues had been surprised and delighted by the quality of the films recovered. He explained that the experiment was designed to provide ultraviolet spectra of the Sun at three-second intervals in two ranges from 85 to 200 nanometres and from 210 to 310 nanometres. In practice, Dr Speer said, the rocket had functioned perfectly and the apogee had been placed accurately within the ten kilometre cube at the instant of totality. The package of film recovered was found to include fifty complete spectra, only slightly fogged, representing the ultraviolet output of the Sun at intervals of three seconds of time between each of which the Moon had moved 1·3 seconds of arc. Since the chromosphere is about 10 seconds of arc thick, the sequences of films will make it possible to reconstruct the ultraviolet emission of the chromosphere in great detail.

Dr Speer was full of praise for the way in which the rocket operation had been mounted and the equipment itself had performed. He said that this was the first occasion on which the guidance system has been flown—the principle is to lock on to the nearly eclipsed Sun and then to follow with inertial guidance during totality. By good chance, it seems, the rocket happened to be stationary at the point of the second contact, which means that the interpretation of these photographs will be simplified. Dr Speer also praised the way in which an expeditious recovery of the package made it possible to start work on development of the spectra in just over five hours after the eclipse—an important consideration with ultraviolet sensitive film in which the sensitive grains lie on the surface and are easily damaged.

COLLEGE ADMINISTRATION

Scientists as Presidents

Two distinguished scientists will in future be presidents of two colleges which have been more than a little disturbed by the troubles of the past two years. The most unexpected appointment is that of Dr Robert E. Marshak, the theoretical physicist from the University of Rochester, who has been appointed president of City College, New York. Dr Marshak, who is 53, began his research career at Cornell, where he worked with Bethe on thermonuclear reactions in stars, among other things, but has been at the University of Rochester since 1938 and has worked on the penetrating components of cosmic rays. In the past few years, he has been an outspoken critic of university administrations for their unwillingness to admit students into full participation in university government and in this spirit he resigned from the faculty senate of the University of Rochester as recently as February 13. He said after his appointment on February 27 that he proposed delegating a good deal of the administration of the City College, which has some 20,000 students, to a provost yet to be appointed and that he would try to sponsor ways in which the university could help with the social improvement of depressed parts of the city.

Dartmouth College, New Hampshire, is a somewhat more sedate institution, even though there was some trouble there some years ago. The new president is Dr John G. Kemeny, professor of mathematics and philosophy at Dartmouth for the past fifteen years. Dr Kemeny, a Hungarian by birth, has been much involved in the development of time sharing computers.

YOUNG SCIENTISTS

More Scholarships for Precocity

Like an intellectual version of the Miss America competition, the twenty-ninth search for talent among budding scientists in United States high schools ended successfully last week with the presentation of awards ranging from $4,000 to $10,000 to ten young people between fifteen and seventeen, two of them girls. A large roomful of people, described by Dr Glen Seaborg, chairman of the Atomic Energy Commission, as "everybody who is anybody in science", shared with the thirty unsuccessful finalists in the room the sight of the winners being called to the limelight in reverse order, $4,000 people first and the $10,000 winner, Kirk A. Shinsky of Allentown, Pennsylvania, last of all. The occasion was a great success for New York, the state which provided seven out of the ten winners. The Bronk High School for Science produced no fewer than three of these.

The annual Science Talent Search is organized by Science Services but financed by the Westinghouse Corporation. Mrs Dorothy Shriver, an assistant director of Science Services responsible for the organization of the programme, said there were this year almost 3,000 initial applications from high school students. Applicants provide a written account of a scientific project which is then supplemented by information from teachers and by a "scientific aptitude test". Mrs Shriver explained this week that this test will in future be replaced by the scores obtained in the national scholastic aptitude tests, chiefly because experience has shown that there is very little difference between the two yardsticks of performance even though the test which has in past years been designed for the talent search has consisted almost entirely of scientific questions.

The 3,000 applicants were this year winnowed down to 300, the dossiers of whom were rescrutinized so as to produce a short-list of 40 young people who then spent a week in Washington seeing some sights and some dignitaries. The ten winners were chosen by the seven judges after personal interview. Mrs Shriver says that the judges are more concerned with promise than achievement, but she acknowledges that it is necessarily hard to distinguish between scientific aptitude and general intelligence. Four years ago, a twenty-five year follow-up study among the people who had been the first winners suggested that ninety per cent had gone on to take higher degrees and that seventy per cent had remained in science.

NEWS AND VIEWS

Towards Hybrid Plant Cells

BOTANISTS are lucky that they can do with an easy conscience things that bring down the wrath of public opinion on their zoological colleagues. Professor Cocking and his co-workers at Nottingham, who this week report the first successful steps towards cell fusion in plants (page 1016), can expect unalloyed admiration and gratitude for their labours. They may have laid the foundations for a vast new programme of genetic engineering, but even the sternest guardian of morals must welcome the eventual development of new and better varieties of crop plants, and is unlikely to object to any monster plants that may be produced in the meantime.

The achievement of the team in Nottingham has been to release the contents of plant cells from their hard retaining walls, and to induce the resulting cytoplasmic masses, known as protoplasts, to fuse together in pairs. Although this has been done before, fusion has not been reproducible as it is now, and protoplasts were obtained by mechanical manipulation, far less sophisticated than Cocking's precisely defined mixture of enzymes. The most significant factor for plant breeders is that fusion has now been achieved between protoplasts from different species.

Of course, this does not mean that a hybrid plant cell has been produced in the laboratory, for there is yet no sign of fusion of the nuclei contained in the fused protoplasts. And even when that has been achieved it will still be necessary to generate a new cell wall around the fused protoplasts. At present there is no indication as to when these vital steps will be taken, but it is certain that no efforts will be spared to hasten the day.

When the day comes, the interest of geneticists will focus principally on fusion between plants such as Cocking *et al.* have been using—oats, maize and barley—which cannot be hybridized in field or greenhouse by conventional methods. Once hybrid cells are ready there should be little difficulty in growing them into mature plants, for there is a vast store of knowledge, gathered all over the world, about the conditions required to induce single plant cells to differentiate and develop in the same way as a normal embryo within a seed.

Just as disease resistance can be introduced into wheat from other species, so there are hopes that, starting with the techniques developed by Cocking and others, it will be possible to endow maize, barley and oats, for example, with useful characters from species with which they cannot be mated successfully.

The returns from such work would be slow to come, as they always are with plant breeding, but they would certainly be significant from the point of view of world agriculture. Further progress in plant cell fusion will undoubtedly be awaited eagerly. There may be much to be learned from the zoologists who have already fused mammalian cells successfully although they are in no position to grow their hybrid cells into mature animals, for which most people are thankful. On the other hand, it might be said to be the social responsibility of Professor Cocking and his colleagues to continue with their work as quickly as possible.

Starts, Stops and Anti-stops

THE outsider must find it a great consolation that the concepts of molecular biology are a great deal simpler than the language, or rather shorthand, the professionals use to communicate them. Current ideas about the positive control of the process of genetic transcription, copying genetic information from DNA to RNA, for example, are much simpler than a glance at the reports by Travers (page 1009) and Bautz's group (page 1012) might suggest. It is little more than a year since these two groups, working at Harvard and Rutgers Universities, reported in *Nature* (**221**, 43; 1969) the discovery of the so-called sigma factor, a protein in *E. coli* which transiently associates with the enzyme RNA polymerase and confers on it the ability to discriminate between genes. Sigma factor in effect tells RNA polymerase which genes it can copy and so exerts positive control over genetic expression. Since the discovery of the *E. coli* sigma factor, several analogous factors made by bacteriophages have been discovered, and we now have a fairly detailed picture of the involvement of sigma factors in the replication of T4 coliphage.

Immediately after an *E. coli* cell has been infected with T4 DNA the bacterial RNA polymerase programmed by the *E. coli* sigma factor starts to copy phage RNA from a set of so-called pre-early phage genes. Travers has shown that one of these genes specifies a new phage specific sigma factor. Once made, this displaces, by a completely obscure mechanism, the *E. coli* sigma. As a result the RNA polymerase is subverted to copying phage instead of *E. coli* genes and the replication of the phage continues at the expense of the host bacterium. At some later stage in the replication cycle, either a second phage specific sigma factor is made, or the first phage sigma and the host core RNA polymerase are modified to permit expression of more so-called late phage genes. Details of how this change is achieved are, however, obscure.

Sigma factors dictate the specificity of the start of RNA synthesis, but what signal tells the enzyme where to stop synthesis ? If sigma factors act as capital letters, what are the full stops ? Last year Roberts reported from Harvard (*Nature*, **224**, 1168; 1969) the discovery of another factor, rho, which somehow tells an RNA polymerase molecule it has reached the end of a particular unit of genetic information and should stop making RNA. In theory, sigma and rho factors working together could provide a complete positive control mechanism to regulate sequential gene expression. Bautz and his colleagues (see page 1012), however, suggest that there may be more to the process than that. Like Travers, but less directly, they find that T4 sigma factor allows the polymerase to read genes which cannot be read if the enzyme is programmed by *E. coli* sigma. But they also find that some T4 genes are read very early in infection even though they are expressed as proteins only late in infection when all the *E. coli* sigma factor has disappeared. They suggest that this very early reading of late genes occurs because of a failure in the normal termination process. They envisage that at the outset of infection *E. coli* sigma and polymerase initiate the synthesis of the first phage RNAs to be made. These include, of course, the RNA specifying the T4 sigma factor. But instead of stopping RNA synthesis at the correct points the enzyme sometimes reads through the earliest genes and goes on to copy into RNA some of the genes expressed much later in infection when the T4 sigma is active. Such read-through must be the result of a failure in the *E. coli* termination mechanism; rho cannot be functioning properly. Bautz *et al.* suggest that one of the first phage proteins to be made together with the phage sigma is an anti-terminator which somehow stops the terminator, rho, from acting. To prove their point they must now isolate the putative anti-terminator.

GALAXIES

Ejected Clouds in Milky Way

from our Cosmology Correspondent

THERE is now increasing evidence that the centre of our own galaxy has at some time been the site of violent events comparable with those seen in Seyfert galaxies. The latest addition to this evidence comes from a survey of the high velocity component of the 21 cm profiles seen in the region $10° < l < 350°$, $-5° < b < +5°$ which has been carried out by P. C. Van der Kruit using the 25 m telescope at Dwingeloo (*Astron. Astrophys.*, **4**, 462; 1970). Van der Kruit has observed many of the well known features which lie in the galactic plane, but features which are not associated with the structure of the plane are all found to have velocities greater than would be expected from the rotation of the galaxy.

Almost all the material is expanding away from the nucleus, except for that in the nuclear disk, which is rotating very rapidly. At negative longitudes these features are seen above the galactic plane, and at positive longitudes below it, suggesting that clouds have been ejected from the nucleus in two roughly opposite directions, at an angle to the plane which may be the same as that of the secondary ridge of continuum radiation found by Kerr and Sinclair (*Nature*, **212**, 166; 1966). Van der Kruit favours the idea that this matter has been ejected rather than that it is falling into the nucleus, and suggests that the energy in the required explosions would be as large as 10^{57} ergs, comparable with that seen in radio galaxies, and that they occurred 10^7 years ago. Many of the features of the ejected clouds can be explained satisfactorily in terms of the clouds seen emitted from Seyfert galaxies, provided that it is accepted that in our own galaxy the clouds have had time to expand to diameters about an order of magnitude larger than the clouds in Seyfert galaxies, with corresponding reduction in their outward velocities and temperatures.

Following the observations in the far infrared which support the hypothesis that the nucleus of our galaxy is similar to those of Seyfert galaxies (E. E. Becklin and G. Neugebauer (*Astrophys. J. Lett.*, **157**, L31; 1969) this evidence at radio wavelengths does much to encourage the idea that all galaxies pass through such an active stage in their evolution.

NUCLEAR MAGNETIC RESONANCE

In the Crystal Ball

from our Molecular Biology Correspondent

ANYONE wishing to lay a modest bet on scientific trends for the seventies might do well to give a thought to ^{13}C nuclear magnetic resonance of biological molecules. The first few cautious exploratory offerings in the literature may amount as yet to a cloud on the horizon no bigger than a man's hand, but the prospects are clear enough. In the first place, the chemical shifts are very much larger than for protons, and the possibilities for assignment and resolution of resonances are correspondingly greater. Second, the use of ^{13}C should make it possible to extend the method to macromolecules of much greater size than is feasible for proton resonance, and finally it has been demonstrated that there are good prospects of working on native materials, taking advantage of the natural abundance of the ^{13}C isotope.

This feature, which may in many cases eliminate the limitations and tedium of preparation of ^{13}C-labelled materials, is brought out in two articles that explore the ^{13}C-resonance spectra of natural nucleotides. Dorman and Roberts (*Proc. US Nat. Acad. Sci.*, **65**, 19; 1970) have examined a series of nucleotides in aqueous solution. Simply by means of comparisons of different sugars and pyrimidines, all the sugar and pyrimidine carbon resonances can be assigned; purine frequencies are assigned, at least in part, with the aid of procedures (heteronuclear decoupling) which make it possible to establish whether protons are attached to the nuclei from which particular resonances arise. The ^{13}C spectra of the common nucleosides have been analysed in an accompanying article by Jones *et al.* (*ibid.*, 27), which supports and completes the assignments, and emphasizes the remarkable degree of discrimination between carbon nuclei in only slightly different environments.

Another exploratory study, this time on amino-acids and some peptides, comes from Horsley, Sternlicht and Cohen (*J. Amer. Chem. Soc.*, **92**, 680; 1970). The materials were prepared from cultures of algae grown from a ^{13}C-enriched source. The chemical shifts are again many times greater than those for protons. It is well established that the chemical shift of a ^{13}C frequency can be derived in terms of the nature of the carbon skeleton, with quantitatively defined values for the α-carbon, β-carbon and so on as far as the ϵ-position, when a proton on the α-carbon is replaced by a methyl group. By this means, and by comparison of the different amino-acids, Horsley *et al.* have made an essentially complete assignment of the entire spectrum. It has already been shown that there are small but measurable sequence-dependent differences in frequency in peptides, and Horsley *et al.* envisage the likelihood that peptide carbonyl resonances of proteins will reflect the local chain conformation. One now awaits ^{13}C resonance studies on enzymes.

A different use of an isotope in NMR has the aim of clearing the thicket of the proton magnetic resonance spectrum of proteins, so as to focus on selected residues only. If an enzyme is prepared from cells supplied with selected deuterated amino-acids, the number of proton resonances in the spectrum can be reduced at will. This method has been applied to staphylococcal nuclease by Putter *et al.* (*Proc. US Nat. Acad. Sci.*, **64**, 1396; 1969). Five derivatives, containing protons only in two, three or four species of amino-acid, were prepared. With the tryptophan residues deuterated, the aromatic region of the spectrum emerges starkly simple from the mush of overlapping bands present in the native enzyme. The tyrosine and histidine frequencies can be identified easily. The aliphatic region is also much simpler, and, for example, four peaks apparently corresponding to the methyl groups of the four methionine residues are resolved. The twenty-three lysines, with their many protons, remain difficult to disentangle, however, and it would require chemical synthesis or hybridization of non-covalently associating fragments from deuterated and undeuterated molecules to make any further impression. To the fertile mind many applications of selective deuteration will suggest themselves.

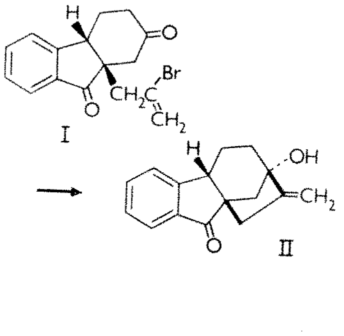
CHEMICAL SYNTHESIS

New Cyclization Reactions

from our Organic Chemistry Correspondent

THE formation of a new carbon–carbon bond by reaction between a Grignard reagent and a carbonyl compound is well known. But although this reaction can be utilized to bring about efficient coupling between two molecules, no effective intramolecular counterpart has been developed.

A practical solution to this problem has now been found which utilizes the organo-copper species di-*n*-butylcopperlithium (Corey *et al.*, *J. Amer. Chem. Soc.*, **92**, 395, 396; 1970). This reagent attacks a vinyl bromide or iodide more readily than it does an isolated ketone function. The possibility of effecting cyclization when both functions are present in the same molecule is exemplified by the conversion, in high yield, of the bromodiketone (I) into the keto-alcohol (II), which has the carbon skeleton of the plant hormone gibberellic acid. Cyclization proceeds selectively to give the desired new five-membered ring; protection of the second carbonyl group is unnecessary.



Similar cyclizations can be carried out with saturated haloketones, but yields are disappointing (about 20–30 per cent). An alternative procedure, also reported by Corey *et al.*, however, overcomes this difficulty. The reagent of choice is now the dianion derived from nickel tetraphenylporphine and two equivalents of lithium naphthalene. With this, in tetrahydrofuran, 7-iodo-2-heptanone is cyclized to 1-methylcyclohexanol in 88 per cent yield. A detailed mechanistic picture of these valuable new transformations, however, is not yet clear.

MÖSSBAUER EFFECT

Liquid Crystals Join the Club

THE latest surprise to emerge from the select group of materials known as liquid crystals is an observation of the Mössbauer effect in a smectic liquid crystal. D. L. Ulrich, J. M. Wilson and W. A. Resch (*Phys. Rev. Lett.*, **24**, 355; 1970) have introduced atoms of ^{57}Fe into a smectic liquid crystal with a low solid to smectic transition temperature and have obtained the familiar shapes of Mössbauer spectra produced through the recoil-free emission of gamma rays from the unstable ion.

This experiment opens up a valuable new way of studying liquid crystals. The peculiarity of these materials is, of course, that the long rod-like molecules have some of the translational and rotational degrees of freedom of a liquid and yet retain a kind of crystalline order in the manner of a solid. What is interesting is that for the Mössbauer effect to occur there must be strong binding between atoms to provide the recoilless emission of low energy gamma rays, and it seems that the layered structure of the smectic liquid crystal is rigid enough for this to happen. In normal liquids the atomic binding is, of course, too weak, but the Mössbauer effect has been demonstrated in glycerine, the high viscosity of which is thought to be due to hydrogen bonding. There is no evidence, however, of hydrogen bonding in liquid crystal systems.

Ulrich *et al.* observed the changes in Mössbauer spectra as a sample was taken through two phase transitions, solid to smectic liquid crystal and smectic to nematic liquid crystal. An abrupt reduction in peak heights was seen at the first transition and at the second the Mössbauer effect vanished completely as the molecules gained an additional degree of translational freedom. The ^{57}Fe atoms had been introduced to the system through a small quantity of solute. The effect of the liquid crystal in aligning the solute molecules was evident from the changes in symmetry of the spectrum when the sample was shaken and then taken through a heating and cooling cycle.

The Mössbauer effect has been steadily finding new applications since its discovery in 1958. During the past six or seven years a mass of information has been accumulated on hyperfine interactions, and more recently several industrial applications have been gaining a hold. The presence of different phases can be recognized by the superimposition of spectra; for example, in supposedly aluminium doped yttrium iron garnet (YIG) the presence of a precipitate of pure YIG can be recognized from the Mössbauer spectrum. The determination of the ferrous to ferric ratio in sintered iron ore mixtures is being used to estimate the optimum conditions for operating blast furnaces, and at the Atomic Energy Research Establishment at Harwell Mössbauer spectroscopy has proved a valuable tool in the production of a series of aluminium garnets.

EXTRA-OPTICAL ASTRONOMY

X-ray and Microwave Progress

from our Cosmology Correspondent

REASONABLY accurate measures of the positions of X-ray sources are in most cases essential before any identification of the object with an optical or radio source can be attempted. It is therefore particularly welcome that W. Mayer, H. V. Bradt and S. Rappaport have determined fairly good positions for twelve X-ray sources, all lying in the intensity range 1·5–8 keV, and all observed on the same rocket flight on July 26, 1968.

By making a rapid sequence of still stellar photographs, the orientation of the rocket was recorded at any time in the flight, and the accuracy of the alignment is confirmed by the detection of the well known source Sco X-1 with a position error of less than 2′·5 (*Astrophys. J. Lett.*, **159**, L115; 1970). For each of these twelve objects, the positions given by Mayer *et al.* are better than those previously known, in some cases considerably so. But none of the sources seem to exhibit the irregular variation seen in some of the more closely studied sources, such as Sco X-1, because the observed intensities on this flight are roughly comparable with those seen several years before.

In the same issue of *Astrophys. J. Lett.* (**159**, L123; 1970) comes news of improved information about the other important class of new objects recently detected as a result of the expansion of astronomy either side of the optical range. P. R. Schwartz and A. M. Barrett have surveyed 134 infrared sources in a search for microwave H_2O emission, and have found this in three new sources, NML Cygni, V Herculis and W Hydrae. Two of these three stars are long period variables, as is becoming almost standard in such cases, but there are considerable differences between their other properties, both at microwave and infrared wavelengths. VY Canis Majoris and R Aquilae, previously known H_2O sources, were also studied. Like V Herculis (a Mira variable) and W Hydrae (a semi-regular variable) R Aquilae varies in intensity, although in detail its spectrum is unlike those of each of the other variables. Perhaps the most important similarity is that in each case the radial velocities of the radio H_2O lines lie between the radial velocities of the H_2O emission and absorption lines at visual wavelengths, although closer to that of the visual absorption line. Although this offers a hint as to the details of the maser action producing these lines, no entirely satisfactory model of these sources is likely to emerge until more intensive studies of the stars have been carried out.

CARBON FIBRES

Fine Structures in Ribbons

from our Materials Science Correspondent

THE results of an intensive programme of research into the detailed structure of high strength carbon fibres, in progress for the past three years in the laboratories of Union Carbide Research Associates in Brussels, have been summarized recently by Fourdeux, Hérinckx, Perret and Ruland (*CR Acad. Sci.*, **269**, 1597; 1969). Most of their work was done with 'Thornel' fibres, made from cellulose by Union Carbide, but studies carried out elsewhere on fibres made by the British process from polyacrylonitrile (PAN) have shown that both types of fibre have very similar structures. Techniques used included X-ray and electron diffraction, small-angle X-ray scattering, electron microscopy and potassium intercalation.

The conclusion is that high strength carbon fibres consist of two dimensional ribbons of trigonally bonded carbon sheets, highly oriented but somewhat twisted, with long, narrow, lens-shaped cavities making up between 5 and 30 per cent of the total volume, and entirely isolated from each other. The carbon ribbons form very shallow parallel stacks between 30 Å and 100 Å thick. This, however, does not imply that even within these slender stacks the individual layers are put together in a graphitic stacking sequence: the structure is parallel but in arbitrary azimuth, properly described as turbostatic. The fact that the fibres are able to form a complete sequence of potassium intercalation compounds in spite of the highly irregular structure is taken by Fourdeux *et al.* as evidence that there are essentially no cross-links between adjacent layers and specifically that no sp^3 carbon atoms are present. Presumably, because parallel stacks do form, they must be held together by weak van der Waals bonds.

The conclusion that cross-links are absent is parallel to the view taken by Halpin and Jenkins (*Proc. Roy. Soc.*, A, **313**, 421; 1969) with respect to vitreous carbon, which is made in the same way as fibres by pyrolysis of polymers. Halpin and Jenkins reached their conclusion on the basis of the ready formation of potassium intercalation compounds. Fibres and vitreous carbon thus differ only in the presence or absence of preferred orientation of the *c* axis, and (possibly) in the presence of cavities in fibres. Nothing seems to be known about the presence or absence of cavities in vitreous carbon. Fourdeux and her colleagues point out that carbon fibres are wholly non-graphitic (as is vitreous carbon) and that the references in the literature to "graphitizing temperatures" should be taken as metaphorical.

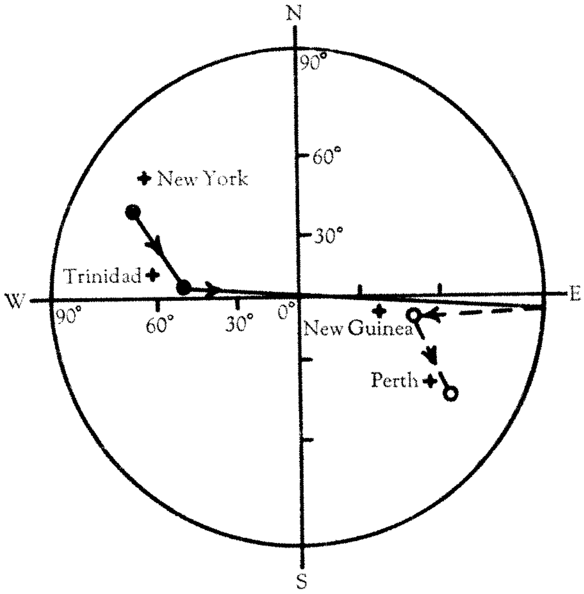
Another approach to the problem, using the time-of-flight neutron diffraction technique, has been taken by Sinclair, Wedgwood, Harris and Egelstaff (UKAEA Report, AERE-R 6052, HMSO, 1969). Using Harwell (PAN) fibres, they, too, found a stack thickness of 100 Å down to less than 50 Å, depending on the mode of manufacture, with alignment as good as 3°–4° (again in agreement with the best Union Carbide results). Attempts to detect cavities by small-angle neutron scattering have so far been vitiated by parasitic scattering from other sources. Sinclair *et al.* regard the technique as sufficiently promising to warrant further experiments.

PALAEOMAGNETISM

Another Transition Zone

from our Geomagnetism Correspondent

One of the classic pieces of evidence for reversals of the Earth's magnetic field is the existence of transition zones—sets of rocks apparently magnetized when the field was actually reversing from one polarity to the other. Unfortunately, the time the field spends in the process of reversing is but a few per cent of the time spent in the fully normal or reversed states, which is why only a handful of well defined transition zones have been recorded.



The migration of the ancient geomagnetic pole from normal to reversed states, as determined from Indian sediments.

A newly discovered transition zone is thus good news for palaeomagnetists in general and proponents of field reversal in particular. Such a zone has now been reported by Pullaiah and Verma (*Phys. Earth Planet. Interiors*, **2**, 158; 1970) in the Tirupati sandstone formation (Lower to Middle Cretaceous) from Godavary Valley, India. To be sure, there are only two samples within the transition zone proper, which means that the new zone is not the best known example. On the other hand, the stability of the magnetizations of the two samples has been studied in great detail, which cannot be said of some of those transition zones discovered when palaeomagnetism was in its infancy. Thermal and a.f. demagnetization thus leave no doubts that the observed magnetizations are primary; and petrographic examination revealed no evidence of mineralogical differences between normal and reversed samples, and thus no hint of self-reversal.

PLASMAS

Instabilities in the Solar Wind

from our Magnetosphere Correspondent

An outstanding problem in dealing with the solar wind concerns the temperatures of the electrons and protons, which are observed to differ considerably (electrons are hotter by a factor of about 2·5), but not as much as they would according to the crude theoretical model. The plasma is cooled by adiabatic expansion as it flows away from the Sun, and thermal conduction which is important is much more effective for electrons than protons. Collisions are barely important and so the standard transport coefficients are of dubious validity, a conclusion which also follows the fact that the thermal velocity of the electrons exceeds the wind speed, while the proton thermal velocity does not. Collisions are insufficiently frequent to make the temperature isotropic, and the anisotropy is aligned with the magnetic field.

It seems that heat must be transferred from the electrons to the protons by means of some unstable waves, since the collisional transfer is negligible, and this is confirmed by the observed ratio of temperatures. Such a transfer reduces the temperature gradient of the protons and increases that of the electrons. Forslund (*J. Geophys. Res.*, **75**, 17; 1970) has shown that heat conduction in the electrons is itself a source of instability for several plasma wave modes. Associated with the heat flow is a skewing of the proton and electron distribution function (integrated over $v_\perp$ to give a reduced distribution over $v_\parallel$). The outgoing electrons have a bigger velocity spread than those ingoing and consequently the peak of the distribution occurs at a lower outward velocity than the mean velocity. If there is no electric current, the mean velocity of the protons is the same as that of the electrons, and then the peaks of the proton and electron distributions are separated and waves may be amplified in essentially the same way as when a current flows in a plasma of uniform temperature.

Forslund estimates growth rates for the various modes at various distances from the Sun. Ion acoustic waves have high growth rates and the magnetic field is weak enough to be neglected here, but the waves are damped if the temperature ratio approaches unity. They probably start at ten solar radii and dominate until the temperature ratio drops to the critical value. The resulting heating of the protons occurs in the tail of the proton distribution.

Where the temperature ratio is not large other modes involving the magnetic field may be important, and their stability depends also on β, the ratio of plasma pressure to magnetic pressure, which increases with distance from the Sun. The first to go unstable may be the less familiar electrostatic ion cyclotron mode, the growth rate of which is also proportional to $\partial f/\partial v_\parallel$ at the parallel phase velocity. These waves may heat the protons a little farther out by gyroresonance. Far out, at about one astronomical unit where β is high, the fast magneto-acoustic mode may be amplified at frequencies near the proton gyrofrequency. The stability condition is complicated by the importance of the magnetic force. More general electromagnetic waves, the stability of which depends on cyclotron harmonic resonances, should also be considered.

A quantitative quasilinear treatment of the energy transfer remains to be carried out and it may well be necessary to use a more detailed model of the distribution, but the way seems clear for the construction of an adequate theoretical model. It is already clear that macroscopically the rate of heat transfer from electrons to protons increases with the magnitude of the electron temperature gradient and this could have interesting dynamic effects.

SOLID STATE

Electroluminescent Devices

from a Correspondent

In twenty years the transistor has almost ousted the simple electronic vacuum tube and a similar usurpation may be facing the cathode ray tube. Although such a development would take at least twenty years, devices for producing the visual effect are becoming commercially interesting, in particular the electroluminescent (EL) lamp which is making an impact as a simple indicating device. A smooth transition is in progress from a first stage in which a reasonably efficient, convenient, reliable and cheap solid state visible light source is being produced, to a second stage where modest display requirements will be fulfilled by combining an array of EL lamps with fully integrated memory and addressing circuitry. It should then be possible to decide whether to continue towards a solid state display which will match and even surpass the cathode ray tube. With such grand plans, it is not surprising that the symposium on electroluminescent solid state devices arranged by the Institute of Physics and the Physical Society and the Institute of Electrical Engineers attracted 250 delegates to London on March 4.

Discussing gallium arsenide phosphide alloys, Dr C. E. E. Stewart (Standard Telephone Laboratories, Harlow) showed that not only II–VI materials have native defects, while Dr G. Lidgard (Plessey, Towcester) showed how the scanning electron microscope can be used for optimizing the combination of good minority carrier injection with efficient luminescence in gallium phosphide.

The wisdom of the almost total commitment of world effort to the light emitting diode rather than the electroluminescent panel is questionable, as Mr A. Vecht (Woolwich Polytechnic) showed when he summarized recent advances by his group working on zinc sulphide d.c. EL panels. Greater light output at 100 V d.c., a green alternative to the usual orange-yellow and no loss in brightness at constant input power during 500 hours of testing, emphasized the seriousness of the challenge. But it is becoming increasingly important to understand these devices sufficiently to decide whether the present poor half-life at constant voltage is curable, or whether it represents a fundamental limitation. Dr R. L. Rouse (GEC, Wembley) showed that such an understanding has not yet been reached when discussing the voltage dependence of ZnS d.c. EL panels.

The gallium arsenide infrared lamp coated with an up-converting phosphor is an interesting recent development. Dr W. A. Shand (Signals Research and Development Establishment, Christchurch) talked about the optimization of these phosphors. But the highlight of the day was a review of possible new tetrahedrally bonded materials for electroluminescence by Dr C. Hilsum (Royal Radar Establishment, Malvern). He thought that gallium nitride showed the greatest promise.

Practical problems of optimization and addressing were considered by Dr C. Gooch (Services Electronics Research Laboratory, Baldock), who felt that the immediate future depended on the commercial success with gallium phosphide and gallium arsenide phosphide lamps. The problem of integration of EL devices with silicon circuitry has been approached rather unusually by Dr J. Morant (University of Durham). He has found a phosphor (willemite) which is epitaxially compatible with silicon and is now hoping to make it efficiently electroluminescent.

POLLUTION

Teach-in at Edinburgh

from a Correspondent

On March 6, Edinburgh University was the venue for a teach-in at which scientists, economists, moral philosophers, politicians and representatives of industry discussed pollution with students and the public. This probably indicates a significant change in attitudes towards pollution since ten years ago, say, when reports of the effects of certain types of pollution were just reaching the public. The mood of the meeting was therefore one of "what are we going to do about it, when and how ?" It was good to see polluters and polluted facing up to one another on the same panel, so that the audience, consisting of some eight hundred people, was able to hear both sides of the problem.

Professor Alan Williams (University of York) pointed out that economics concerns things people value, and that a general achievement of a sense of values is difficult. For example, the cost of saving a few lives which might otherwise be lost due to a polluted water supply could be diverted to building a hospital to save many lives. It is dangerous, too, to take decisions on existing costs; in the end, what value will posterity place on action taken now ? Certainly, Canon Hugh Montefiore (University Church, Cambridge) felt that it was our moral duty to leave the Earth as we found it.

Some members of parliament were a little naive in their approach and alarmingly unaware of the inefficiency of some of the existing pollution legislation. Mr David Steele (MP for Roxburgh, Selkirk and Peebles), however, pointed out that it had taken general disasters to bring in certain legislation on pollution, and we must not wait for another disaster before doing anything further. Dr John Dunwoody (Parliamentary Under-Secretary, Ministry of Health and Social Security) agreed with this point, and felt that it was no use waiting for agreements on international control before action was taken. We must impose national controls, he said. The present position concerning the restriction of DDT indicates that this idea is shared by other nations.

One thing is certain, as Mr Roland Glover (Scottish Marine Biological Association), representing the Natural Environment Research Council, stressed. "It is no longer sensible to try to study ecology without considering man and society as significant components of the natural system. It will be necessary to improve and develop the environmental sciences as a whole so that our understanding of nature will be sufficient for us to diagnose and predict all the problems, of which pollution is but one, that are created by the changing pattern of society. The detection and measurement of the effects of pollution in the field will always be difficult, and often impossible, without a thorough understanding of the baselines of natural variation."

GIFTS FOR ACTIVE MINDS—

both indoors and outdoors at prices from 10/6 to £35. As only three are subject to a few shillings purchase tax they offer good value for money.

Write for a copy of this interesting brochure to-day.

W. A. QUINN LTD.

12 FULWOOD PLACE, HIGH HOLBORN, LONDON, W.C.1.
Telephone: 01-405 5268

"I can say...
'laboratory reagents for fluorescent antibody techniques, complement fixation tests, identification of bacteria and viruses, haematology, pregnancy diagnosis, buffering, radio-immunoassay, quality control sera, microtitrations and veterinary diagnosis'
in 12·5 seconds!
Beat that if you can!"

"Wellcome"

Quick, too, is the delivery of all these laboratory diagnostics from Wellcome Reagents Limited. They are subjected to rigorous quality control, their performance is consistent and they are backed by Wellcome Research Laboratories' own original immunological work.

Wellcome Reagents Limited
Wellcome Research Laboratories Beckenham Kent BR3 3BS

wright ACRYLIC chromatography columns

versatile inexpensive laboratory columns for chromatographic and gel filtration procedures employing aqueous solvents

Simple to use—unique patented design in acrylic and nylon with sintered plastics bed support.
Minimal dead space with low-volume connections. Diameters selected to produce cross-sectional area of 2, 4, 8, & 16 sq. cms.
Fixed or adjustable columns with or without jackets.
Standard lengths of 30, 60 and 90 cms.
Columns easily lengthened by joining.
Prompt delivery of standard columns from stock.
Preparative columns with bed volumes up to 50 litres are available to special order

Prices from **£5**

Phone or write for detailed catalogue to Dept. CC1/N

LOCARTE FLUORIMETER

Excitation wavelengths commencing at 240mμ

Now incorporating these novel features:

- **Output socket for chart recorder.**
- **Flow-through cuvettes.**
- **Automated fluorimetry with special converter unit for direct connection to most automatic analysing equipment.**
- **Stability ensured with fully regulated special Mercury Arc and Zinc lamp. Zinc lamp specially developed for plasma cortisol estimations.**

In laboratories throughout the world the Locarte Fluorimeter is saving time while providing unparalleled results. Important work demands precision. An extensive range of filters is available.

With an instrument so sensitive that monochromatic filter can be used on both primary and secondary sides many laboratories have extended their sphere of work. With an instrument so fast in operation your costs are reduced.

RAPID measurement of fluorescence (solution or filter paper).

SENSITIVITY: Minimum cuvette 'blank' allows full use of 13 stage photomultiplier and allows estimations well below 0·001 μg./ml. Quinine Sulphate; 0·001 μg./ml. Serotonin (measuring the fluorescence in the Ultra Violet at 335 mμ) and 0·1 μg. of Cortisol on filter paper.

REPRODUCIBILITY SPEED AND ACCURACY in all your fluorimetric estimations.

Locarte Precision equipment includes: Fraction Collectors, H.V. Electrophoresis, U.V. Handlamps, Recording Densitometers, Desalters, Column Scanners, Pipette Washers, Amino Acid Analysers.

Is the most profit to be had from research inspired by curiosity or by foresight of practical applications? A recent suggestion that the answer could be found by evaluating curiosity-oriented projects has proved hard to follow up.

A WAY to approach the problem of quantifying the economic benefits from curiosity-oriented research has recently been suggested by Byatt and Cohen[1]. It consists essentially of identifying key discoveries which have had profitable applications and then estimating the economic effects of notional marginal delays in the timing of these discoveries; that is, of attempting to assess how much less wealth, suitably discounted to a common year, would have arisen if, because of a smaller scale of effort in particular areas of research, certain discoveries had been made later than they actually were.

We report in this article some studies which formed part of a project* to assess the feasibility of this approach by trying to apply it to some recent examples of technological innovation. The examples were chosen after due consultation with the Working Group on the Economic Benefits of Scientific Research which has been established by the Council for Scientific Policy. The principal areas selected were the Chorleywood bread process, the float glass process and cryogenics. Some other areas of innovation were also considered more briefly.

The term "curiosity-oriented" used by Byatt and Cohen is clearer than "pure" or "basic", indicating research justified by curiosity about topics for which no application is apparent. According to Byatt and Cohen (benefit (*f*) of their article, paragraph 2), ideas discovered during curiosity-oriented research, which "tend to arise unpredictably", are sometimes applied later in industry. This is contrasted with "mission-oriented" research, defined by Byatt and Cohen (benefit (*c*)) as "research in fields whose application is evident".

Thus work cannot properly be described as curiosity-oriented if it can be shown that some application was envisaged; though naturally this does not imply that scientists necessarily lose interest just because there is a practical goal in view. The term "basic" is commonly used in a wider sense to include fundamental investigations of topics with a quite obvious application.

These distinctions are not just semantic subtleties. They are relevant to the possible policy problem of the extent to which basic research should be funded regardless of whether social or economic benefits seem relatively likely. The alternative is to try to identify topics which have obvious social and economic value and selectively support work in them, even though this work may be quite basic.

Chorleywood Bread Process

The principal feature of this process[2] is the replacement of a lengthy period of dough "development" involving fermentation by a combination of a controlled amount of intense mechanical work and the use of certain chemicals known as "improvers".

The effect of mechanical work was described by mission-oriented researchers[3] in the United States in 1926, thirty-five years before the Chorleywood process was announced by the British Baking Industries Research Association (BBIRA). No commercial application resulted until J. C. Baker in the United States was able to combine the effects of mechanical work with the use of improvers. Baker carried out careful systematic studies of a mission-oriented nature and no large input of curiosity-oriented research was involved[4].

Baker's "Do-Maker" process was not suitable for the needs of the British bakers or housewives, but the Chorleywood process is now used by more than two-thirds of the British baking industry. The Chorleywood process uses ascorbic acid (vitamin C) as a fast acting improver in addition to conventional improvers which were discovered in the 1920s by accident and by empirical research. The commercial availability of ascorbic acid depends on research in organic chemistry carried out in the 1930s but, had ascorbic acid not been available, other fast acting improvers could have been used[5].

The following quotations from Byatt and Cohen[1] indicate the main points of their argument.

2.14. "The economic value of the research derives from the total economic surplus—i.e., the total economic benefit derived from the final product or process, less the costs of applied research, development, investment and manufacturing. This surplus is a wider concept than the profit of an individual firm. It includes the profits of firms, and indeed the money, costs and receipts of manufacturing firms may, in a number of cases, be good measures of the economic benefit to society as a whole."

2.26. "The slowing down of the exploitation of new products and processes would usually result in an economic loss and an acceleration of the exploitation will usually result in economic gain. The extent of the change in the net economic benefit to society, when appropriately discounted, can be compared with that change in expenditure on research which results in this change. Only if the increase in net economic benefit from all the industries associated with the scientific discovery, when discounted, is equal to or exceeds the increased expenditures on research, will the extra expenditure have been worthwhile".

---

* The studies reported here were part of a larger project carried out in collaboration with the R and D Research Unit of the Manchester Business School where, under the direction of A. W. Pearson, work was carried out on the estimation of the economic benefits from the Chorleywood and float glass processes. J. R. G. worked at the unit. Work on the economic benefits from cryogenics was carried out by J. S. Metcalfe, of the Department of Economics, University of Manchester.

The technical knowledge forming the background to the research which produced the Chorleywood process was available in the 1930s, but could not have been used in Britain before the 1950s when chemical additives in flour and bread were allowed after studies by BBIRA.

While the allocation of greater resources to BBIRA might conceivably have brought about the development of the Chorleywood process slightly earlier, there is nothing to suggest that greater curiosity-oriented research effort would have had any accelerating effect.

Float Glass and Cryogenics

The float glass[6] process seems to be a typical "technological discovery" in that it cannot be described in terms of the application of a specific discovery made by academic or other curiosity-oriented scientists. The concept of using molten tin for the manufacture of flat glass was patented in America in 1902[7]; Pilkington had to spend seven years and £4 million on development work, however, before announcing the new process in 1959.

After the process had been developed empirically to the stage of producing satisfactory glass, scientists became involved to increase the understanding of the process and to solve technological problems; for example, the cause of a surface bloom was traced to a layer of tin dissolved in the glass. Such work made use of certain fundamental concepts and analytical techniques which may have derived from curiosity-oriented research; but it does not seem possible to apply the concept of marginal delay to these connexions between science and technology, which occurred after the initial development of the process.

We chose cryogenics to complement bread and glass manufacture, because it seemed *a priori* more likely to show dependence on curiosity-oriented research. We concentrated on the cryogenic gas-separation industry because it is too early to assess the economic impact of work at temperatures below about 20 K.

The history of low temperature research yielded one case that seemed at first to lend itself to Byatt–Cohen analysis. The Joule–Thomson effect[8], discovered in 1852, was in 1895 made the basis of a gas liquefaction process by Linde[9] in Germany and independently by Hampson in England[10–12]. It is at least plausible to argue, however, that a delay in the discovery might have accelerated rather than delayed its application. The Joule–Thomson effect was assimilated into science as a small scale effect and it required considerable insight on the part of Hampson and Linde to see it, as it were, "out of context" as part of a powerful industrial process. Had it been discovered after the failure of the Pictet[13] and Cailletet[14] approaches to liquefy oxygen on any but the very small scale, its potentialities as the basis of an industrial process might have been realized somewhat earlier.

Much of the explanation for the timing of the development of the industrial process seems to lie in market rather than technical factors: the realization of a large potential market for oxygen, to meet which only a relatively costly chemical process was available (ref. 15 and personal communications from personnel of the British Oxygen Co, formerly Brins Oxygen Co).

Other Innovations

Of several other major innovations considered more briefly in the course of this project, it seems that only nuclear power and silicones can legitimately be considered to be based on specific discoveries of curiosity-oriented research. In those two cases, the important influence of war-time development work makes it difficult to apply the concept of notional marginal delay; the timing of the innovations may have been determined more by the Second World War than by the timing of the curiosity-oriented discoveries. The massive effort put into the development of an atomic bomb is well known. Silicones could be said to depend on specific curiosity-oriented discoveries made by Kipping in 1904 and 1908. Silicones, however, were first produced commercially in 1943 by Dow–Corning to satisfy military needs and post-war production was based not on one of Kipping's reactions but on a synthesis developed by Rochow working for General Electric[16].

In several other cases, however, curiosity-oriented research may have been involved in the sense that knowledge and techniques were passed on through the educational process and made available for the solution of industrial problems via the supply of scientifically trained manpower. An example of such a problem is given in connexion with float glass.

In a further search for innovations which could be directly linked to curiosity-oriented research, issues of the *New Scientist* for the period January to June 1968 were surveyed, concentrating particularly on the Science in Industry feature. Of a sample of seventy-four British innovations thus obtained, fifteen (20 per cent) were considered possibly susceptible to Byatt–Cohen analysis, but in fourteen of these the chief reason for categorizing them thus was lack of precise knowledge.

Byatt–Cohen Hard to Find

From the studies we have summarized, we conclude that Byatt–Cohen type innovations are quite difficult to find, let alone investigate. Interactions between science and technology are usually too complex for the method of notional marginal delay. Only rarely is it possible to pinpoint specific curiosity-oriented discoveries from which wealth-producing applications are derived. Even when this can be done, other factors affecting the timing of innovations, such as market factors or war-time pressures, obscure the effects of possible delays in discoveries.

It should be emphasized that we do not conclude that curiosity-oriented research is useless in economic terms. On the contrary, in view of the importance of the problem, we feel that further work should be directed to exploring various other avenues through which curiosity-oriented research may lead to economic benefits.

We thank Drs Byatt and Cohen for making available pre-publication copies of their article, and them and other members of the secretariat of the Council for Scientific Policy for helpful discussions. J. R. G., D. S. W. and J. L. were supported by the DES.

Imperfections of Elasticity and Continental Drift

by
HAROLD JEFFREYS
St John's College,
Cambridge

Imperfection of elasticity in the Earth follows a law that forbids convection and continental drift.

CONTINENTAL drift is the subject of so much discussion that I think some remarks about the history of the hypothesis are worth making. Wegener attempted an explanation involving a small force acting on a floating continent and tending to push it towards the equator. As a meteorologist he thought that the Earth's rotation would convert this into a westerly drift. It did not occur to him that the viscosity of the Earth was so high that its effect would overwhelm that of rotation, and the effect, if any, would be to spread the continents symmetrically about the equator. He also assumed that the viscosity extended right up to the ocean floor; but if this were so the ocean floor would be flat. In fact, the inequalities are of the same order as those of the land surface.

Wegener claimed that vertical movement was impossible, supposing a form of isostasy, according to which excess height is compensated exactly by extra thickness of light matter, leaving the continents floating like icebergs. Even in his time it was known that gravity departed from the values calculated on this hypothesis by about ten times the errors of observation; much larger departures have been found since. Furthermore, geologists were familiar with deep sediments. They supposed that the sea floor could be depressed as the sediments accumulated, so as to leave little disturbance of gravity. Two geologists, Morley Davies and E. M. Anderson, however, showed that the depression produced in this way would not be at all adequate. At most about 2 km of sediments could be deposited in water originally 1 km deep. To get 6 km of sediments we should need 3 km of water, possibly a great deal more, on the continental shelf. Such thicknesses are known.

Little is heard now about Wegener's mechanism. But Holmes, followed by Meinesz, used convection currents. These had the advantage that not much was known about their theory. But in the past few years a great deal of relevant information has appeared. The fundamental matter is the behaviour of solids under continued shear stress. If this is great enough they break at near 90° or 45° to the greatest principal stress, sometimes with and sometimes without deformation nearby. This happens in rocks when lengths are changed by something like 1 part in 1,000 and is familiar enough to geologists. But there is evidence of some sort of imperfection of elasticity at extensions of the order of 10^{-6} or less. Early workers, on various materials, found continuous creep at low stresses, behaving like $\log t$ or $t^{1/3}$. These met a difficulty, for the rate of increase of strain would be infinite at zero time. But C. Lomnitz noted two things. One was that at extensions of the order of 10^{-4}–10^{-5} the stress–strain relation was linear; if so, extrapolation to smaller stresses would probably be justified. The other was that if a constant shear stress P is applied at $t=0$, and the shear is

$$\varepsilon = \frac{P}{\mu}\left[1+q\log\left(1+at\right)\right]$$

where μ is the rigidity and q and a are constants, the creep when at is large approximates to $q \log (at)$ times the initial yield. But at small at, $d\varepsilon/dt$ has a finite limit. This is one of the obvious things that take a very long time for somebody to notice. For time 1 s, estimates of at from 10^3 to 10^5 exist, but in any case 1 can be neglected in comparison with at for any motions of geophysical interest.

The power law can be adapted similarly

$$\varepsilon = \frac{P}{\mu}\left[1+\frac{q}{\alpha}\left\{\left(1+at\right)^{\alpha}-1\right\}\right]$$

If $\alpha=1$ the creep becomes $(P/\mu)qat$, so that it varies linearly with time as for ordinary viscosity (elasticoviscosity). For a forced vibration of period T the lag is as T^{α}, tending to a constant as $\alpha \rightarrow 0$. The amplitude of a wave travelling a wavelength contains an exponent as $(\text{period})^{\alpha}$; of one travelling a given distance as $(\text{period})^{-1+\alpha}$, with a factor depending on distance alone. In addition there is a small increase in the time of travel except for $\alpha=1$.

Damping of Waves

There has been a great deal of recent work on the damping of surface waves and free vibrations. Nearly all of it assumes the logarithmic form, giving the damping in a period independent of period. In addition the free nutation of the Earth's axis (otherwise the 14-monthly variation of latitude) shows damping with a time of relaxation of the order of 30 years. Stuart Crampin and I have shown that this, with $\alpha=0$, would ruin seismology[1]. If a sharp transverse wave is generated, its beginning at distance 80° would be spread out over about 70 s, and it would be unreadable. On the approximately correct assumption that it reaches half its ultimate amplitude in 2 s, α has to be about 0·2. The data used on the logarithmic law cover periods from about 10 to 2,000 s, and $(200)^{0 \cdot 2}$ is about 3, so that failure to detect $\alpha>0$ from seismological data alone is not hard to understand. The range of period covered, when the free nutation is taken into account, is by a factor of 10^7.

Convection

The equations for the initiation of convection in a fluid are well known. Viscosity has a controlling effect. When the viscosity term is replaced by any law with $\alpha<1$ it is found that the equations cannot be made to balance. The essential point is that to maintain steady upward and downward currents there must be steady horizontal flow between them, which must be maintained by differences of pressure. But if the differences of pressure are constant the rates of flow according to any law with $\alpha<1$ will die down, and there is a contradiction. Convection demands the elasticoviscous law, which is contradicted by all the available evidence. Similarly, to maintain continental drift, in any way, at a constant rate would require a steadily increasing force.

It has been suggested that the law might break down and approximate to elasticoviscosity when still longer intervals of time are considered. The best way to test a law is to apply it as far as possible beyond the original data and see what happens. One test is on the gravity anomalies disclosed by the work on artificial satellites.

With any law of imperfection of elasticity at small stresses these should be subsiding, and the rate of subsidence would be much more rapid for the widest-spread anomalies. If an anomaly of 100 km in horizontal extent has had time to be reduced to half its original amount, an anomaly of 3,000 km would be reduced to 10^{-9} of its original amount. But the greatest discoveries resulting from work with artificial satellites are the uncompensated second and third harmonics in the gravitational field. This difficulty disappears with the modified Lomnitz law. In 10^8 years a harmonic of degree 2 would be about halved, and one of wavelength 10^8 km perhaps reduced by 10 per cent. The law does not explain the approximate compensation of mountain systems, but the stresses are of the order needed for fracture anyhow.

Using the Moon for Further Checks

The principal evidence for any imperfection of elasticity at very small stresses is from the fact that the Moon keeps a constant face to the Earth. With the same values of q and α as for the Earth, Crampin and I find that this could easily be achieved in 10^7 years. In addition the Moon is dynamically triaxial and the chief effect of this is the inclination of its axis to the normal to the ecliptic. With the same values the difference of the moments of inertia would have decreased by about 10 per cent in 3×10^9 years. But if we assume elasticoviscosity to fit the damping of the free nutation of the Earth the difference would have been halved in the past 200 years, the interval of reasonably accurate observation.

Because of triaxiality the Moon theoretically has three free oscillations with periods of about 1, 40 and 800 months in the directions of its axes. These have not been detected. With the same constants they would have times of relaxation of the order of 10^6 years, so there is no difficulty in understanding why they have not been found.

The criterion that the law should be tested by application far beyond the original data is therefore satisfied. It is worth pointing out, however, that the data concern a free oscillation of the whole of the Earth's shell and a wave that has gone nearly to its base, so that the results must be interpreted as average properties for the shell. There is a good deal of evidence from surface waves that qa^a in the top 100 km or so is of the order of ten times this value. The data are enough to show that α is nowhere near 1. This would imply that so far as this type of imperfection of elasticity is concerned the elasticity becomes more nearly perfect with depth, contrary to what has usually been expected.

---

Some Needs of Geophysics

by Harold Jeffreys

MUCH further work is needed before we can understand several important facts, some of which have been known for fifty years or more.

First, we need a general survey of gravity, such that every point of the surface is within 5° of a place where gravity has been measured. Artificial satellites have given good determinations of the gravitational potential at least to all harmonics of degree 4, and far better than gravity surveys alone can give. But gravity can still give valuable information for the contributions from the higher harmonics to the distribution of potential over limited regions, notably for the correction of estimates of the mean radius of the Earth for deflexion of the vertical. The function that arises in Stokes's theorem keeps the same sign over long intervals of distance, so that unsurveyed regions are liable to make considerable contributions over regions where gravity is well observed. But if Stokes's function is modified by omission of harmonics up to degree 4 it keeps the same sign over much shorter distances and the contributions from the higher harmonics would be much better determined.

Second, on any theory of mountain formation it is hard to understand why so many of the major mountain chains are in western China or near its borders. A factor of 2 in the apparent crumpling on different great circles would be easy to understand, but the ratio is more like 5 or possibly 10. It might be due to specially great thickness of the lighter upper layers there; this could be tested by a gravity survey.

Third, since the present standard times of travel of seismic waves were produced, the number of observations of P (longitudinal waves) has greatly increased, chiefly through the use of new stations with instruments of high magnification and short period (1 s or so). This has been mainly for the rapid and accurate determination of epicentres. But the accuracy for S (transverse waves) has diminished. The reason is that the prevailing periods in S are of 4 s to 7 s and the new instruments are insensitive to them. In many respects S is more interesting than P, and the new stations should be equipped with instruments capable of recording these periods. This applies specially to the phase SKS, which provides the most direct evidence on velocities at small depths in the core.

Provisionally I think that the cost of this work would be between 1 and 10 per cent of that of sending up one artificial satellite and 0·01 per cent of that of a landing on the Moon.

Fourth, with any law of imperfection of elasticity, if vertical movements are due to differences of surface load, they should be fairly directly related to gravity anomalies. So far as I know no comparison has ever been made except for Fenno-Scandia, and there is no evidence that the conclusions drawn from it are general; there is a good deal of evidence against it. Geodesists have a habit of speaking of any vertical movement as isostatic, which begs the question of spontaneous internal change. We need a detailed comparison.

Fifth, we know a great deal about elasticity when the stresses are well below the strength, and it is not difficult to adapt the results to any linear law of imperfect elasticity. But near the elastic limit the stress–strain relations are far from linear, even before fracture. The great distortions found in geology are understood only to the extent that something like them can be obtained in the laboratory and can be seen in the convolutions of boulder clay, where we have more direct knowledge of the forces acting. A quantitative theory of plastic instability is needed. A simple case is that of a plastic rod under tension ('Plasticine' will do). If it becomes slightly thinner in one place, the tensile force per unit area is increased there, and flow becomes faster, until the specimen is thin enough there to break.

Positive Control of Transcription by a Bacteriophage Sigma Factor

by
ANDREW A. TRAVERS
The Biological Laboratories,
Harvard University

A sigma specificity factor induced by infection with bacteriophage T4 directs the *in vitro* synthesis of RNA species corresponding to those switched on *in vivo* about 2 min after infection.

DURING the course of bacteriophage T4 development, different classes of viral RNA are synthesized in a defined temporal sequence[1-5]. The earliest studies[1-3] distinguished two principal classes of T4-specific RNA: early and late, transcribed predominantly before and during DNA replication, respectively. More recent work[4,5] has shown, however, that early RNA can itself be separated into at least two distinct classes. The first of these, class I or pre-early, appears immediately after phage infection while the second, class II or early, is switched on about 2 min after infection at 30° C. The synthesis of all classes of phage RNA, except pre-early RNA, is dependent on phage specific protein synthesis[4,5], indicating that the switching on of RNA species characteristic of later stages of the infection cycle requires at least one component of the transcription machinery to be phage-coded.

Recently a molecular mechanism for such positive control of transcription was suggested by the elucidation of the role of the RNA polymerase σ factor[6,7]. This factor directs the accurate initiation of selective transcription by the core RNA polymerase, the enzymatic machinery for synthesizing RNA (refs. 8, 9). For example, with T4 DNA as template, σ factor directs the initiation of pre-early RNA species *in vitro*[8,10,11]. Because the host core polymerase is conserved, at least in part, throughout the infection cycle (ref. 12 and personal communication from C. G. Goff), it seemed probable that phage coded factors analogous to σ might direct the synthesis of the later species of RNA. Such a factor was recently identified in T4 infected cells[13]. This factor, termed σ^{T4}, stimulates transcription only on T-even phage DNA and even depresses the non-specific synthesis by the core polymerase on other DNA templates. An additional alteration of the host transcription machinery after infection with phage T4 is the modification of the α subunit of the core polymerase[14-16]. We show here that σ^{T4} directs the synthesis of early RNA and further that the specificity of initiation is determined primarily by the type of factor and is not affected by the modification of the core polymerase.

Isolation of σ^{T4}

Because the original procedure described for the isolation of a T4-coded sigma factor is unsuitable for processing large quantities of cells, we have developed an alternative method. The cells are grown, infected and harvested as previously described and are then lysed by grinding briefly with alumina instead of by a lysozyme–freeze/thaw treatment. After removal of alumina and cell debris by centrifugation, the crude cell extract is fractionated into a supernatant fraction and a ribosomal pellet. This pellet is then washed with a buffer of high ionic strength to elute absorbed protein. With both methods of lysis the σ^{T4} activity is normally found preferentially in the ribosomal wash, although in about 30 per cent of all preparations the factor was uniformly distributed between the ribosomal pellet and the supernatant fraction. The σ^{T4} factor can be separated from the core polymerase by fractionation of the ribosomal wash by precipitation with ammonium sulphate (Table 1). Most of the RNA polymerase activity is recovered in the fraction precipitating between 25 and 40 per cent saturation with ammonium sulphate. This polymerase preparation transcribes calf thymus DNA well and exhibits a low but significant activity on T4 DNA. It thus probably contains mainly core polymerase with a small amount of σ^{T4}. Addition of the fraction precipitating between 40 and 55 per cent saturation to the polymerase fraction greatly enhances the activity on T4 DNA, however, while RNA synthesis on calf thymus DNA is depressed. Because the 40–55 per cent cut has negligible RNA polymerase activity it must contain σ^{T4}, and was used as a source of this factor in these experiments.

Table 1. TEMPLATE SPECIFICITY OF TRANSCRIPTION DURING PURIFICATION OF σ^{T4}

Fraction DNA template:	^{14}C-AMP incorporated (pmoles/0·1 ml.) T4 (37 μg/ml.)	Calf thymus (37 μg/ml.)	Ratio of activity, T4 DNA/calf thymus DNA
Ribosomal wash (42 μg)	132	36	3·7
Ammonium sulphate precipitates:			
25–40 per cent (16 μg)	64	352	0·18
40–55 per cent (13 μg)	23	15	—
25–40 per cent cut (16 μg) + 40–55 per cent cut (13 μg)	248	69	3·6

To separate core polymerase and σ^{T4} by fractional precipitation with ammonium sulphate, the ribosomal wash from T4 infected cells was prepared as previously described[13] except that the cells were lysed by grinding them for 2 min with twice the cell wet weight of alumina. The paste of alumina and lysed cells was resuspended in 1 volume of standard buffer (0·01 M Tris-HCl, *p*H 7·9, at 25° C, 0·005 M $MgCl_2$, 0·005 M 2-mercaptoethanol, 0·0001 M EDTA, 0·05 M KCl) per wet weight of cells. 10 ml. of ribosomal wash was brought to 25 per cent saturation with ammonium sulphate by the addition of a saturated solution, *p*H 8, and allowed to stand 15 min at 4° C. The solution was centrifuged and the supernatant was then brought to 40 per cent saturation with ammonium sulphate, allowed to equilibrate for 15 min, and finally centrifuged. The pellet was redissolved in 1·5 ml. standard buffer while the second supernatant was brought to 55 per cent saturation with ammonium sulphate. Once again the precipitate was collected by centrifugation and redissolved in 1·5 ml. standard buffer. The redissolved pellets were assayed for RNA polymerase activity on calf thymus and T4 DNA as previously described[13]. The background incorporation in the absence of added DNA has been subtracted from all data; in no case did this background exceed 9 per cent of the maximum observed incorporation. The amounts of protein added to the assay mixture are indicated in parentheses.

Asymmetric Transcription by Reconstituted System

Previously we have shown that the crude mixture of T4 factor and RNA polymerase in the ribosomal wash transcribes mature T4 DNA in a highly asymmetric manner, only the l-strand of the T4 DNA being copied[13]. Bautz *et al.*[8] have demonstrated, however, that the core polymerase, whether modified or not, transcribes T4 DNA as though RNA chains were initiated almost at random along the entire DNA molecule. By measuring the asymmetry of RNA synthesis in such reconstituted systems, we have asked whether the addition of σ^{T4} to core polymerase restores the specificity of transcription of the T4 genome. The results (Table 2) show that when σ^{T4} directs RNA synthesis either by host core polymerase or by T4-modified core polymerase more than 90 per cent of the RNA product hybridizes to the l-strand of T4 DNA. Similarly, RNA synthesized by either host or modified core polymerase under the direction of the host σ factor also hybridizes almost exclusively to the l-strand.

σ^{T4} directs the Synthesis of Early RNA

During normal phage development, RNA complementary to the l-strand of T4 DNA is synthesized at all times

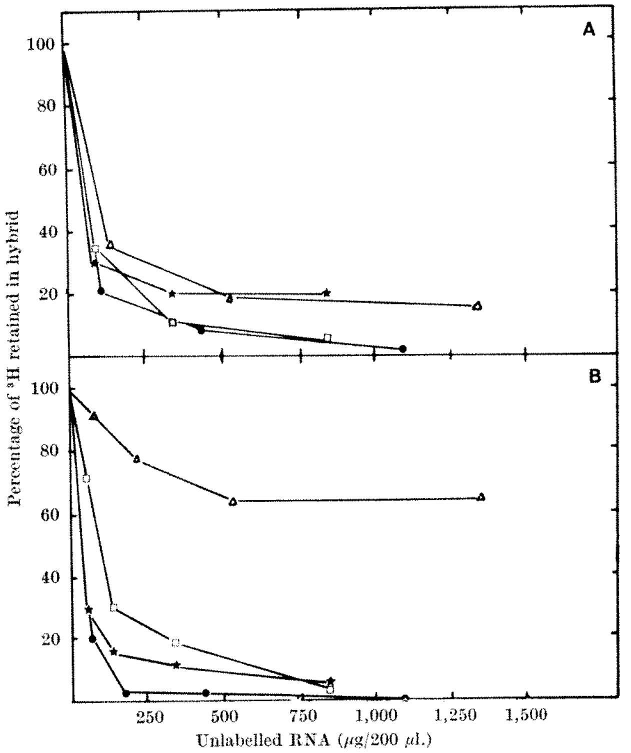

Fig. 1. RNA–DNA hybridization competition experiments comparing σ^{T4} directed T4 RNA and *E. coli* σ directed RNA with *in vivo* T4 RNA. The *in vivo* RNA was extracted from T4 infected cells at 3 min, 8 min and 16 min after infection by the method of Bolle *et al.*[25]. T4 CM RNA was extracted 3 min after infection from cells to which chloramphenicol (100 µg) had been added 1 min before infection. T4 ^{3}H-RNA was prepared as described in the legend to Table 2. Hybridization of *in vitro* T4 ^{3}H-RNA to 10 µg/ml. T4 l-strand in the presence of increasing amounts of RNA was performed as described in the legend to Table 2. *A*, Competition of RNA synthesized *in vitro* by complex of *E. coli* σ and *E. coli* core polymerase. Input, 2,680 c.p.m.; hybridization efficiency, 24 per cent. *B*, Competition of RNA synthesized *in vitro* by σ^{T4} and T4 core polymerase. Input, 2,180 c.p.m.; hybridization efficiency, 31 per cent. Competitor RNA species: CM RNA (△); 3 min RNA (□); 8 min RNA (●); 16 min RNA (★).

after infection whereas transcription from the r-strand does not become significant until 10 min after infection[17]. To determine whether σ^{T4} directed the synthesis *in vitro* of RNA species containing nucleotide sequences homologous to those in *in vivo* T4 RNA species, we competed labelled σ^{T4} directed RNA and also host σ directed RNA with unlabelled *in vivo* T4 RNA isolated at 3 min, 8 min and 16 min after infection. In addition, competition was carried out with T4 RNA isolated from cells treated with chloramphenicol (CM) before infection. CM RNA is identical to pre-early RNA, and presumably only the host transcription machinery is required for its synthesis *in vivo*. The results (Fig. 1) show that whereas CM RNA is a relatively poor competitor of σ^{T4} directed RNA, only competing for about 40 per cent of the radioactive label, the RNAs at 3 min, 8 min and 16 min are good competitors, virtually 100 per cent competition being observed. Because the efficiency of hybridization in conditions of DNA excess is high (about 80–90 per cent) this complete competition demonstrates that all the nucleotide sequences in σ^{T4} directed RNA are homologous to *in vivo* messages. The corollary of this conclusion is that little or no antimessenger is synthesized in the presence of σ^{T4}. By marked contrast, when core polymerase transcribes T4 DNA in the absence of any σ factor, about 30 per cent of the resulting RNA is self complementary[8]. Unlike σ^{T4} directed RNA, host σ directed RNA was well competed by CM RNA. Similarly 3 min and 8 min RNA were good competitors but 16 min RNA had slightly diminished competing capacity. Maximum competition was achieved by 3 min RNA where more than 97 per cent of the labelled RNA could be diluted out.

Table 2. ASYMMETRY OF *in vitro* TRANSCRIPTION BY RECONSTITUTED CORE POLYMERASE–FACTOR COMPLEXES

Core polymerase	σ factor	Input c.p.m.	Hybridization r-strand (c.p.m.)	Hybridization l-strand (c.p.m.)	Hybridization (ratio r : l)
E. coli	*E. coli*	1,340	45	1,019	4·2 : 95·8
E. coli	T4	1,810	5	1,532	0·3 : 99·7
T4	*E. coli*	1,260	16	1,109	1·4 : 98·6
T4	T4	1,090	18	775	2·3 : 97·7

T4 SH-RNA was prepared as previously described[13], the labelled precursor being ^{3}H-ATP (specific activity 24 Ci/mmole). The reaction mixtures contained per ml., as appropriate, *Escherichia coli* core polymerase, 25 µg; *E. coli* σ, 50 µg; T4 core polymerase, 36 µg; σ^{T4} (as the 40–55 per cent ammonium sulphate fraction), 156 µg. The core polymerases were prepared by the method of Burgess[24]. Incubation of the reaction mixtures was for 4 min at 37° C. Aliquots of the ^{3}H-RNA were annealed in 0·03 M sodium citrate–0·3 M NaCl for 4 h at 66° C with 5 µg/ml. of either the l or r-strand of T4 DNA in a reaction volume of 200 µl. The DNA–RNA hybrids were measured as previously described[13]. Data have been corrected for radioactivity retained by the nitrocellulose filter in the absence of added DNA. These backgrounds were in the range of 10–20 c.p.m.

The difference in the ability of host σ directed RNA and σ^{T4} directed RNA to be competed by CM RNA confirms the previous observation[13] that the two σ factors direct the synthesis of qualitatively different sets of RNA. The good competition of host directed RNA by CM RNA strongly supports the demonstration by Bautz *et al.*[8] that σ directs the synthesis of pre-early RNA. Because most of the σ^{T4} directed RNA species are competed by 3 min RNA but not by CM RNA, we conclude that σ^{T4} must direct the synthesis of early RNA which is switched on between 1·75 min and 2·5 min after infection[4,5].

Modification of Core Polymerase does not affect Specificity

We have shown that the host core + host σ and T4-modified core + σ^{T4} complexes synthesize different classes of T4 RNA. The recognition unit for the correct initiation of transcription is probably the complex of core polymerase and factor, so we asked whether it was necessary to change both components in order to change the specificity of RNA synthesis. Accordingly we tested RNA synthesized *in vitro* by host core + σ^{T4} or T4 modified core + host σ reconstituted complexes by competing these RNA samples with *in vivo* T4 RNA. The results (Fig. 2) demonstrate

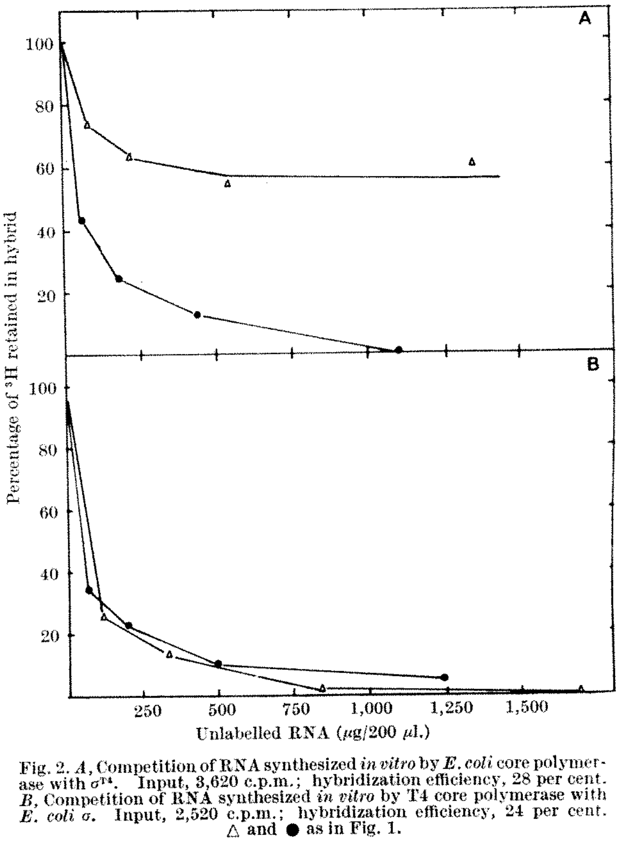

Fig. 2. *A*, Competition of RNA synthesized *in vitro* by *E. coli* core polymerase with σ^{T4}. Input, 3,620 c.p.m.; hybridization efficiency, 28 per cent. *B*, Competition of RNA synthesized *in vitro* by T4 core polymerase with *E. coli* σ. Input, 2,520 c.p.m.; hybridization efficiency, 24 per cent. △ and ● as in Fig. 1.

that σ^{T4} directs host core polymerase to synthesize early RNA and host σ directs T4 modified core polymerase to synthesize pre-early RNA. The amount of competition by the *in vivo* species is almost identical in this case to that observed during competition of RNA synthesized by homologous core–factor complexes. Thus it is clear that in this system the specificity of transcription is determined primarily by the type of factor and not by the modification of the core.

The Role of σ^{T4}

Two models have been proposed to explain why different classes of phage messenger RNA appear sequentially early in the infection cycle[4,5,10]. This effect could arise either from sequential non-synchronous initiation of different transcription units or from the propagation of transcription along synchronously initiated transcription units of appreciable length. The experiments reported here clearly strongly support the first hypothesis. σ^{T4} must act at the level of initiation, for in addition to stimulating RNA synthesis on T4 DNA it depresses random initiation by core polymerase on such templates as T7 and calf thymus DNA (ref. 13). Milanesi *et al.*[10] have shown, however, that the sequential appearance of pre-early and early RNA *in vivo* can be exactly paralleled *in vitro* using only the host complex of factor and core together with T4 DNA. This observation can be explained by the lack of natural RNA chain termination in this highly purified *in vitro* system, because in the presence of the RNA synthesis termination factor, ρ (ref. 18), host σ directs the synthesis of pre-early RNA but without it both pre-early and early RNA sequences are transcribed (Table 3). That in the absence of ρ, host σ initiated core polymerase does read through into early sequences is confirmed by the observation that host σ directed RNA synthesized for 10 min at 37° C is a good competitor of σ^{T4} directed RNA whereas host σ directed RNA synthesized for 5 min competes similarly to CM RNA (Fig. 3). All these results strongly suggest that pre-early and early RNA sequences occur on adjacent regions of the T4 chromosome and, further, that their arrangement must be such that the promoters for early RNA species are close to the termination signals for pre-early RNA sequences. Kasai and Bautz[19] have shown that promoters for pre-early species occur at widely separated points on the T4 genome and also that early genes are similarly scattered. Both host σ and σ^{T4} must therefore each direct the synthesis of several different T4 RNA species.

Table 3. EFFECT OF ϱ ON HOST σ DIRECTED RNA SYNTHESIS *in vitro*

In vitro RNA	Competition by *in vivo* RNA CM RNA	8 min RNA
E. coli σ and core polymerase + ϱ	89	94
E. coli σ and core polymerase alone	51	93

T4 ^{14}C-RNA was synthesized *in vitro* in the presence and absence of purified ϱ factor for 20 min at 37° C. The reaction mixtures contained per ml. as appropriate: *E. coli* complex of core polymerase and σ, 30 μg; ϱ factor, 20 μg; T4 DNA, 15 μg. Other conditions were as specified in the legend to Table 2 except that [KCl] = 0·1 M. The reactions were terminated by the addition of phenol and the ^{14}C-RNA was annealed to 10 μg/ml. T4 l-strand in the presence of increasing amounts of unlabelled *in vivo* T4 RNA. Hybridization was performed as described in the legend to Fig. 2. The figures for extent of competition by CM RNA (1,350 μg/200 μl.), and 8 min RNA (1,100 μg/200 μl.) are plateau values. The experiment was performed in collaboration with Dr J. Roberts.

Do host σ and σ^{T4} direct the synthesis of independent or overlapping sets of RNA species ? Because host σ directed RNA is not merely a subset of σ^{T4} directed RNA (ref. 13), the 40 per cent competition of σ^{T4} directed *in vitro* T4 RNA by *in vivo* CM RNA suggests that the sets are overlapping. Support for this idea is provided by the results of Hosoda and Levinthal[20], who have shown that whereas some of the T4 proteins that are synthesized immediately after phage infection are switched off after 8 min at 25° C, others continue to be synthesized until 20 min. These latter proteins behave similarly in this respect to another class of proteins which is switched on about 3 min after infection and which is probably coded by early RNA species. It is perhaps significant that when cells are infected with a T4 phage mutant in gene 55 (such a phage is unable to synthesize late RNA (ref. 21)) the RNA synthesized between 8 min and 11 min after infection is quantitatively similar in its ability to be competed by CM RNA (ref. 5) to σ^{T4} directed *in vitro* RNA. Thus the characteristics of *in vivo* transcription in this phage can be explained simply by assuming that σ^{T4} is responsible for directing all transcription after the host σ factor ceases to function.

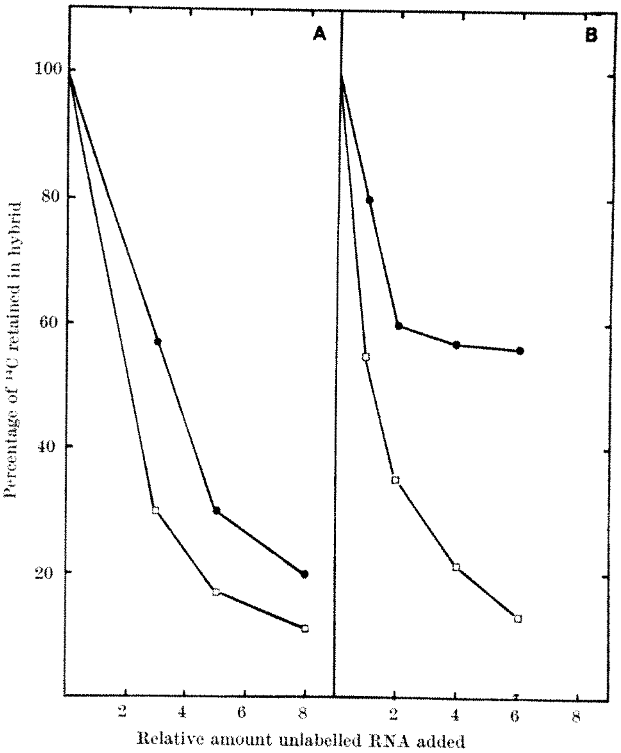

Fig. 3. Readthrough by *E. coli* σ initiated RNA polymerase into sequences transcribed by σ^{T4} initiated polymerase. ^{14}C-labelled precursor was ^{14}C-ATP (specific activity 35 Ci/mole) and unlabelled RNA samples were synthesized in parallel tubes as described in the legend to Table 2. In each case ^{14}C-RNA was annealed to 0·2 μg/ml. T4 l-strand in the presence of increasing amounts of unlabelled RNA. *A*, □, Competition of 10 min ^{14}C-labelled *E. coli* σ directed RNA by unlabelled 10 min *E. coli* σ directed RNA; input, 3,410 c.p.m.; hybridization efficiency, 33 per cent. ●, Competition of 5 min ^{14}C-labelled T4 σ directed RNA by unlabelled 10 min *E. coli* directed RNA; input, 2,880 c.p.m.; hybridization efficiency, 27 per cent. *B*, □, competition of 5 min ^{14}C-labelled *E. coli* σ directed RNA by unlabelled 5 min *E. coli* σ directed RNA; input, 3,200 c.p.m.; hybridization efficiency 31 per cent. ●, Competition of 5 min ^{14}C-labelled T4 σ directed RNA by unlabelled 5 min *E. coli* σ directed RNA; input, 2,880 c.p.m.; hybridization efficiency, 27 per cent. The times given are the length of synthesis at 37° C.

We can tentatively formulate a model for the events which take place immediately after infection by phage T4. On injection of the phage DNA into the bacterium the host core–factor complex rapidly binds to this DNA (ref. 22) and initiates the synthesis of pre-early RNA. Among the proteins coded by this RNA would be the σ^{T4} and possibly the enzyme responsible for the modification of the core polymerase. σ^{T4} then directs the synthesis of delayed early RNA together with certain immediate early RNA species. Meanwhile, the synthesis of those pre-early species not directed by the T4 factor would be switched off[19]. This switch-off would result from the functional replacement of the host factor by the T4 factor. The mechanism of such a replacement is obscure, but it is noteworthy that host σ factor activity is only detectable in T4 infected cells immediately after infection and is not found at late times[13–15]. One possibility is that the modification of the core polymerase reduces the affinity for the host factor, thereby allowing the T4 factor to bind preferentially to the core polymerase.

The only experimental finding which is not compatible with this model is the timing of the appearance of the σ^{T4} factor in infected cells. *In vivo*, early RNA is switched on about 2 min after infection at 30° C (refs. 4 and 5), while the T4 sigma factor cannot be detected until after 5 min from infection[13]. It remains possible, however, that the assay for the factor is not sufficiently sensitive to detect it earlier. Indeed, Schmidt, Mazaitis and Bautz (personal communication) have tentatively identified an early promoter in the rIIB region which is active *in vivo* about 2 min after infection and which is not read by the *E. coli* σ factor[8]. The obvious conclusion is that this early promoter site is recognized by a phage-specific factor.

The experiments reported here confirm the model of positive gene control[13,23] in which transcription can be regulated by altering the initiation specificity of RNA polymerase. This specificity is determined primarily by the σ factors and is altered during the development of phage T4 and also T7 (ref. 23) by the substitution of a phage-induced factor for the host factor.

I thank Mrs Christine Roberts for technical assistance and Professors J. D. Watson, W. Gilbert and K. Weber and Dr J. Roberts and C. Goff for discussions. This work was carried out during the tenure of a Damon Runyon Memorial fellowship and was supported in part by a grant from the US Public Health Service.

Involvement of a Phage T4 σ Factor and an Anti-terminator Protein in the Transcription of Early T4 Genes *in vivo*

by

The existence of an rIIB promoter site not recognized by the *Escherichia coli* σ factor is demonstrated. Early synthesis of lysozyme messengers seems to result from the lack of termination of pre-early transcription.

STUDIES on the regulation of transcription of the bacteriophage T4 genome have indicated that at least two distinct classes of genes are transcribed in succession before the onset of phage DNA replication[1,2]. The discovery of the RNA polymerase σ factor which is required for proper transcription of T4 DNA *in vitro*[3] suggested that the expression of the first class of genes (the pre-early genes) would be under the control of this host factor. When this was confirmed[4], it seemed very likely that the second class of genes (the early genes) would be under the control of another—a phage-specific—σ factor. The reported finding of a σ-like factor in phage-infected *E. coli* cells[5], having most of the expected properties of a hypothetical early T4 factor, has strongly supported this idea, especially because it was also observed that addition of chloramphenicol at or before the time of infection prevented transcription of the early genes[2,6,7]. Thus the discovery of transcription factors seemed to explain the regulatory mechanisms involved in prereplicative RNA synthesis in a most satisfactory way.

The fact that *E. coli* RNA polymerase *in vitro* mimics the *in vivo* situation—in that it transcribes sequentially first the pre-early and then the early genes[8]—suggests, however, that the two classes of genes are interspersed and that RNA polymerase reads past the boundaries between pre-early and early genes. The chloramphenicol data could then be interpreted as indicating the existence of transcriptional termination signals between pre-early and early genes which are recognized neither *in vitro*, because of the lack of a termination factor in highly purified RNA polymerase, nor *in vivo*, because of the phage-directed synthesis of an anti-terminator protein which inhibits the host's termination factor. Indeed, addition of a termination protein[9] to *E. coli* RNA polymerase results in the *in vitro* transcription of only pre-early T4 genes (personal communication from A. A. Travers). There are therefore two diverging lines of evidence leading to two different hypotheses explaining the transcription switch from pre-early to early genes, namely the T4 σ factor and T4 anti-terminator hypotheses.

Previous studies in this laboratory on the time-dependent transcription of genetically defined regions of the T4 genome demonstrated that of the three regions studied, *e*, rII and D_2, none seemed to be regulated identically with either of the other two[1]. Here we report further data on the transcription of these regions, and

---

* Present address: Department of Biochemistry, New York University School of Medicine.

present evidence that (1) transcription of the rIIB cistron is at least partially under the control of an early promoter site, and (2) the early transcription of the *e* gene is probably attributable to non-termination of transcription of a neighbouring pre-early gene. To explain these results, we have to conclude that both the recognition of a second set of promoter sites as well as the lack of termination are sharing in the controls which operate in prereplicative RNA synthesis.

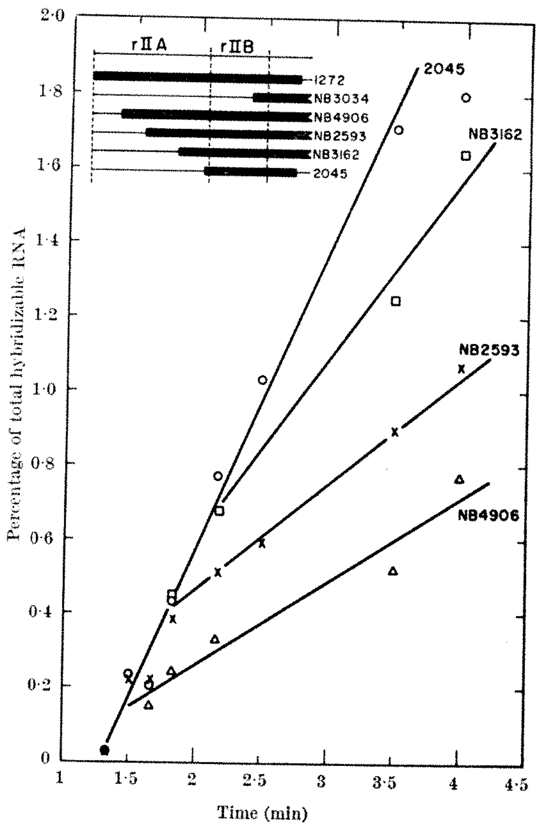

Fig. 1. Kinetics of transcription of the rIIA cistron. *E. coli* BA cells, grown with aeration in minimal salts (MS) plus glucose medium at 37° C to 5×10^8 cells/ml., were poured on to 0·2–0·5 volume of finely crushed frozen MS, centrifuged, resuspended in a small volume of cold MS, and kept at 0° C. After addition of tryptophan solution, the bacteria were each infected with 5–8 T4 wild-type phages, kept in the cold for 90 s to allow phage adsorption, and diluted 1 : 5 or 1 : 10 to 5×10^8 cells/ml. by simultaneously blowing aliquots of the infection mixture from cold pipettes into each of several aerating, pre-warmed samples of MS + glucose to give a final temperature of 37° C. The time of dilution was considered to be zero time with respect to transcription because cells pulsed during the adsorption period did not incorporate tritiated uracil into T4-specific RNA. At various times after dilution, 0·3 mCi of 5-^{3}H-uridine or 6-^{3}H-uracil (New England Nuclear, 28·3 and 8·9 Ci/mmole, respectively) per 25 ml. of culture was added to one of the suspensions. Pulses were terminated 1 min after addition of tritium; collection of cells and extraction of RNA were as described by E. K. F. B. and Hall[11]. Subsequent procedures were essentially as described by K. T. and E. K. F. B.[1]. The columns contained r1272 DNA in the upper layer and rNB3034 DNA in the lower layer. The segment-specific RNA was tested in triplicate on r1272, rNB3034, rNB4906 (△), rNB2593 (×), rNB3162 (□), and r2045 (○) DNA filters. The percentage pure segment-specific RNA obtained was calculated as described[1]. This value multiplied by, for example, the fraction of the radioactivity (c.p.m.) on 4906–1272/3034–1272 filters gives the percentage of total hybridizable RNA homologous with nucleotide sequences of the rIIA cistron present in the DNA of deletion mutant rNB4906. Radioactivity retained on DNA filters was corrected for background by subtraction of counts on the blank filter. The times indicated were the times of termination of pulses.

Sequential Transcription of the rIIA Cistron

Studies on frameshift mutations in connexion with a mutant deleting the cistron divide between the rIIA and B cistrons have shown that the rII region is transcribed and translated from left to right on the genetic map, that is, in the direction of rIIA to rIIB[10]. We have attempted to determine the exact time at which different sections of the rIIA cistron are initially transcribed at 37° C in order (1) to confirm the genetic data, and (2) to estimate the time it takes an RNA polymerase molecule to read the rIIA cistron. Knowing the physical size of the rIIA cistron from electron microscopy of artificial heteroduplexes of r$^+$ and deletion DNA (H. Bujard, A. J. M., and E. K. F. B., manuscript in preparation), such an estimate would allow a calculation of the chain growth rate of RNA *in vivo*. Fig. 1 shows the relative amounts of rIIA-specific RNA found at different times after infection. The first rIIA-specific fragments found all hybridize both to DNA of a deletion mutant possessing only the first quarter of the rIIA cistron and to DNA of a mutant possessing most of this region, indicating that this RNA all came from the left end of rIIA (see insert, Fig. 1). Half a minute later, some rIIA-specific RNA is found which does not hybridize with the DNA of deletion mutants missing the right half of the rIIA cistron. From these data we estimate that it takes about 60 ± 10 s for the entire cistron to be transcribed. Because the length of the rIIA cistron is about 2,000 base pairs (H. Bujard, A. J. M., and E. K. F. B., manuscript in preparation), the chain growth rate is 34 ± 6 nucleotides/s at 37° C. This estimate lies between the 28 nucleotides/s reported for T4-infected cells[12] and a value of 43 nucleotides/s reported for uninfected *E. coli*[13].

An Early Promoter for the rIIB Cistron

The timing of transcription of the rIIA cistron is compatible with several alternatives, the two most likely being: (1) the function of the region to the left of rIIA is pre-early, and the polymerase which traverses this pre-early region continues to transcribe sequentially the early function rII genes, with the result that transcription of the rII region would be under the control of a pre-early promoter, presumably recognized by the *E. coli* σ factor. Alternatively, (2) transcription of the rIIA cistron is under the control of an early promoter, located near the left end of the gene, which is recognized by a new T4 σ factor. In the latter case, the approximately 80 s lag between the time of infection and the beginning of rII transcription would indicate the time required for the first T4 factors to be synthesized. (It is of interest to note that, according to our estimate of the RNA chain growth rate, the maximum size of a polypeptide which could be synthesized in this time span would be between 8×10^4 and 10×10^4 daltons, provided the transcription and translation proceed almost simultaneously.)

According to the first alternative, transcription of the rIIB cistron would necessarily have to commence only after completion of the first rIIA messengers, that is, the first rIIB-specific RNA fragments should not be found until about 2·25–2·5 min after infection. According to the second alternative, however, transcription of rIIB could start as early as that of rIIA if the B cistron has its own early promoter site. It was of interest therefore to see whether the rIIB cistron became transcribed before transcription of rIIA was completed. For this purpose we purified pulse-labelled RNA samples homologous to the DNA region missing in mutant rPB240 (or rPB28) but present in rNB3034. The RNA was tested for hybridizability with DNA of mutants rPB240 (or rPB28), r2045, and rNB3034 to determine what proportion of the RNA originated from approximately the right half (or right third) of rIIA and from rIIB (see insert, Fig. 2). Fig. 2 demonstrates that transcription of the rIIB cistron starts before the RNA polymerase has travelled halfway through the rIIA cistron; this can only be interpreted as indicating the existence of a separate promoter site serving the rIIB cistron. This promoter site is likely to be located between rIIA and rIIB because transcription of the entire chromosomal segment (including the distal D_2 region[1]) seems to proceed unidirectionally from left to right[10].

Some rIIA and rIIB Messengers are Polycistronic

Because of the evidence for the existence of a promoter site between the rIIA and B cistrons, we could expect that the two genes are transcribed separately, either mono-

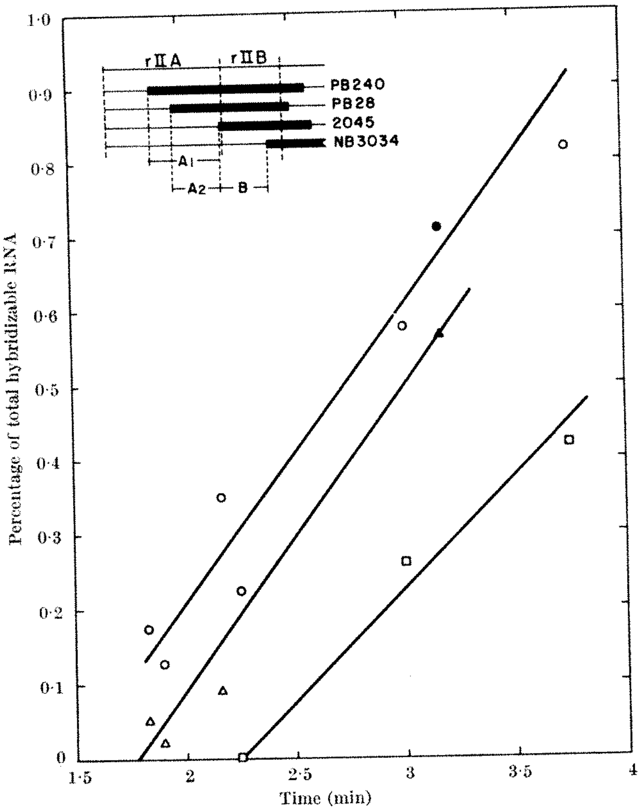

Fig. 2. Kinetics of transcription of adjacent portions of the rIIA and B cistrons. Procedures were as described in the legend to Fig. 1. Columns contained either rPB240 DNA in the upper layer and rNB3034 DNA in the lower layer, or were triple-layered, containing rPB28, r2045, and rNB3034 DNA, from top to bottom. DNA filters used were rPB240 or rPB28, depending on which DNA was used in the column, rNB3034, and r2045. The percentage of total hybridizable RNA corresponding to segment B is ○; segment A_1, △; segment A_2, □. Solid figures are the averaged results of duplicate determinations. The times indicated are times of termination of pulses.

cistronically or polycistronically with other adjacent genes. To test whether rIIA and B messengers are ever part of the same polynucleotide chain, we have done the experiment outlined in Fig. 3. RNA pulse-labelled from 2 to 5 min after infection was extracted by the hot phenol procedure[14] to obtain high molecular weight RNA. This RNA was passed through a double layer DNA column (step 1) containing DNA of the deletion r1272 in the upper and rPT8 in the lower column layer. RNA homologous with DNA of the B cistron should not find complementary sequences in either of the two layers and thus be lost from the column unless it were part of the same polynucleotide chain as rIIA RNA, which should be retained in the layer containing rPT8 DNA. The RNA eluted from rPT8 DNA with low ionic strength salt solution was then subjected to sonication (step 2) which produces 4S RNA fragments 60–100 nucleotides in length[1]. The fragments were then re-run through a second double layer DNA column (step 3) containing in the top layer a mixture of rA105 and r638 DNAs which feature all DNA sequences except those of the B cistron. RNA bound to r^+ DNA in the lower layer was, after elution, tested for hybridizability with rA105, r638, and r^+ DNA to determine how much of it is actually homologous with the rIIB cistron (Table 1). The RNA recovered from the bottom layer of column I (AI) represents 3 per cent of the total recovered from both layers: when applied after sonication to column II (AII), it is mostly retained on the upper layer, but 8 per cent of the recovered radioactivity was found in the bottom (r^+) DNA layer. Sixty-one per cent of this RNA hybridizes exclusively with rIIB DNA sequences, so that 0·15 per cent of the total RNA recovered from both columns is rIIB-specific. This result suggests that at least some rIIB messengers are synthesized contiguously with rIIA messengers. In a parallel experiment, half the original RNA was passed through a column (BI) containing rA105 DNA in the lower layer, allowing binding of B-specific RNA through overhang from both sides of rIIB (in case rIIB and D_1 messengers were contiguous). Here a larger amount of rIIB-specific RNA was retained, suggesting that most rIIB messengers are polycistronic with regard to D_1. It is possible, however, that the D_1 region is either not translated or is a dispensable part of the rIIB cistron, both possibilities being compatible with the fact that no mutations have been observed in it. Of the 0·76 per cent rIIB messengers found after column run BII, 0·47 per cent were found to be homologous with the right and 0·29 per cent with the left half of the rIIB cistron. This suggests that more rIIB-specific RNA was trapped on rA105 DNA in column BI by hybrid formation to D_1 than to rIIA. We interpret these data as indicating that transcription of only a fraction of the rIIB messengers originated at the same site which promotes transcription of the rIIA cistron.

Table 1. BINDING OF rIIB MESSENGERS TO DNA OF ADJACENT GENES

Column	DNA upper / DNA lower	RNA added to column (c.p.m. × 10^{-6})	Total RNA recovered on elution from both column layers (c.p.m. × 10^{-6})	RNA recovered from lower layer (per cent of total)
AI	r1272 / rPT8	15	10	3·0
BI	r1272 / rA105	15	12	4·1
		RNA recovered from r^+ layer (per cent of total)	Fraction of r^+ eluate which is rIIB-specific	rIIB-specific RNA (per cent of total hybridizable RNA, columns I and II)
AII	rA105 + r638 / r^+	8	0·61	0·15
BII	rA105 + r638 / r^+	21	0·88	0·76

An 80 ml. culture of *E. coli* B, grown to 5×10^8 cells/ml. at 37° C, was infected with 4 T4 r^+ phages per cell; after 2 min 1 mCi ^{3}H-uracil (specific activity 20 Ci/mmole) was added and the cells were harvested 5 min after infection. For subsequent steps, see text. DNA column runs and purity test were done as described[1], except that the total incubation time in the first column run was reduced to 8 h in order to minimize thermal degradation of the RNA.

Taking together the results of this and the previous section, it seems that part of the rIIB messengers are made by polymerases reading through from A to B, the rest being made by polymerases which initiate at the rIIB promoter. This suggests that a promoter which is in the path of transcribing polymerases does not necessarily have to act as a termination signal. The situation in which synthesis of messengers can apparently be initiated at more than one promoter site is not unique to T4-infected cells; an auxiliary weak promoter has been observed within the tryptophan operons of *S. typhimurium*[15] and *E. coli*[16]; an analogous observation was made with phage λ in that a low level of transcription of the S–R and A–J

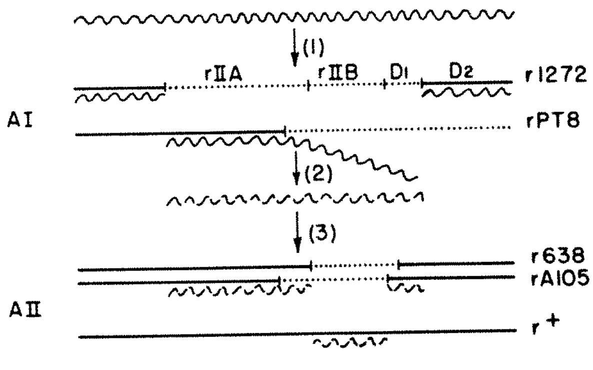

Fig. 3. Outline of experiment to test for polycistronic rIIB messengers. Experimental procedures are discussed in the text and Table 1.

Table 2. TRANSCRIPTION OF THE rII AND D REGIONS IN THE PRESENCE AND ABSENCE OF CHLORAMPHENICOL

Time of pulse (min)	CM	RNA added to column (c.p.m. × 10^{-6})	Total RNA recovered (c.p.m. × 10^{-6})	RNA recovered from T4W layer (per cent of total)	$\frac{\text{T4W}-222{\cdot}6}{\text{T4W}}.10^2$ (per cent purity)	P_t*	$\frac{1272-2226}{\text{T4W}-2226}.P_t$ (per cent D_2)	P_t–per cent D_2 (per cent rII + D_1)
1–2	–	20·7	10·4	7·28	95·5	6·9	5·2	1·7
3–4	–	29·3	11·8	9·25	95·9	8·9	1·8	7·1
1–2	+	14·7	4·0	8·89	97·6	8·7	8·7	0
3–4	+	12·9	3·4	6·28	97·8	6·1	6·1	0

* P_t = purity × per cent recovery from T4W layer.

The experiment was performed as described in the legend to Fig. 1, except that 100 μg/ml. chloramphenicol (CM, gift of Parke, Davis and Co.) was added to one-half of the culture 5 min before centrifuging the cells to prepare the infection mixture; these CM-treated cells were always in medium containing 100 μg CM/ml. during the experiment. The columns contained rNB2226 DNA in the upper layer and T4 wild DNA in the lower layer. DNA filters used to test the RNA were rNB2226, T4 wild, and r1272.

regions occurs in the absence of the Q gene product[17], which, if present, greatly enhances transcription of these late regions by recognizing at least one additional promoter between genes Q and S (I. Herskowitz and E. R. Signer, cited as personal communication in ref. 17). A similar situation seems to occur again in λ for the transcriptional process to the left of the N gene, where evidence for the functioning of auxiliary promoters superimposed upon the continued transcription from p_L leftward has been reported[17].

Are there more than Two Classes of Prereplicative Genes?

It was shown previously that maximal transcription is found between 0 and 2 min after infection for the D_2 region, between 1 and 3 min for the *e* gene, and between 4 and 6 min for the rII genes[1]. If chloramphenicol is added at or before the time of infection, transcription of only the pre-early D_2 region occurs and no rII or *e*-specific messengers are made (Tables 2 and 3). We could therefore argue that the D_2 region is under the transcriptional control of a pre-early promoter and that both rII and *e* genes are controlled by an early promoter which only responds to a phage-directed σ factor which is not made in the presence of chloramphenicol. It is difficult, however, to classify the rII genes and the *e* gene into one group because their patterns of transcription differ markedly. For example, the rII and *e* genes are similar in that neither is transcribed in the absence of protein synthesis and the first messengers of both regions appear at approximately the same time; but when the number of rII messages reaches a maximum level between 3 and 6 min, transcription of both the *e* and D_2 genes is approaching a minimum. Also, if we make adjustment for the difference in size between the D_2 and *e* genes, the number of messenger copies transcribed from these genes during this time interval is nearly the same but several-fold less than the number of rII messengers[1]. Finally, both *e* and D_2 regions are barely transcribed 20 min after infection with amBL292 (Table 3)—an amber mutant which fails to synthesize late messengers—whereas the early function rII genes are successfully transcribed in early amber mutants[1]. Thus while the transcription pattern of the typically early rII region differs markedly from that of the typically pre-early D_2 region, the pattern observed for the lysozyme gene is partly early and partly pre-early, depending on which criteria we apply for comparison.

Table 3. THE NUMBER OF LYSOZYME MESSENGERS PER CELL AT VARIOUS TIMES AFTER INFECTION

Infecting phage	Time of collection of cells (min after infection)	Number of *e* mRNA copies per cell – CM	+ CM*
T4 wild	3·5	12	0
	6·0	7	0
	15·0	20	0
amB22 (gene 43)	3·5	10	–
	8·0	3	–
	20·0	4	–
amBL292 (gene 55)	3·5	11	–
	8·0	4	–
	20·0	3	–

* 100 μg chloramphenicol/ml. of culture was added at time of infection.

Total RNA was prepared from infected cells collected at times indicated and increasing amounts were used for competition against a constant amount of ^{32}P-labelled lysozyme-specific RNA of high specific activity. The numbers of lysozyme messengers were calculated from the initial slopes of the competition curves. Experimental details will be published elsewhere (K. T. and E. K. F. B., in preparation).

To explain the peculiar transcription pattern of the *e* gene, we propose that the following mechanisms are involved in its early transcription. The *e* gene is located near a pre-early promoter. During the first minute after infection or at any time after infection in the absence of protein synthesis, the RNA polymerase which had initiated at this promoter fails to transcribe the *e* gene because of termination of transcription at a site located between the promoter and the *e* gene. This termination is probably performed by the host's ρ factor[9]. An accumulation of a phage-specified anti-terminator protein, about 1 min after infection, soon eliminates the termination signal and the RNA polymerase now reads into and through the *e* gene. While we have been able to show that there is a late promoter for the post-replicative synthesis of lysozyme messengers near the start of the *e* gene[1], we have no evidence for the existence of an early promoter specifically serving the *e* gene. Thus we propose that the indiscriminate action of the anti-terminator protein eliminates all transcriptional stops recognized by the ρ factor. Consequently, the early transcription of the *e* gene represents a "harmless accident" in the form of a continuation of transcription of a preceding pre-early gene. These early *e* messengers do not seem to be translated into functional lysozyme. We suggest that the initiating codon is not recognized by the translational machinery when the lysozyme message is contiguous with that of the preceding gene. This interpretation is in accord with the fact that an *in vitro* DNA-dependent protein synthesizing system produces functional lysozyme only in conditions of slight miscoding[18].

On the other hand, the fact that transcription of the rIIB cistron starts before the first rIIA messengers are completed can only be interpreted as proving the existence of an early promoter recognized by a σ factor different from the host σ factor. This result is not necessarily at variance with the finding of some contiguous rIIA and B messengers if we accept the existence of both mechanisms, that is, failure of chain termination plus new initiation within the rII region. The finding of substantially more rIIB messengers polycistronic with D_1 than with rIIA RNA (Table 1) actually indicates that not all rIIB messengers are linked with rIIA messengers. Termination between rIIB and D_2, however, must still occur with a high degree of efficiency, because no additional transcription of the pre-early D_2 region is observed at the time when the first polymerase molecules have finished transcribing the preceding rIIB and D_1 regions.

If indeed both the anti-terminator and the early T4 σ factor exist, we can expect to find, in addition to the pre-early genes, not one but two classes of early genes, namely those that are only transcribed together with pre-early genes through inhibition of termination and those which possess their own promoter sites for the T4 σ factor. The former class is expressed optimally within a very short time span (about 2 to 4 min, post infection), whereas expression of the latter class proceeds actively for a much longer time until it becomes gradually displaced by the transcription of late genes.

The postulated involvement of an anti-terminator and new promoter sites in the rigidly programmed expression of the T4 genome is not unique to this phage system; the N product of phage λ, for example, has been implicated as an anti-terminator to allow transcription to proceed further to the left and right of C_1 (ref. 17). In addition, there is evidence that the Q gene codes for a λ σ factor[19]. For T4 it is not yet possible to predict the relative contributions the anti-terminator and early T4 σ factor to the expression of all early genes. It is possible that their functions overlap almost completely at early times because no phage mutants have been reported to fail to express a significant part of their complement of early function genes.

Fusion of Isolated Plant Protoplasts

by
J. B. POWER
S. E. CUMMINS
E. C. COCKING

Department of Botany,
University of Nottingham

A first step towards somatic hybridization in plants has been achieved. Protoplasts have been isolated and seen to fuse.

We have devised controlled conditions in which plant protoplasts isolated from various species and tissues can be induced to fuse reproducibly. The significance of this lies in the potentiality for producing hybrid cells which combine plant genotypes that cannot be crossed sexually. Hybrid cells could be cultured to develop into complete plants, giving otherwise unobtainable hybrids which might be of great interest and value to pure and applied plant geneticists.

Much discussion has centred recently on the processes by which plant cells might be hybridized in laboratory conditions[1] and the principal stages are clear. First, protoplasts—cells with the wall removed—must be isolated from suitable tissue or from cell suspension cultures. Protoplasts are essential for hybridization so that the membranes of different cells can be brought into contact. Second, protoplasts must be induced to fuse in controlled and repeatable conditions to give heterokaryons. Third, the wall must regenerate round the fused protoplast, either before or after nuclear division. Fourth, the nuclei of the heterokaryons must fuse, probably during the simultaneous mitotic divisions, to give a true hybrid nucleus. Fifth, the resulting hybrid cells must then be taken into culture, and generation of intact plants induced. Regeneration of cell cultures from single species has often been observed. Of course, even given complete stability of the chromosome constituents, which may not be easy to achieve in culture, the simplest products of cell hybridization between different species would be an allotetraploid. For practical plant breeding purposes an extended breeding programme initiated from the vegetative hybrid would be necessary. Protoplasts have been seen to fuse before[2,3], but in ill-defined conditions, and fusions were rare and non-reproducible[4]. In these cases protoplasts were freed from their walls mechanically[5] and not enzymatically[6,7] as now. Initially the procedure required the plasmolysis of cells of mature tissues in hypertonic solutions of various kinds, and these conditions indicated some of the factors that affect the likelihood of protoplast fusion. For example, the presence of sucrose in the solution apparently inhibited fusion[2], while deplasmolysis often favoured its occurrence[3].

Conditions for Fusion

With conditions for the enzymatic isolation of protoplasts from meristematic[6,8] and mature tissue[9-11] of various plant species known, our problem was to find the conditions favouring fusion of protoplasts. It seemed likely that they could be determined by studying sub-protoplasts within intact plasmolysed cells. In some conditions plasmolysis is known to result in the formation of two sub-protoplasts, of approximately equal size, within the same cell wall. This occurs without rupture of the plasmalemma, and, of course, one sub-protoplast is nucleate and the other enucleate. Yoshida[12] showed that the two sub-protoplasts could fuse in suitable conditions. Large vacuolated cells of onion epidermis were plasmolysed in several solutions. The sub-protoplasts fused when they touched and the resultant protoplast expanded to fill the cell (details in Table 1).

Table 1. BEHAVIOUR OF SUB-PROTOPLASTS ON DEPLASMOLYSIS

Solution	Behaviour of protoplasts
0·56 M sucrose	Rarely fused after 4 h plasmolysis
0·5 M calcium chloride	Rarely fused after 4 h plasmolysis
1 M sodium nitrate	Mostly fused after 4 h and even after 24 h plasmolysis
1 M potassium nitrate	Rarely fused after 4 h plasmolysis
1 M sodium nitrite	Some slow fusion after 5 h plasmolysis
1 M sodium chloride	Some slow fusion after 5 h plasmolysis

When plasmolysis was carried out in either 0·56 M sucrose or 1 M sodium nitrate with 10 per cent cellulase (Onozuka) and 5 per cent 'Macerozyme' also present[9], sub-protoplasts only fused on deplasmolysis when 1 M sodium nitrate had been present. And so sodium nitrate apparently favoured fusion, but we had to check whether this was also true of isolated protoplasts freed from the cell wall. To do this we isolated protoplasts mechanically from onion epidermal cells, after initial plasmolysis in appropriate solutions using Plowe's method[13]. Protoplasts were manipulated in a cavity slide, being pushed together with micro-needles made from 0·2 mm diameter glass capillary tubing. After this either protoplasts adhered to one another, apparently fusing, and could not be pulled apart, or they drifted apart when the slide was subjected to any slight movement.

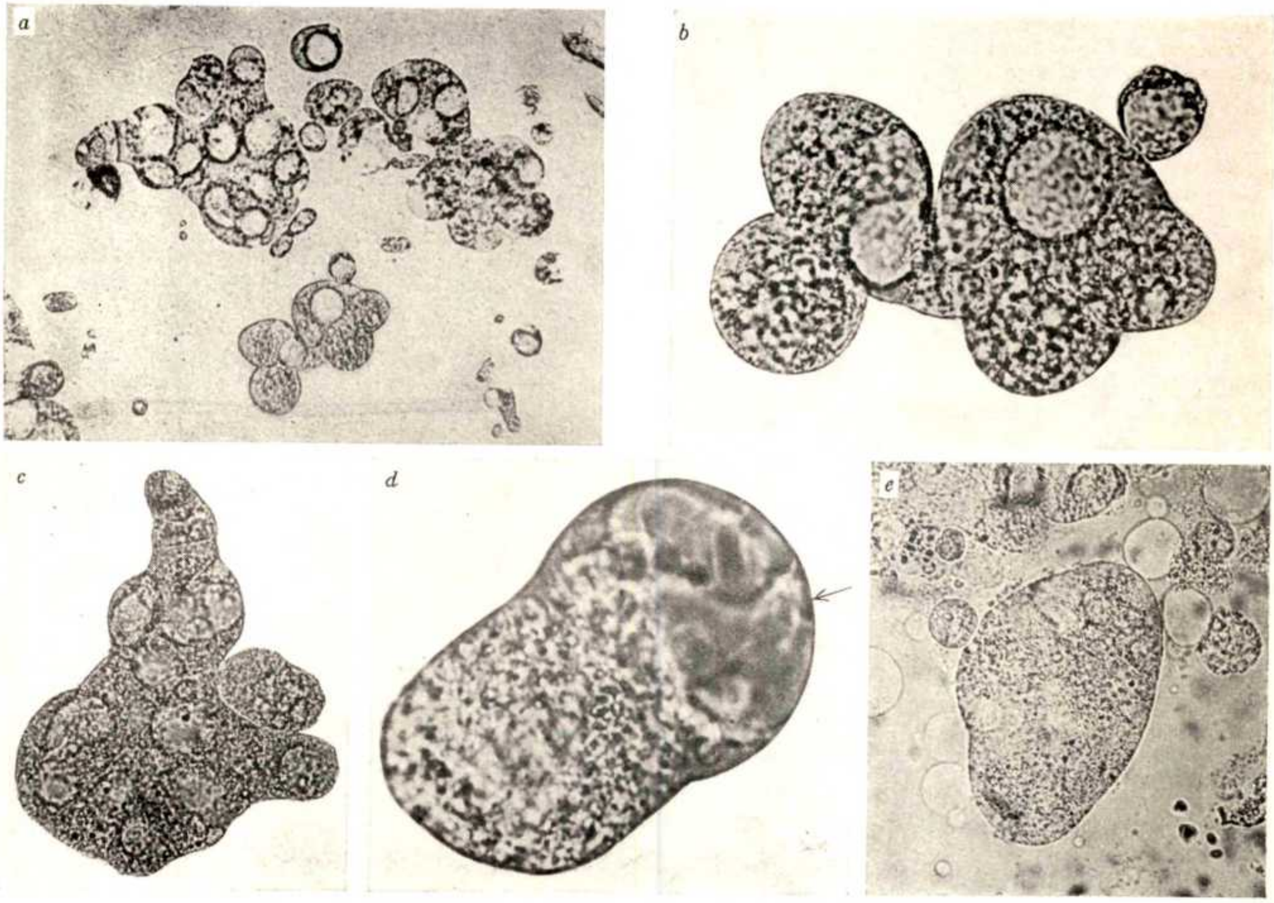

Fig. 1. *a*, Fusion of isolated protoplasts from oat root following treatment with 0·25 M sodium nitrate (×55); *b*, higher magnification of the fused protoplasts from *a* showing protoplast fusion, plasmalemma disappearance, and cytoplasm coalescence. Note presence of vacuoles within the cytoplasm (×175); *c*, another fused protoplast from *a* showing the more complete mergence of protoplasts. Note presence of vacuoles within the cytoplasm (×100). *d*, Fusion of a non-vacuolated meristematic protoplast from oat root with a vacuolated protoplast of a maize lateral root (arrowed) after treatment with 0·25 M sodium nitrate (×380). *e*, Spontaneous fusion body emerging from the oat root tip (×*c*. 117).

Fusion Achieved

When the plasmolyticum was 0·56 M sucrose and protoplasts had been in the sucrose solution for 1 h, no adhesion of the isolated protoplasts was observed. But when 0·25 M sodium nitrate was used as the plasmolyticum protoplasts of different sizes readily adhered and apparently fused. Over-plasmolysis, which resulted when 1 M sodium nitrate was the plasmolyticum, was detrimental to fusion.

When the cells were first plasmolysed in 0·56 M sucrose and the protoplasts were then isolated and placed in 0·25 M sodium nitrate, fusion occurred immediately. This resulted in the formation of several aggregates of fusing protoplasts, and there was a greatly enhanced tendency for protoplasts to adhere in these conditions.

Protoplasts have been isolated in this laboratory before, using pectinase, cellulases or mixtures of pectinase and cellulase in 0·56 M sucrose from such various plant tissues as mature tomato fruit[7], leaf tissue of tobacco[9] and radish storage root. These mature protoplasts are usually highly vacuolated, and only rarely has there been any semblance of fusion. Moreover, the peripheral alignment of chloroplasts or other plastids seems to be detrimental to fusion when sucrose is the plasmolyticum.

Thus it seemed that meristematic protoplasts isolated enzymatically from seedling tissues or tissue cultures would be most suitable for fusion studies. Surface sterilized seeds of oat, maize, wheat, barley and rice were germinated aseptically in the dark at 22° C. The excised tips of roots approximately 2–3 cm long were incubated for 24 h at room temperature on a glass slide with a few drops of the enzyme mixture (which had been filtered through 'Millipore' and contained 10 per cent (w/v) cellulase (Onozuka P1500) and 5 per cent (w/v) 'Macerozyme' in 0·56 M sucrose). Incubation was terminated by removing excess enzyme mixture and then twice washing each root tip with 0·25 M sodium nitrate. After the second wash 0·25 M sodium nitrate was added to cover each root tip and a cover slip was gently lowered onto the specimen. The pressure released numerous protoplasts from the meristematic region of the root tip and from the more vacuolated region. They floated free into the surrounding sodium nitrate solution; there was slight deplasmolysis at this molarity of sodium nitrate. During the next hour we observed fusion of the meristematic with vacuolated, meristematic with meristematic, and vacuolated with vacuolated protoplasts. Protoplasts first came into contact, adhered and subsequently were seen to fuse and gradually merge as a result of the disappearance of the two closely adpressed plasmalemmae. Initially, and particularly when several protoplasts were seen to fuse together, multi-lobed structures were evident (Fig. 1*a*, *b* and *c*); only later did these fused protoplasts round off. It was difficult to see nuclei during this progressive coalescence of the cytoplasm of adjacent protoplasts; sometimes fusion of the vacuoles was observed.

When root tips, after incubation with the enzyme mixture, were washed with 0·3 M sucrose, which was isotonic with 0·25 M sodium nitrate, and the cover slip was added, we could detect no fusion of the freely floating protoplasts from the meristematic region or the more vacuolated region.

Inter-species Fusion

Preliminary indications of the possibility of inter-species fusion were obtained using protoplasts from oat and maize. Portions of the meristematic region of oat roots and the vacuolated tissue from the root tip of maize (lateral roots) were incubated side by side with the enzyme mixture as described before. They were then washed twice with 0·25 M sodium nitrate, and a cover slip was gently lowered onto them. Contrasting protoplasts were released from the two tissues and fused with each other (Fig. 1*d*). More extensive and larger scale inter-species fusion of isolated protoplasts is being investigated using the culture chambers described by Pojnar and E. C. C.[14], which readily allow protoplasts to be pushed together while floating freely in sodium nitrate solution.

Similar fusion of protoplasts isolated from tobacco callus (*Nicotiana tabacum* var. P19) using a cellulase and 'Macerozyme' mixture has also been observed. It has also been found possible in this laboratory to isolate protoplasts from both cereal root tips and tobacco callus using a considerably purer enzyme preparation than that from Onozuka—purified *Trichoderma viride* cellulase (Miles Laboratories Inc.)—with the added 'Macerozyme' or pectinase; and it is known that it is possible to isolate tomato fruit protoplasts using a purified pectinase[15]. These findings should facilitate further studies of the cell wall regeneration and nuclear division of fused protoplasts, for, as discussed before[9], the use of such purified mixtures of cell wall degrading enzymes will probably be essential for cell wall regeneration and subsequent division. It should be noted that when mechanically isolated moss protoplasts are maintained in culture, cell wall readily regenerates, and whole plants readily form after protonemata have developed[16]. Eriksson[17] has reported limited nuclear division of enzymatically isolated protoplasts from *Haplopappus* and also some evidence of cell wall regeneration.

Protoplast fusion of the type we have described must not be compared with the development of the spontaneous fusion bodies formed after wall degradation within the cell symplasm of any tissue (Fig. 1*e*). These consist of two or more morphologically similar protoplasts, and, although they occur when isolation is carried out using an enzyme mixture in 0·56 M sucrose followed by washing with 0·3 M sucrose, they are much more frequent when enzyme treatment in 0·56 M sucrose is followed by washing with 0·25 M sodium nitrate. Similar fusion bodies have also been observed during the isolation of soybean protoplasts (O. Gamborg and R. Miller, personal communication). Such fusions are of little practical significance in that they always occur between protoplasts from a single tissue, whereas the fusion of isolated protoplasts from different tissues and species in the way we have described may provide entirely new genetic situations.

Value of Totipotency

Isolated meristematic protoplasts of plants seem closely to resemble cultured animal cells. By contrast with animal cells, however, the totipotent nature of plant cells[18] will now enable attempts to regenerate whole plants from inter-species heterokaryons and from the true hybrid cells that may be obtained ultimately. It is interesting that no added virus, such as inactivated Sendai virus, is required for the reproducible and controlled fusion of isolated plant protoplasts, although this has been necessary for the extensive fusion of animal cells in culture[19]. It is difficult to explain the action of sodium nitrate in inducing fusion, following plasmolysis of plant protoplasts in sugars such as sucrose. But changes in the electrical properties of the plasmalemma are probably involved, for there is a close parallel between the fusion phenomenon we have observed and the well known effect of sodium ions on the electrical excitability of frog muscle after treatment with sucrose, glucose or mannitol[20]. Furthermore, because freely isolated vacuoles are known to fuse[21] when maintained in sucrose, it may well be that the surface charge and fusion characteristics of the tonoplast differ from those of the plasmalemma.

Although continued examination of protoplast fusion is necessary, we now know that it can be achieved readily. The next stage in the development of procedures for the somatic hybridization of plants must be the study of the enzyme systems involved in cell wall degradation, and regeneration after protoplast fusion. It may, for example, be necessary to use competitive substrates for the effective removal of adsorbed enzymes from the protoplast. Whatever the outcome of future investigations it is nevertheless true that the two first steps towards the production of somatic plant hybrids can be taken. Protoplasts can be isolated in a state that allows fusion and interspecific fusions can take place.

Ethylene, the Natural Regulator of Leaf Abscission

by
MICHAEL B. JACKSON
DAPHNE J. OSBORNE
Department of Agricultural Science
and ARC Unit of Experimental Agronomy,
University of Oxford

Natural leaf fall is triggered by increased ethylene production in senescing cells close to abscission zones.

ETHYLENE is increasingly thought of as an integral part of plant auto-regulation[1]; a concept originating from the discovery that ethylene was a natural product of plant metabolism[2,3]. More recently, the use of gas chromatography has shown that many plants can synthesize the gas, and a precise control mechanism involving ethylene has been described for plumular hook opening in the germinating pea seedling[4]. Although ethylene has been shown to be a potent accelerator of leaf abscission, there is no clear evidence correlating the pattern of ethylene production *in vivo* with the control of abscission. Indeed, Abeles[5] has concluded that the timing of abscission is determined not by changes in the rate of production, but rather by an increase in the sensitivity of the tissue to ethylene.

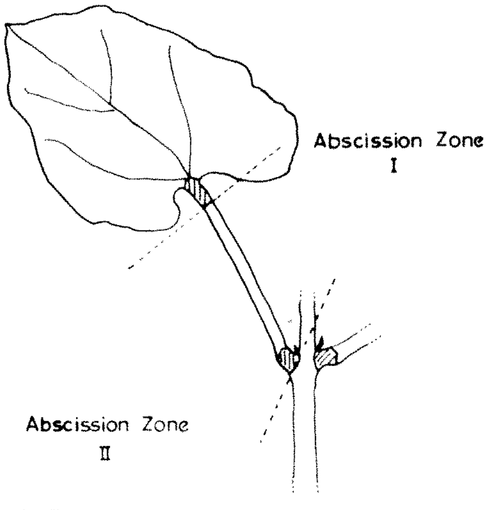

Fig. 1. The two abscission zones of a primary leaf of *Phaseolus vulgaris* (L).

Excised abscission zones (explants) are widely used in studies of abscission[5,6], and are usually kept in closed containers at high humidity. Our results show that unless precautions are taken to avoid accumulation of ethylene in the containers, the time of abscission is artificially accelerated and the relationship between ethylene production and abscission is obscured. Here we report experiments in which the ethylene produced was removed continuously by chemical absorption. They reveal a clear relationship between abscission and ethylene production. These and other experiments demonstrate that an increase in the rate of ethylene production after the onset of sensitivity to ethylene can be closely correlated with the time of abscission.

The plant material chosen for much of this work is similar to that used in previous studies of abscission[6]. Plants of *Phaseolus vulgaris* (L), variety 'Canadian Wonder', were grown for 14–18 days in a greenhouse with supplementary lighting. Tissue was taken from the first and second abscission zones of the primary leaves (Fig. 1) and the patterns of ethylene production and timing of abscission studied. Tissue was removed from the first abscission zone either as segments (explants) 1 cm in length and including the whole pulvinus, petiole tissue and the abscission zone, or as individual segments of pulvinus and petiolar tissue. Excised second abscission zone material consisted of stem, pulvinar and petiolar segments. We also studied the ethylene production in petioles from *Prunus serrulata senriko* (Lindl.) and *Parthenocissus quinquefolia* (Planch).

We first describe experiments with explants from abscission zone I. Twenty such explants were placed in 15 ml. Erlenmeyer flasks and sealed with plastic vaccine caps. They were used for (*a*) treating explants with ethylene, (*b*) following the visual progress of separation, and (*c*) collecting evolved ethylene. Concentrations of ethylene were estimated by flame-ionization gas chromatography every 12 h, or more frequently when required. The progress of abscission was followed in explants incubated in the presence or absence of an ethylene absorbant. For this purpose a tube containing 1 ml. of 0·2 M mercuric perchlorate in 0·2 M perchloric acid was inserted into each flask, obviating the artificial accumulation of gas in the collection flasks and within the explants. Flasks were kept in the dark at 25° C and, after each determination, ventilated with compressed air and resealed. After abscission, petiolar and pulvinar pieces were separated and their ethylene production determined independently. The patterns of abscission and ethylene production both before and after abscission are shown in Fig. 2*a*. The important features are: (1) a high rate of ethylene production confined to the first 12 h after excision; (2) a subsequent period of low ethylene production ($< 0{\cdot}25$ nl./g/h) lasting for some 90 h; towards the end of this period abscission takes place in explants incubated without mercuric perchlorate; (3) a later period of high ethylene production lasting about 90 h during which explants in the presence of mercuric perchlorate abscind at point X (Fig. 2*a*). Fig. 2*a* shows that most of this ethylene, produced between 100–190 h, is synthesized by the pulvinus while production by the petiole remains low. The petiole does, however, produce a peak of ethylene, at a later time (Fig. 2*b*). We suggest that the ethylene peaks shown in Fig. 2*b* are a feature of the tissues at a particular stage of senescence. It is already known that senescence in petiolar tissue is slower than that of the pulvinus. For example, the ability to synthesize new protein after excision falls more rapidly in the pulvinus than in the petiole[6].

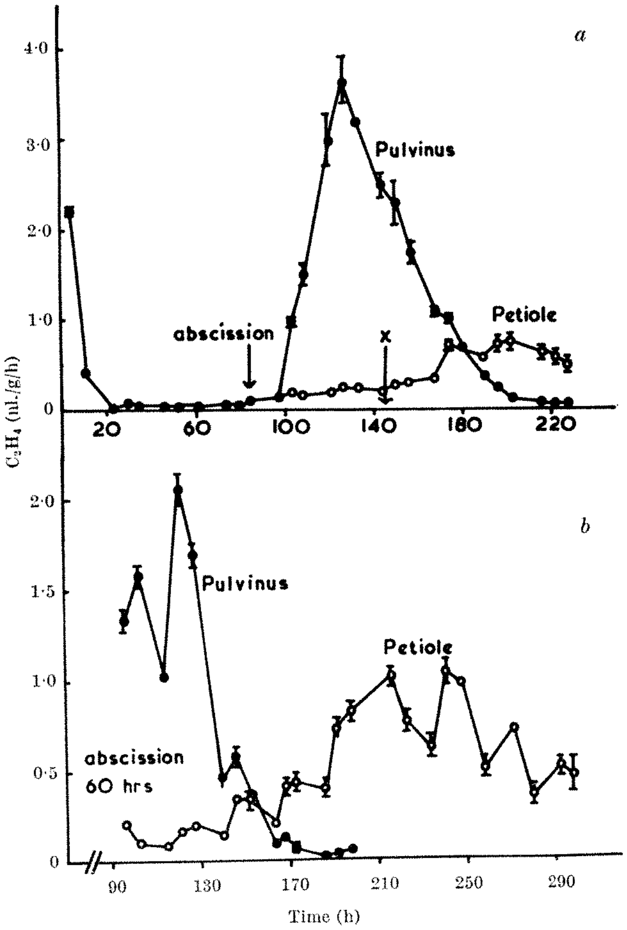

Fig. 2. *a*, Ethylene production by abscission zone I explants of *Phaseolus vulgaris* (L), before and after abscission. (Incubated in the absence of 1 ml. 0·2 M mercuric perchlorate.) Point X shows the time of abscission for explants incubated *with* 0·2 M mercuric perchlorate. *b*, Ethylene production by the petiole and pulvinar parts of explants during a later period (vertical lines represent *S.E.*). 1 ml. gas samples were withdrawn from collection flasks and injected into a Pye 'series 104' gas chromatograph fitted with a hydrogen flame ionization detector. The 61 cm glass column contained 7·5 g of 100–150 mesh activated silica gel and carried nitrogen flowing at 21·5 ml./min. Authenticity of the ethylene peak was determined using ethylene standards, retention times and mercuric perchlorate absorption. The concentrations of injected ethylene were proportional to peak height over the concentration ranges measured. At a column temperature of 132° C the retention time for 1 nl. of ethylene was 85 sec. Values above 0·04 nl./ml. could be accurately determined and lower levels detected. The results are expressed as nl./g (fresh) wt/h.

We interpret the results of Fig. 2 in the following way. The abscission time observed 80 h after excision is certainly an artefact resulting from the accumulation of ethylene in the flasks between ventilation times, for if ethylene is removed by mercuric perchlorate absorption, separation does not occur until 140–150 h (point X). Ethylene production by the pulvinus is then high (3·0 nl./g/h) and sufficient to raise the concentration of ethylene within the explant to abscission promoting levels. Results of experiments on the pattern of explant sensitivity to ethylene support and extend these interpretations.

The effects of supplying ethylene for precise intervals were determined as follows. Explants were incubated in the presence of mercuric perchlorate as described before. Every 12 or 24 h two flasks of twenty explants were selected at random and treated with 2 p.p.m. ethylene for two consecutive 12 h periods by removing the mercuric perchlorate and injecting through the vaccine cap. The results in Table 1 demonstrate the following points. Abscission is not accelerated by the added ethylene during the first 24 h after excision. After this period of insensitivity, explants become fully sensitive to ethylene and remain sensitive *throughout* the subsequent 132 h incubation with mercuric perchlorate. Abscission can be induced during the period of low ethylene production (24–100 h, Fig. 2*a*) by any 24 h period in 2 p.p.m. ethylene (Table 1). The low production between 24 and 100 h is alone insufficient to cause abscission, even though the tissue is sensitive to ethylene. Abscission can occur during this time only if ethylene is left to accumulate in the flasks or if additional ethylene is supplied. In the presence of mercuric perchlorate (Table 1), abscission occurs at 156 h; separation at this time can be correlated causally with the rise in ethylene production by the pulvinus commencing some hours before.

Table 1. EFFECTS OF SUPPLYING 2 P.P.M. ETHYLENE AT DIFFERENT TIMES ON THE SEPARATION OF EXPLANTS (*Phaseolus vulgaris* (L))

Ethylene treatment time (h)	Time to 50 per cent separation (h)
0– 12	144
12– 24	144
12– 36	48
24– 48	48
36– 60	60
48– 72	60
60– 84	71
72– 96	96
96–120	120
120–144	144
No ethylene	156

When not exposed to ethylene, the explants were enclosed with 0·2 M mercuric perchlorate in 0·2 M perchloric acid.

Ethylene produced during the first 12 h after excision was found to have no influence on the time of abscission, and therefore will be discussed only briefly. Precise measurements during the first 24 h show that ethylene production rises steeply after half an hour, is greatest by 1·5–2·0 h and then declines to a basal level after 12 h (Fig. 3). That the eighteen-fold maximum is reached only after 1·5–2·0 h shows that this is not a sudden release of accumulated ethylene from the tissue but is most probably a wound response. The amount of ethylene produced can be shown to be directly related to the extent of cutting (wounding). Pieces of 2 cm petiole, sliced into one, two or three pieces to expose two, four or six cut surfaces, synthesize amounts of ethylene proportional to the number of cuts made. In one experiment the rates of production of ethylene in the first 2–4 h period were

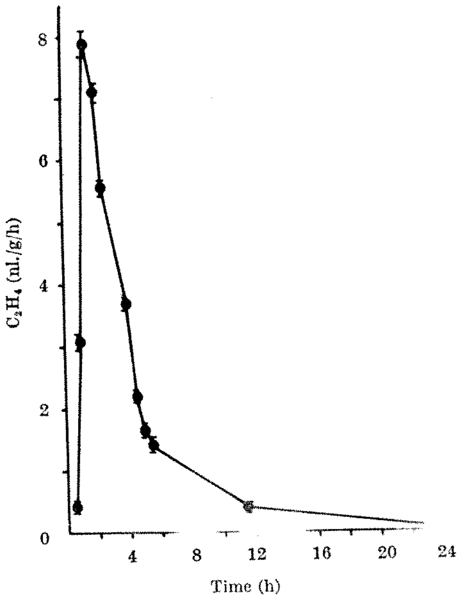

Fig. 3. Ethylene production during the first 24 h after excision of abscission zone I explants of *Phaseolus vulgaris* (L). (Vertical lines represent *S.E.*)

2·94 (±0·01), 6·85 (±0·63) and 8·38 (±0·78) nl./g/h respectively.

To determine whether the wound ethylene is involved in timing abscission in explants, the build-up of ethylene was permitted or reduced during the time of wound ethylene production. Explants were enclosed in collection flasks with 1 ml. vials of 0·2 M mercuric perchlorate. In this way, by securing the maximum possible diffusion gradient between the enclosed tissue and the surrounding atmosphere in the flasks, a reduction in the endogenous level of ethylene within the explant was possible. By omitting or supplying mercuric perchlorate for strategic intervals, it was possible to assess the activity of the wound ethylene. Treatments designed to reduce concentrations of ethylene in the tissue during the first 24 h after excision fail to delay separation when compared with control *A* (Table 2). Similarly, treatments that allow the maximum possible build-up of the wound ethylene in the tissue during the same period do not promote separation when compared with the appropriate control *B* (Table 2). We therefore conclude that the potentially interfering production of wound ethylene does not influence abscission in these explants. Further, applied ethylene does not promote separation unless administered 24 h after excision (Table 1), suggesting again that abscission of the explant is not regulated by any ethylene present before about 24 h have elapsed. In other words, the explant possesses an initial period of insensitivity to ethylene.

Table 2. EFFECTS OF ABSORBING WOUND ETHYLENE WITH 0·2 M MERCURIC PERCHLORATE IN 0·2 M PERCHLORIC ACID ON THE SEPARATION OF EXPLANTS (*Phaseolus vulgaris* (L.))

Treatment	Time to 25 per cent separation (h)
No absorption of ethylene (control *A*)	72
Absorption of ethylene 0–12 h	72
Absorption of ethylene 12–24 h	72
Absorption of ethylene 0–24 h	72
Continuous absorption of ethylene (control *B*)	144
No absorption of ethylene 12–24 h	> 144
No absorption of ethylene 0–24 h	144

We have obtained direct evidence that a rise in ethylene production precedes the normal shedding of leaves. Ethylene was collected from tissue excised from bean plants at three different ages: stage 1, plants entirely non-senescent; stage 2, plants with yellowing primary leaves but showing no sign of abscission; stage 3, plants with yellow primary leaves readily detached by light pressure. The whole pulvinus and a 1 cm piece of adjoining petiole were removed separately from abscission zone I. The whole pulvinus, 0·5 cm of adjoining stem and 1 cm of adjoining petiole were removed separately from abscission zone II. Ethylene production by these pieces was monitored in the usual way and the results are shown in Figs. 4 and 5. In first abscission zone tissue the non-senescent petiole and pulvinus produce only very small amounts of ethylene after the initial wounding effect. Ethylene production by these pieces from the yellowing but non-abscinding primary leaves was much greater and increased during the course of the experiment, while post-abscission material produced large but declining concentrations of ethylene. A rise in ethylene production by tissues surrounding the first abscission zone therefore occurs before abscission, and the rate declines only when separation is complete. Results for abscission zone II are very similar to those described for abscission zone I (Fig. 5). Ethylene production by petiolar and pulvinar tissue distal to the abscission zone rises only when the leaves are yellowing and before separation; production by these tissues falls only after separation is complete. There is no change in the rate of ethylene production by stem tissue proximal to the zone; the rate remains low at 0·07–0·11 nl./g/h throughout.

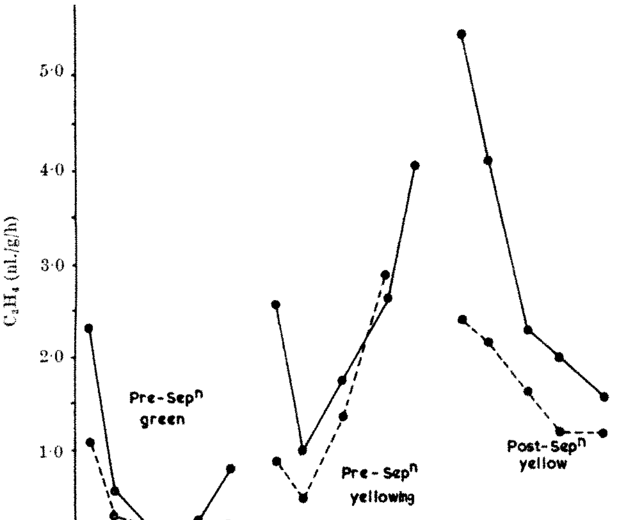

Fig. 4. Ethylene production by segments of petiole (● - - - ●) and pulvinus (●—●) adjacent to abscission zone I taken from primary eaves of *Phaseolus vulgaris* (L) at three ages: (1) pre-separation, non-senescent (green); (2) pre-separation senescing (yellowing); (3) post-separation, senescent (yellow).

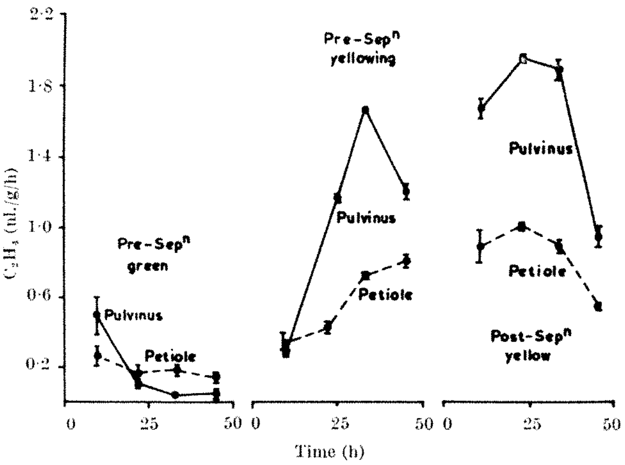

Fig. 5. Ethylene production by segments of petiole and pulvinus adjacent to abscission zone II taken from primary leaves of *Phaseolus vulgaris* (L) at three ages: (1) pre-separation, non-senescent (green); (2) pre-separation, senescing (yellowing); (3) post-separation, senescent (yellow).

The correlation between abscission and a rise in ethylene production has been extended to two deciduous woody species, *Prunus serrulata senriko* and *Parthenocissus quinquefolia*. Petiole segments from *Prunus* leaves in a green non-senescent state firmly attached to the tree, or in a yellow senescent state readily detached from the tree, were removed and enclosed in separate ethylene collection flasks. The quantities of ethylene produced were measured during a period of 135 h and are illustrated in Fig. 6. Ethylene production by yellow post-abscission petioles falls throughout the experiment. Production by the green pre-abscission petioles rises sharply after a period of low production, reaches a well defined maximum as the tissue becomes yellow and then declines. This situation is clearly very similar to that described for *Phaseolus*. Both species are readily defoliated by ethylene, both show a senescence related rise in ethylene production a short time before separation and a falling rate when separation is complete. Comparable but less extensive data are available from experiments with *Parthenocissus*. Concentrations of ethylene produced by petiole tissue adjacent to the proximal abscission zone in this species

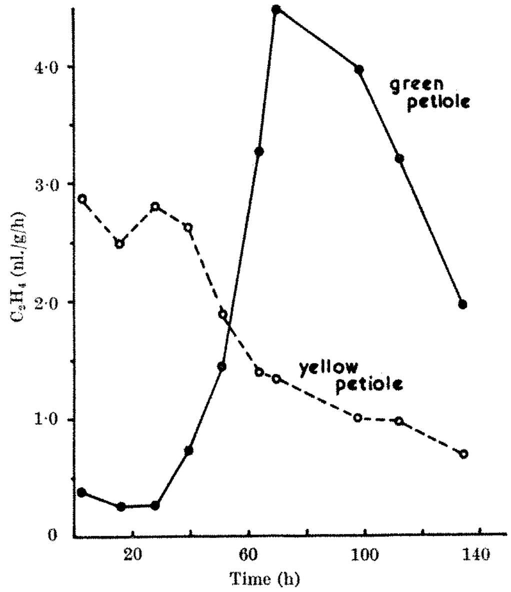

Fig. 6. Ethylene production by 2 cm petiole segments of *Prunus serrulata senriko* taken from leaves at two ages: (1) green—non abscinding; (2) yellow—abscinding. Sampled October 14, 1969.

are thirteen-fold higher at the time of abscission than some days before (Table 3). The results also show that most ethylene is produced by tissue close to the abscission zone, emphasizing again the importance of tissue adjacent and distal to the separating cells.

We present critical evidence that the timing of foliar abscission can be precisely related to the extent of ethylene production adjacent to the separation zone. In isolated abscission zones of *Phaseolus* (explants), so frequently used in abscission experiments, incubation techniques have hitherto obscured the role of endogenous ethylene production in the regulation of abscission. If accumulation of ethylene is precluded a clear relationship between increased ethylene production and abscission is obtained. No such accumulation occurs during natural leaf abscission in the open. In the three species studied, large quantities of ethylene are synthesized shortly before leaf fall in tissues adjacent to the zone of separation. We suggest that this ethylene production occurs when a particular stage of senescence is reached and that the ethylene initiates the biochemical sequences[6] responsible for separation.

Table 3. ETHYLENE PRODUCTION BY 1 CM SEGMENTS OF PETIOLE ADJACENT TO THE PROXIMAL ABSCISSION ZONE FROM THE LEAVES OF *Parthenocissus quinquefolia* (PLANCH) AT TWO STAGES: (1) PRE-ABSCISSION; (2) ABSCINDING

Time (hours)	Stage	Ethylene nl./g/h (± *S.E.*) Distance from the abscission zone		
		2–3 cm	1–2 cm	0–1 cm
0–12	Pre-abscission	0·08 ± 0·02	0·09 ± 0·02	0·06 ± 0·02
	Abscinding	0·47 ± 0·10	0·60 ± 0·13	0·82 ± 0·03

Effects of Actinomycin D and Cycloheximide on RNA and Protein Synthesis in Cleavage Stage Mouse Embryos

by
RICHARD J. TASCA*
NINA HILLMAN
Department of Biology, Temple University, Philadelphia, Pennsylvania

In the earliest stages of the development of mouse embryos, RNA synthesis can be blocked without inhibition of protein synthesis; but stopping protein synthesis depresses RNA synthesis.

THERE have been several reports on the effects of actinomycin D on the morphological development of cleavage stage mouse embryos[1-4]. These studies show that low concentrations of actinomycin D ($1-2 \times 10^{-4}$ μg/ml.) have no effect on the rate of cleavage or on blastocyst development. Intermediate concentrations (6×10^{-4} to 1×10^{-3} μg/ml.) do not interfere with cell division during cleavage but prevent blastocyst differentiation (expansion, elongation, hatching) when the antibiotic treatment begins at the late four cell or older stages. Cells of embryos treated with higher concentrations ($> 0·08$ μg/ml.) undergo no more than one additional mitotic division before development is arrested.

Autoradiographic and cytochemical studies have shown that intermediate concentrations of actinomycin D cause a reduction of nucleolar RNA synthesis, while higher concentrations reduce, or block, all nuclear RNA synthesis[2]. There is only a slight reduction of protein synthesis as a result of these treatments. The sensitivity of cleavage stage embryos to a protein synthesis inhibitor (puromycin) has been described[1]. These studies show that there is a correlation between the dosage of puromycin and the stage at which development is blocked. There have been, however, no detailed biochemical analyses to determine the effects of antibiotics on RNA and protein syntheses during early mouse development. The present study reports the effects of actinomycin D and cycloheximide on the rates of RNA and protein synthesis in two cell to morula (sixteen to thirty-two cells) stage mouse embryos.

For this study, large numbers of synchronously developing, two cell embryos were obtained from 10–12 week old superovulated[5] albino females which had been mated to albino males. The embryos were placed in mouse embryo culture medium[6] in which they developed from the two cell stage to the blastocyst (more than thirty-two cells) stage in approximately two days. The two cell embryos were allowed to develop to specific cleavage stages and were then incubated in either ^{3}H-5-uridine (6 μCi/ml., 20–25 Ci/mmole, Schwartz) or in ^{14}C-leucine (0·6 μCi/ml., 170–200 mCi/mmole, Schwartz) for a 3 h period in the presence or absence of actinomycin D or cycloheximide. The embryonic stages treated were: late two cell (L2); late two cell–early four cell (L2E4); early four cell (E4); late four cell (L4); eight to sixteen cell; and late morula (LM, sixteen to thirty-two cells). After the 3 h incubation those embryos to be used for biochemical studies were counted, rinsed four times with culture medium, collected in 20 μl. of Earle's BSS, frozen in solid CO_2 and acetone and stored at −70° C. The remaining embryos were washed, placed into unlabelled culture medium and allowed to continue development so that the effects of the drugs on development could be determined. Each experiment was repeated at least three times.

---

* Present address: Department of Biological Sciences, University of Delaware, Newark, Delaware 19711.

A modified Schmidt–Thannhauser[7] technique was used for extracting the embryos. After thawing the embryos, 25 μl. of cold distilled water was added, and the embryos were ruptured by four freeze–thawings. Cold 1·6 M perchloric acid (PCA) was added to obtain a final concentration of 0·3 M PCA. This treatment was followed by ribonuclease (0·2 per cent) digestion of the acid-insoluble precipitate and then hyamine hydroxide digestion of the residual ribonuclease resistant pellet. All centrifugations were performed at 13,000 r.p.m. for 20 min and all precipitates were washed twice. These steps provided the following three fractions: acid soluble; acid insoluble, ribonuclease sensitive (RNA fraction); acid insoluble, ribonuclease resistant, hyamine hydroxide soluble (protein fraction). The amount of label contained in each fraction was determined by liquid scintillation counting. The total of the counts of the acid soluble fraction (unincorporated precursor), RNA fraction and protein fraction accounts for all of the radioactive label which enters the embryos and is designated as ^{3}H-5-uridine uptake or ^{14}C-leucine uptake.

In initial experiments it was found that the ^{3}H-5-uridine uptake (in c.p.m./100 embryos) increased by three-fold between the L4 stage and eight to sixteen cell stage, and by four-fold between the eight to sixteen cell stage and morula stage (Fig. 3). For this reason, the rates of RNA and protein synthesis are here expressed as "percentage incorporation", or the total number of counts in the RNA or protein fraction/total uptake of precursor × 100. The data are expressed as percentage incorporation so that syntheses of different stages may be compared despite permeability differences which may be reflexions of changes in the endogenous precursor pool sizes (not yet determined in mouse embryos). Treating the data in this way, it was found that the rates of synthesis are characteristic for each stage, for the percentage incorporation does not fluctuate significantly when the uptake of the precursors is changed by incubating the embryos with different amounts of radioactivity: ^{3}H-5-uridine (1·5–25 μCi/ml.) or ^{14}C-leucine (0·3 to 0·6 μCi/ml.).

The rate of RNA synthesis increases progressively in cleavage stage mouse embryos from 8 per cent at the late two cell stage to 30 per cent at the morula stage (RNA controls, Fig. 1). The largest increase (9 per cent) occurs between the eight to sixteen cell stage and the morula stage. Recently, it was reported that high molecular weight RNA synthesis is detectable as early as the two cell stage, and ribosomal RNA (rRNA) synthesis at the four cell stage[8]. Moreover, rRNA synthesis has been shown to increase at the eight cell and morula stages[9]. The increases can be correlated with a progressive hypertrophy of the pars granulosa of the nucleoli at each successive developmental stage[10]. Granular nucleoli are first present at the L2 stage, suggesting that part of the RNA which is synthesized at this stage is rRNA or rRNA precursor molecules.

Evidence which supports the above findings, that rRNA is synthesized in early mouse embryos, is provided by actinomycin D experiments (Fig. 1). Actinomycin D (0·0008 μg/ml.) reduces the rate of RNA synthesis at all stages. The rate of synthesis is reduced slightly at the L2–E4 stage (approximately 2 per cent). This reduction becomes greater through the cleavage stages until the morula stage when the percentage incorporation is about 14 per cent (16 per cent reduction from the normal value). Because low concentrations of actinomycin D preferentially inhibit rRNA synthesis[11], it is probable that most, if not all, of the mouse embryo RNA synthesis which is inhibited by 0·0008 μg/ml. actinomycin D is rRNA. Although this concentration of antibiotic allows embryos, regardless of stage of treatment, to form blastocysts, treatment at the eight to sixteen cell stage and at the morula stage prevents blastocyst differentiation (present work and others)[3]. A higher drug concentration (0·1 μg/ml.), which inhibits cell division, severely inhibits RNA synthesis at all stages (Fig. 1).

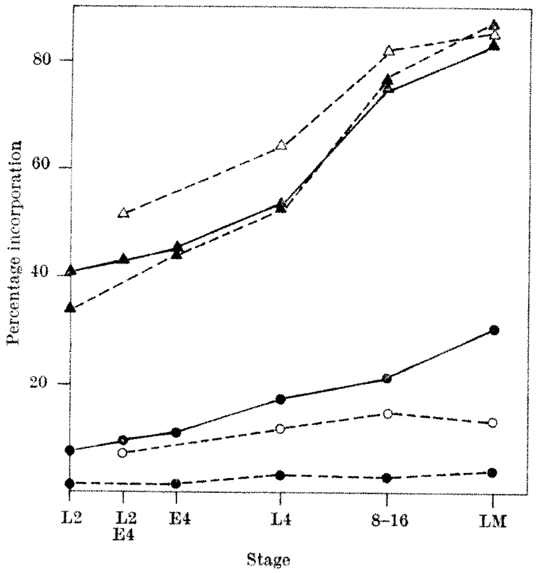

Fig. 1. Effects of actinomycin D on the rates of RNA and protein synthesis in cleavage stage mouse embryos. ^{14}C-leucine: ▲—▲, control; △---△, +0·0008 μg/ml. actinomycin D; ▲---▲, +0·1 μg/ml. actinomycin D. ^{3}H-5-uridine: ●—●, control; ○---○, +0·0008 μg/ml. actinomycin D; ●---●, +0·1 μg/ml. actinomycin D.

When rates of protein synthesis in mouse embryos are measured (controls, Fig. 1), it can be seen that 41 per cent of the ^{14}C-leucine which enters the two cell stage embryos is incorporated into PCA precipitable material during a 3 h treatment. This level of incorporation increases only slightly through the four cell stage. Between the L4 and eight to sixteen cell stages there is a major increase in the rate of protein synthesis (23 per cent higher than the rate at the L4 stage). This increase coincides with a great increase in the numbers of cytoplasmic polyribosomes noted in ultrastructural studies[10,12], and is in agreement with autoradiographic data[2]. The rate of protein synthesis increases to 83 per cent incorporation at the morula stage. These rates of protein synthesis are not altered during the exposure to actinomycin D (either 0·0008 μg/ml. or 0·1 μg/ml., Fig. 1), except for a slight reduction at the two cell stage (0·1 μg/ml.) and stimulation at the two cell and four cell stages (0·0008 μg/ml.). Actinomycin treatment of 0·1 μg/ml., which almost completely blocks RNA synthesis at each stage, does not reduce the rate of protein synthesis (Fig. 1).

Cycloheximide (0·5 μg/ml.) treatment decreases the rate of protein synthesis by at least 30 per cent at all stages (Fig. 2), but does not interfere with development. (Regardless of the cleavage stage at which treatment is applied, reincubated embryos continue to form blastocysts which differentiate normally.) The reduction in the rate of protein synthesis (absolute decrease in per-

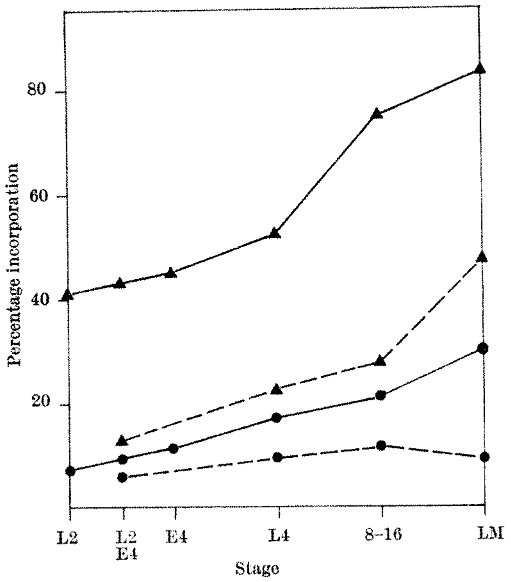

Fig. 2. Effects of cycloheximide (0·5 μg/ml.) on the rates of RNA and protein synthesis in cleavage stage mouse embryos. Embryos were incubated for 3 h at each stage in either 6 μCi/ml. ^{3}H-5-uridine (●) or 0·6 μCi/ml. ^{14}C-leucine (▲) in the presence (- - -) or absence (———) of cycloheximide.

centage incorporation) is approximately the same at each stage, except for a slightly greater inhibition at the eight to sixteen cell stage (Fig. 2). In addition to this effect on protein synthesis, cycloheximide reduces the rate of RNA synthesis, leucine uptake and, to a lesser extent, uridine uptake (Figs. 2 and 3). In each of these cases, the reductions are greater at the morula stage than at the earlier stages.

More detailed information concerning the effects of cycloheximide on RNA synthesis was obtained through sucrose density gradient analysis of drug-treated, ^{3}H-5-uridine labelled, morula stage embryos. Fig. 4 shows that the two major species of rRNA sediment at the same relative positions in both control and experimental gradient analyses. A quantitative analysis of the relative amount of 30–32S rRNA and 18S rRNA, in comparison with the total amount of new RNA synthesis (determined by perchloric acid (PCA) extraction), shows that although the cycloheximide treatment causes an 11 per cent reduction (15 per cent to 4·1 per cent) in rRNA synthesis, there is a reduction of RNA synthesis (PCA extraction) of 21 per cent. This latter reduction cannot be accounted for by the 11 per cent decrease in the rate of rRNA synthesis. Thus in cleavage stage mouse embryos, cycloheximide affects RNA synthesis in general, and is not specific for rRNA as opposed to reports on other systems[13].

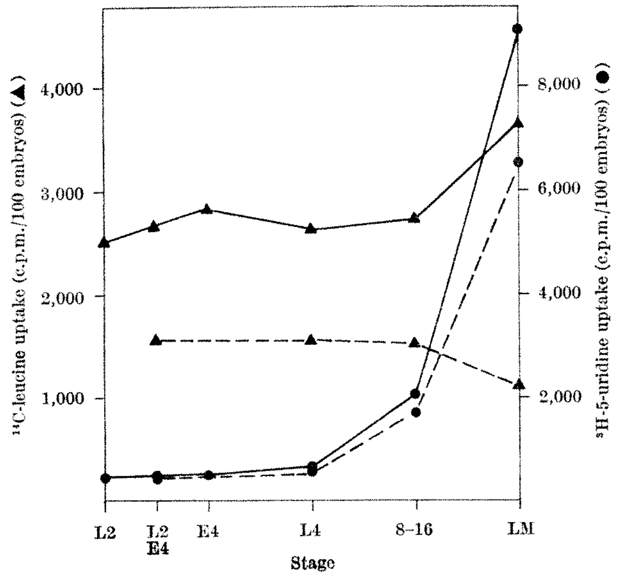

Fig. 3. Effects of cycloheximide (0·5 μg/ml.) on uptake of ^{3}H-5-uridine and ^{14}C-leucine by cleavage stage mouse embryos. The points on the graph represent the total uptake of precursors from the experiments shown in Fig. 2. The symbols are the same as those in Fig. 2.

	Percentage 30–32S rRNA	Percentage 18S rRNA	Total PCA extracted RNA (percentage incorporation)
Control (▲)	10	5	30
Cycloheximide (△)	3	1	10

Fig. 4. Inhibition of morula stage RNA synthesis by cycloheximide (0·5 μg/ml., 3 h). Sucrose density gradient analysis. Techniques for labelling, collecting and storing the embryos are the same as those described in the text. 25S, 18S (wheat germ rRNA, Calbiochem) and 4S (stripped calf liver sRNA, General Biochemicals) were used for the absorbance reference peaks (●). Thawed embryos were lysed in 0·5 ml., 0·01 M Tris-HCl (pH 7·4), 1 per cent sodium dodecyl sulphate, 100 μg/ml. polyvinyl sulphate. The lysate was placed on top of a 16·5 ml., 5–20 per cent sucrose gradient (prepared in 0·01 M sodium acetate, pH 5·0, 0·1 M NaCl, 0·1 mM EDTA) and the tubes were centrifuged at 24,000 r.p.m. for 18 h, 20° C, in a Spinco L2-65 ultracentrifuge (SW 25·3 rotor). Nine drop fractions were collected from the bottom of the gradient, the absorbance at 260 nm recorded for each fraction, and radioactivity assayed in a Packard 'Tri-Carb' liquid scintillation counter. The amount of radioactivity under each rRNA peak is summated and expressed as a percentage of the total uptake of ^{3}H-5-uridine by the embryos. The radioactivity at the top of the gradients is largely acid-soluble material. The data for total PCA extracted RNA, expressed as percentage incorporation, are derived from the experiments shown in Fig. 2.

In summary, the lower concentration of actinomycin D neither blocks cell division nor blastocyst differentiation when applied at the two cell or four cell stages. This is reasonable when one considers that rRNA synthesis is either non-detectable or at relatively low levels at these early stages[8,9,14], and may not be needed for early cleavage stage protein synthesis. The greater inhibition of RNA synthesis in the later stages probably reflects the normally increased rates of rRNA synthesis at these stages[8,9]. The inhibition of rRNA synthesis may be responsible for the blockage of blastocyst differentiation in embryos which were treated at the eight cell and morula stages.

The use of 0·1 μg/ml. of actinomycin D shows that concurrent RNA synthesis is not necessary for protein synthesis during mouse cleavage. This suggests that the messenger, transfer and ribosomal RNAs which are required for protein synthesis are stable for at least 3 h at each stage. This same concentration of actinomycin D, however, blocks cell division. Although this blockage may be the result of the almost total inhibition of RNA synthesis, high concentrations of the drug are known to damage chromatin material[4,15]. This effect could also be responsible for the cessation of cell division.

The cycloheximide experiments show that normal rates of protein synthesis are necessary for the maintenance of the normal rates of RNA synthesis and leucine and uridine uptake. The time between the inhibition of protein synthesis and the inhibition of transport and RNA synthesis may reflect the size of the available pool of proteins required for these processes. In the present instance, the rates of RNA synthesis and the transport of amino-acids and nucleosides are reduced in less than 3 h. Thus in normal conditions the required proteins must be newly synthesized within a 3 h period. The greater inhibition of both RNA synthesis and transport of precursors at the later cleavage stages may be caused by an increasing demand for certain proteins which are involved in these activities[16-20]. It is likely that newly synthesized ribosomal proteins are among those proteins required at the later cleavage stages, for these stages are characterized by large increases in the production of rRNA[8,9], the appearance of many cytoplasmic polyribosomes[10] and the incorporation of ^{3}H-leucine into the nucleolus[2]. Further studies should clarify some of the interrelationships between RNA and protein synthesis in cleaving mouse embryos.

This work was supported by a research grant and a training grant from the US National Institutes of Health.

Non-Darwinian Evolution: A Critique

by

ROLLIN C. RICHMOND

The Rockefeller University,
New York, NY 10021

The view that most evolutionary changes in DNA need not be attributed to natural selection rests on several lines of evidence. This article argues that the evidence leads more simply to a neo-Darwinian interpretation.

INVESTIGATING the genetic structure of natural populations of organisms, including man, has long been a goal of population geneticists. Understanding the genetic architecture of populations might make it possible to evaluate mathematical theories that predict the rates of frequency changes of genes within populations. Furthermore, such information might give at least a partial answer to a question that has interested man since the beginning of his interest in the biological world: what is the difference between species?

While biologists are a long way from such an achievement, molecular investigations of a number of proteins have begun to add to the data amassed by population geneticists during the past few decades[1]. The new molecular data[2-4] have brought into sharp focus the discrepancies between the predicted amounts of genetic variability, and postulated evolutionary rates on the one hand, and observed degrees of genetic variability on the other. Haldane[5], and later Kimura[6] and others, have argued that the substitution of one gene for another in a natural population places a burden or load on the population, because for the replacement to occur one individual must replace another (a genetic death, in Muller's terminology[7]) or leave relatively more progeny in a population of assumed constant size (substitutional load, in Kimura's terminology).

Data derived from studies of isozyme variability in *Drosophila*[2,3,8] show that natural populations of these species have polymorphisms at about 30 per cent of their structural gene loci, and an average individual can be expected to be heterozygous for some 12 per cent of his structural loci. Harris[9] and his colleagues have found similar degrees of variability after examining twelve enzyme systems present in human blood.

These data are incompatible with the model of evolutionary change involving the concepts of genetic death and substitutional load. If the observed genetic variability is maintained by natural selection, favouring individuals heterozygous for a number of loci, the maximum reproductive potential of a population would be reduced to an absurdly low value[2], even if one assumes only a 5 per cent loss in fitness of homozygous or nearly homozygous individuals. The model, of course, assumes that selection acts on each locus independently. It is clear that most natural populations are realizing a much higher reproductive potential than the theory would allow.

Several authors[10-14] have criticized these conclusions and pointed out that selection acts on whole organisms and populations of organisms rather than specific loci. Integrating this premise into Haldane's model makes it possible to account for the high amounts of genetic variability observed, and retain heterotic balance as a primary mechanism for maintaining the variability.

Evidence is rapidly accumulating on the primary structure of proteins in various classes of organisms. The *Atlas of Protein Sequence and Structure*[4] provides a valuable compilation of sequence data on many proteins and facilitates comparative studies of the evolution of proteins. As a result several authors have proposed that a new paradigm needs to be established to understand the observed variation in the presumed phylogenetic sequences of a number of proteins[15-17].

Their basic postulate is that most evolutionary changes in DNA need not be attributed to the action of natural selection. They claim that we know enough of the chemistry and physics of organic molecules to recognize parts of these structures that can be varied without altering their functional significance. In other words, some changes in DNA are adaptively neutral or undetectable by natural selection because the altered proteins or different tRNAs encoded have identical functions in the organism. Changes in DNA which are presumed to result in no selective advantage or disadvantage are the result of what has been termed "non-Darwinian" evolution[15].

Several lines of evidence have been brought together to uphold this conclusion. I intend to show here that the evidence can be interpreted more simply and validly within the framework of the neo-Darwinian or synthetic theory of evolution.

Synonymous Mutants

Because the genetic code is degenerate, some base pair changes in DNA do not result in the substitution of a different amino-acid into the encoded protein. This class of mutants, termed synonymous, has been cited as a prime example of neutral alterations in DNA[15,17]. Some recent findings make this idea questionable.

Several tRNAs are known to exist for some of the amino-acids, while the degeneracy of codons for other amino-acids is interpreted to mean that tRNAs are capable of recognizing several codons[18]. Suppose, for example, that the third position of a leucine codon has mutated from A to C. While still coding for leucine, another tRNA must be used in the synthesis of the encoded protein. For this synonymous mutation to be truly neutral, the various tRNAs bearing leucine molecules must be present within the cell, in equal supply, and the synthesis of each tRNA species must require approximately equal amounts of energy output by the cell. Caskey *et al.*[18], and others, have demonstrated that the first two of these three conditions do not hold at least for *E. coli*, yeast and mammalian liver (guinea-pig). Even if the conditions were met, one could not ignore the fact that regulatory molecules are known to bind to DNA[19] and alterations of the nucleotide sequences might affect the binding and subsequent function of these molecules. Such interference with a basic cellular mechanism can hardly result in a neutral effect for the organism.

The *mut-T* Gene of *E. coli*

Several authors[15,17] who postulate neutrality of many or most mutants have pointed out that a gene (*mut-T*) in *E. coli* has the effect of mediating AT to CG transversions within the bacterial DNA. Cox and Yanofsky[20] have investigated the effects of this gene continued for 1,200–1,600 generations on the GC content of *E. coli*. They found an increase of 0·4–0·7 per cent in the GC content, which corresponds well with that predicted from a knowledge of the mutation rates of known markers in strains bearing the *mut-T* gene. The authors note that the increased GC strains have apparently normal viability even though they are being grown on minimal medium.

These observations may be equally well or better interpreted on the basis of selection for those AT to CG transversions which are not deleterious to their carriers. A number of difficulties are, however, apparent in such an interpretation. First, the actual numbers of mutations accumulated over the course of the experiment cannot be estimated precisely, because the molecular weight of *E. coli* DNA is not exactly known. Second, as Cox and Yanofsky[20] point out, the reversion rate of *mut-T* mediated AT to CG transversion has not been taken into account. The presence of several chromosomes in an actively growing bacterial cell complicates the issue even further and would seem to make precise calculations difficult. While the increased GC strains are able to grow apparently normally, no attempt has been made to assess their ability to compete with strains that have a normal GC content and lack the *mut-T* gene. In conditions of competition, the frequency of the *mut-T* would give an indication of the fitness of the mutants induced in those bacteria carrying the gene. The adaptive value of the induced mutants could only be tested in a competitive situation.

Constancy of the Rate of Molecular Evolution

The initial observation that the rate of amino-acid substitution in cytochrome c was apparently linear with respect to time, and therefore apparently a result of some internal cellular process rather than representing the effects of a varying selection pressure, has been interpreted as evidence for the existence of neutral mutants[17,21]. The validity of this conclusion depends on estimates from palaeontological data of the times of divergence of various faunal groups. Although such data are available, they are subject to large errors and the conclusions based on them should not be taken as established[22]. Indeed, according to Simpson[23], the hypothesis of a constant rate of amino-acid substitution is not supported when the available data are plotted against the best estimates for the times of divergence of the species in question. Further, a comparison of the estimated number of amino-acid substitutions per codon for nine mammalian proteins (ref. 15, Table 1) reveals a wide range in the average number of substitutions. This would not be expected if a linear and constant rate of amino-acid substitution was the case.

Distribution of Changes in Proteins

A number of proteins contain amino-acid sites which have not apparently changed in phylogeny. These sites are assumed to be essential for the basic function of the molecule. Rare variants of these "invariant" sites which do occur in haemoglobin, for example, result in drastic alterations in the structure and function of the molecules[24]. Such "genetic diseases" are undoubtedly subject to severe selection. Many of the remaining sites in the haemoglobins and other proteins have changed in the course of evolution. It has been postulated[15] "that there is very little restriction on the type of amino-acid that can be accommodated at most variable sites". This conclusion is supported by the finding that the number of amino-acid changes per site agrees well with what is predicted if one assumes a Poisson distribution for the number of observed substitutions per site. Other interpretations of this finding are, however, possible.

Data compiled and analysed by Dayhoff[4] and others on the patterns of change in amino-acid substitutions in all the completely sequenced proteins show anything but a random pattern of substitution. Indeed, in a number of cases, the amino-acid most often substituted for the original amino-acid requires that more than one base of the original codon be altered. Such a pattern could be present only if natural selection has influenced the acceptance of amino-acid alterations.

For a substituted amino-acid to be of neutral selective value compared with the original amino-acid, a rather specific set of conditions must be met. The physiological functioning of the molecule must not be disturbed. Demonstration of apparent functional identity *in vitro* is not conclusive. The normal adult haemoglobin molecules of the gorilla and man bind oxygen with equal efficiency *in vitro*. Gorilla haemoglobin differs from human haemoglobin at two sites, one in the α chain, the other in the β chain[4]. Yet no man has ever been found with gorilla haemoglobin and at present no gorilla has been found with human haemoglobin (ref. 24, and personal communication from T. Dobzhansky).

Even if a substituted amino-acid were truly neutral in a functional sense, it is highly unlikely that factors involved in the synthesis of the protein would render the substitution neutral in the broader sense of the organism's integrated functioning. The substituted amino-acid must be present within the cell in equivalent quantity compared with the original amino-acid and, indeed, its synthesis or derivation from other molecules and transport into the cell require an equivalent amount of energy output. Amino-acids are not present within cells in equivalent quantities[25] and different mammalian organs show differences in concentration[26]. Investigation of the amino-acids present in human plasma shows a wide range of concentrations[27]. Further, the mechanisms for transport of amino-acids into cells further complicate the problem. The amino-acids vary in their ability to be transported across mucosal membranes and can be arranged into "transport families"[28]. Competition as well as facilitation of transport exist within and between such families.

Because mutations occur randomly, one would expect to find a Poisson distribution for any given set of genes or codons if the past history of mutation for each gene can be ascertained. The interesting and significant fact is not that the codons embodying the messages for globins, cytochromes c and immunoglobins G have mutated in a seemingly random fashion, but that the mutations that have been selected fall into non-random classes the composition of which can be understood from the physical and chemical properties of amino-acids.

Rates of Change of DNA and Protein

Measurement of the relative similarity in the nucleotide sequences of two sets of DNA by *in vitro* hybridization techniques has made it possible to estimate the divergence of two species based on DNA changes alone. If estimates of evolutionary rates are made from percentage changes in DNA sequences, values are obtained that are approximately one order of magnitude greater than those from estimates obtained from the rates of amino-acid substitutions in proteins[15]. This difference is interpreted as evidence for the presence of synonymous mutants which are neutral alterations in the DNA sequence. Considering the number of assumptions each estimate needs, the agreement would seem to be remarkably good.

But several other difficulties suggest themselves. Somewhat less than 50 per cent of the DNA of mammals studied occurs in the so-called repetitive sequences[29]. Further, parts of the genome are translated but never appear as cytoplasmic RNAs or structural protein. As Wallace[30], Stebbins[31] and, later, Britten and Davidson[29] have pointed out, much of the difference between higher species and faunal groups may reside in the dissimilarities of regulating mechanisms. Such differences are not represented in structural proteins from which estimates of evolutionary rates have been made.

Amino-acid Composition of Proteins

The hypothesis has been proposed that the amino-acid composition of protein is largely determined by the structure of the genetic code[15,32]. In other words, those amino-acids with the greatest number of codons (serine, leucine, arginine) are expected to be most frequent in proteins. If a plot of observed and expected amino-acid frequencies is made (expected frequencies are corrected for nucleotide frequencies in mRNA and for nonsense codons) for a large number of proteins, the correlation between predicted and observed values is very good (ref. 15, Fig. 1). This finding is interpreted as further evidence for the hypothesis " . . . that the average amino-acid composition of proteins reflects, more or less passively, the genetic code"[15]. The converse hypothesis, that natural selection influences the amino-acid composition of proteins, allegedly leads to the prediction that no relationship should exist between amino-acid frequencies and the structure of the code. Both of these expectations ignore the fact that the genetic code itself is a product of the evolutionary process.

A closer examination of the frequencies of occurrence of amino-acids yields the conclusion that the distribution is not simply linear, as has been proposed. Mackay[33] has shown that the amino-acids can be put into three natural groups based on their observed frequencies.

Dayhoff[4] has given the relative mutabilities of the amino-acids for all sequenced proteins. The relative mutability is a measure of the probability that an amino-acid at a given site in a protein will change in some small time interval. If most amino-acid residues in protein are not subject to selection, the relative mutabilities should also correlate with the number of codons for each amino-acid in the code. No correlation exists between relative mutabilities and the number of codons for each amino-acid.

The mechanisms of protein synthesis and the manner in which stored information is translated into protein structure are remarkably complex. Indeed, the very complexity of the code itself argues for a long history of evolutionary change which has produced the efficient and accurate system of modern organisms[34]. The patterns of degeneracy within the code have been explained as a mechanism to reduce the effects of mutation on protein structure[35]. Woese[34] and Crick[36] have argued that the degeneracy patterns are the result of the gradual evolution of a primitive system using a few amino-acids, each probably coded for by a larger number of codons than the maximum in the present code. New amino-acids could be incorporated into the evolving system if their accidental presence in a protein conferred a selective advantage on the primitive cell or replicating system. As the system evolved accuracy, protein structure became more precise until the insertion of any new amino-acid into the system disrupted the structure of too many proteins ever to confer a selective advantage. Only in this sense does the amino-acid composition of proteins reflect, as King and Jukes[15] and Kimura[6] have suggested, the genetic code. But the code has evolved as a response to the effects of selection on the molecule the synthesis of which it directed. The observed amino-acid composition of proteins is then a result of the effects of selection.

Allozyme Variation and Natural Selection

Zone electrophoresis followed by selective staining for enzyme or non-specific structural protein allows for the detection of functionally similar but physically or chemically different enzymes. Such variants, termed isozymes or allozymes[37], are similar in kind if not identical to those resulting from amino-acid substitutions in such proteins as haemoglobin and cytochromes c. Population genetic studies of all allozymes provide evidence that natural selection affects the frequencies of genes controlling allozyme structure.

Kojima and Yarbrough[38] demonstrated that two alleles at an esterase locus in *Drosophila melanogaster* reached a stable equilibrium in population conditions. Analysis of viability differences associated with changes in the frequencies of the alleles revealed a gene frequency-dependent selection system. At the point of genic equilibrium, no selective difference in viability was detected among the three possible genotypes. At frequencies other than the equilibrium value there were viability differences.

Dobzhansky[1] has theorized that genes contained within chromosome inversions in *Drosophila pseudoobscura* have been selected to produce phenotypes of high fitness when in heterozygous combinations with other inversions from the same population. Analysis of allozyme variants within the inversions of *D. pseudoobscura* has demonstrated that the genic content of third chromosome arrangements is differentiated to allow for the production of maximum amounts of heterozygosity[39]. Moreover, a given inversion usually contains a particular allele throughout the distribution of the species. Because occasional mutant gene arrangements occur, there is ample possibility for the effects of chance variation to substitute neutral alleles into a gene arrangement. This has not occurred. Prakash and Lewontin[39] estimate that the gene arrangements found within *D. pseudoobscura* are approximately one million years old. Natural selection has acted to maintain the genetic differentiation among these inversions for at least as long as this.

Demonstration of a cline in gene frequencies provides indirect evidence for the action of natural selection at the locus in question. O'Brien and MacIntyre[8] have analysed allozyme variability in natural populations of *D. melanogaster* and *simulans*. They report evidence for a cline in the gene frequencies for allozymes of alkaline phosphatase and 6-phosphogluconate dehydrogenase. A similar finding has been reported for an esterase locus in *D. pseudoobscura*[37]. Burns and Johnson (ref. 40, and personal communication) have studied esterase allozyme variation in natural populations of the sulphur butterfly *Colias eurytheme*. Clinal variation in the frequencies of several of the many alleles present at one esterase locus in this species has been demonstrated.

Perhaps the most convincing demonstration of the action of natural selection in maintaining clinal variation has been provided in a study by Koehn[41] of the freshwater fish, *Catostomes clarkii*. The two alleles at a serum esterase locus show clinal variation correlated with latitude. Koehn has been able to relate the variation to differences in temperature by assaying the activity of the esterase allozyme associated with each of the three genotypes. The two homozygous genotypes produce esterases which have maximum activity at opposite ends of the temperature range encountered by the species. The serum esterase produced by the heterozygous genotype has maximum activity at intermediate temperature. Koehn has identified not only the primary selective force acting on the three allozymes but also the physiological difference which allows selection to act.

The mechanisms of the action of natural selection are often misunderstood, and indeed there remains much to be elucidated about its effects. Dobzhansky[42], Simpson[23] and others have pointed out that natural selection does not act on separate genes or traits but on whole genotypes and phenotypes. Selection for single genes must be a rare phenomenon; even in cases such as industrial melanism studied by Kettlewell[43] and others, the pleiotropic effects of the gene in question and the genetic background within which the gene must act all influence the outcome of the selective process. Molecular data of the types discussed here may add an invaluable dimension to our understanding of the evolutionary process, but such information should be considered in the light of what is already understood of the nature of evolution.

Some of the ideas and approaches presented here resulted from discussions with T. Dobzhansky and Francisco J. Ayala, who also criticized the manuscript. My work was supported by the US National Institutes of Health and the US Atomic Energy Commission.

Are they entrapped solar wind particles, meteoritic or cometary contributions, remnants of a primordial atmosphere or products of the degassing of the Moon ?

THE Apollo 11 lunar samples contain traces of carbon compounds[1–8]. A number of the investigators regard some of the low molecular weight carbon compounds, such as CH_4, CO and CO_2, to be indigenous to the Moon. It is difficult to explain the origin of CH_4, CO and CO_2 by terrestrial contaminations. If the lunar fines and rocks had been contaminated by these gases, other gaseous products—such as those common in the environments to which the samples were exposed on Earth (N_2, O_2 and so on)—should also be present in significant quantities. These have not been found, however. Contaminations from exhaust gases of the lunar descent module engine are more likely, yet the samples are apparently relatively free from these contaminants[9]. Furthermore, particles of the lunar fines (10086) and the rocks (10002, 54) contain small cavities[1], some of which seem to be filled with seemingly undisturbed fluid substances.

Higher molecular weight compounds were also detected in the lunar samples. A few ninhydrin positive substances, possibly amino-acids[1,8], were obtained. Lunar fines (32·66 g) were extracted with water in a Soxhlet apparatus.

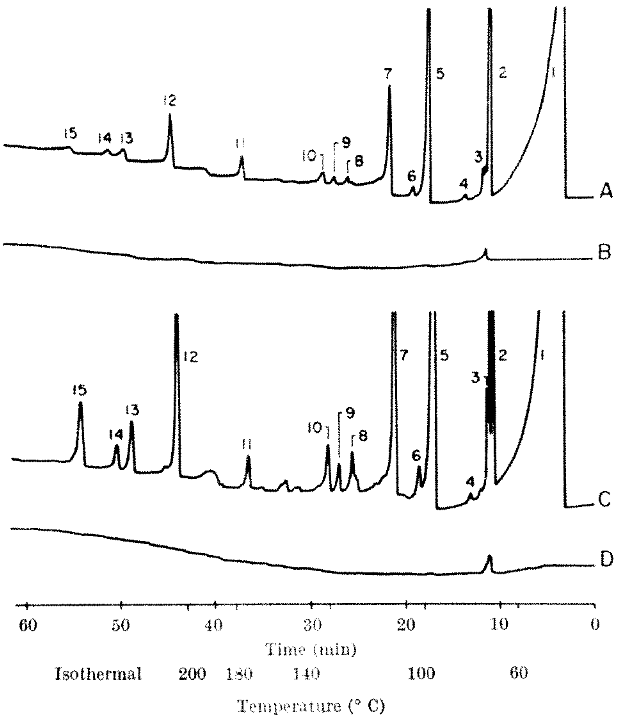

Fig. 1. Gas chromatograms of the pyrolysis products of, *A*, untreated lunar fines (sample 10086) and lunar fines, *C*, treated with benzene–methanol (4 : 1) which was used to remove soluble organic substances such as common contaminations; traces of solvent were removed by heating the solvent extracted sample in a vacuum oven at 134° C for 6 h at 35 mm Hg pressure. Peak 1, H_2 and CH_4; 2, CO_2, C_2H_4 and C_2H_6; 3, C_5H_8; 4, C_5H_{10}; 5, benzene; 6, thiophene; 7, toluene; 8, 9, *m* and *o*-xylenes; 10, styrene; 11, indene; 12, naphthalene; 13, 14, 2 and 1-methyl naphthalenes; 15, diphenyl. Some of the smaller peaks were also identified and are referred to in the text. Curves *B* and *D*: blank procedure runs for *A* and *C*, respectively. The two small peaks shown on curves *B* and *D* are reproducible instrumental background.

The individual components of the extract were separated by a high resolution ion exchange column[10] and analysed at the 5700 Å wavelength absorption of the ninhydrin positive species. What seems to be glycine, alanine, ethanolamine and urea were present in 32, 36, 22 and 65 p.p.b. quantities, respectively[1]. Utmost care was exercised to exclude laboratory contaminations and, in fact, procedure blanks showed a different amino-acid pattern (at lower concentrations) than the lunar fines. It should be noted that glycine and alanine are amino-acids most commonly synthesized in simulated primitive Earth (abiological) environments (Miller–Urey and related syntheses, refs. 11–13). A sample of the terrestrial rock, dunite, subjected by NASA in an initial vacuum to the exhaust of the lunar descent module engine, did not exhibit the same amino-acid distribution as the lunar samples; nor did the biological controls[1].

Pyrolysis experiments of both lunar fines and the interior of a lunar breccia showed CH_4, C_2–C_5 hydrocarbons, CO_2, as well as aromatic compounds: benzene, toluene, *o*, *m* and *p*-xylenes, ethylbenzene, styrene, indene, naphthalene, biphenyl, thiophene and several methyl substituted isomers. A peak of $m/e = 28$ in the low resolution mass spectra may be CO (ref. 1). CO has been described as the major component by high resolution mass spectrometry[2]. It has also been reported[2] that CO was the major component liberated when the fines were dissolved with HF. Straight-chain alkanes of high molecular weight have been found by mass spectrometry in one extract of lunar fines[1], but there is some reason to believe that they may be contaminations.

Pyrolysis Experiments

The pyrolysis products were obtained in the Organic Geochemistry Laboratory of the University of Arizona using a modified Hamilton pyrolysis unit, consisting of an externally heated fused quartz tube (43 cm × 4 mm internal diameter) connected through a heated transfer line and a liquid N_2 trap to a Perkin–Elmer model 226 gas chromatograph, containing a 50 feet × 0·02 inch internal diameter polyphenyl ether capillary column and by hydrogen flame detector. The column was first run isothermally at 60° C and also after 200° C. The gas chromatograph was in turn connected through a Watson–Biemann molecular separator to a Hitachi 'RMU-6E' single focusing mass spectrometer. Samples of fines, 623·4 mg and 717·2 mg, untreated and sonically extracted with benzene–methanol (4 : 1), respectively, were pyrolysed for 7·5 min in a stream of He (3–5 ml./min). The solvent extracted sample (717·2 mg) had been heated for 6 h at 134° C in a vacuum oven at 35 mm Hg pressure before pyrolysis to remove traces of the benzene and methanol. The pyrolysis products condensable at − 196° C temperature were collected in the liquid N_2 trap which was next heated rapidly to 250°–300° C with an adjustable oven to release the trapped products instantaneously into the gas chromatograph.

Fig. 1 illustrates the pyrolysis curves of the untreated and solvent extracted fines together with the corresponding blanks. The two curves show close agreement, suggesting that the pyrolysis products are not common terrestrial contaminations which would have been removed by solvent extraction. At least some of the aromatic hydrocarbon products could have been synthesized by pyrolysis. It has been reported[14] that basically the same aromatic hydrocarbons are obtained when methane is heated at higher temperatures (1,000° C) over silica gel.

Examination by Microscopy at Elevated Temperatures

Lunar fines were examined in Permount preparations with a Leitz 'Ortholux' microscope before and after pyrolysis at 700° C. In addition, lunar fines on sapphire disks were examined with a Leitz water cooled heating stage, model 1350, mounted on a Leitz 'Ortholux' microscope, during continuous heating in air from room temperature to 1,250° C.

The untreated lunar fines showed mineral debris and relatively few glass spheres and dumbbell shaped particles; this was also noted by several other investigators. A number of the glass beads seem to contain cavities, presumably consisting of enclosed matter. A few of the glass beads which were pyrolysed at 700° C had openings connected with hollow interiors; others still showed unopened bubble-like enclosures.

Heating of the lunar fines while the temperature was gradually raised led to the disappearance of transparent central spots in glass beads around 800°–850° C. These spots may represent optical effects or hollow interiors in the beads. Their disappearance suggests chemical changes in the glassy material or in the encapsulated substances. On further heating to about 1,250° C the irregular particles melted and the resultant silicate melt showed slight bubbling. Glass beads generally did not display sharp melting points, and at least one particle was observed at approximately 1,150° C to spread apart instantaneously in an irregular, radiating shape as if it had been disrupted by increasing internal pressure; this disruption seems to be rare. Our observations raise the possibility that some of the lunar fine particles contain gaseous or low molecular weight components in enclosures.

Morphological Features revealed by Scanning Electron Microscopy

Both the lunar fines and the lunar rock chip (breccia, both the outside and the freshly broken inside surfaces) were examined with a 'Stereoscan Mark II' electron microscope (Cambridge Instruments). In a special clean room, the fines were placed on precleaned sample pedestals with a drop of absolute ethanol which was then allowed to evaporate. The rock chip was secured to the pedestal with a double adhesive tape. The samples were placed in a bell-jar chamber which was next evacuated and the pedestals were rotated at 120 r.p.m. under a grid of Au–Pd (90 : 10) alloy wires heated to incandescence. An approximately 500 Å thick layer of Au–Pd, containing no coating artefacts such as granular textures, was deposited on the surfaces of the samples.

Glass beads were either spherical, nearly spherical or dumbbell shaped (Figs. 2*a*, *c*, *d*). They exhibited various surface features, the most prominent of which was the small, irregular shaped particles partially embedded in the bead surfaces (Figs. 2*a*, *b*, *c*, *d*). Some broken glass beads had hollow interiors[1]. The fine particles usually showed "felted" surfaces (Figs. 2*a*, *b*, *d*) whereas broken surfaces revealing the interiors of particles or of rocks did not manifest this "felted" effect (Fig. 3*d*). Broken interior parts of the rock (Figs. 3*b*, *d*) had an abundance of submicroscopic sized spherical cavities. The interiors

The horizontal white lines represent 5 μm.

of impact craters (Fig. 3*a*) were lined with a thin fused crust which resembled a frozen, once frothy and boiling melt with cavities behind the shells of the bubbles (Figs. 3*a*, *c*). Freshly broken surfaces of the breccia demonstrated that glass beads also occurred embedded in the fine grained matrix.

Possible Origin(s) of Carbon Compounds on the Moon

The nature and quantity of the carbon compounds as well as the morphology of the lunar fines and rocks may help to elucidate the origin of the carbonaceous substances on the Moon. In this study CH_4, CO_2, CO and the aromatic compounds were primarily considered. These compounds were found and independently confirmed by most investigators[1-4,7].

(1) The accumulation of carbon and hydrogen from the solar wind is one possible explanation for the origin of the carbon compounds. An experiment on Tranquillity Base measured the influx of solar wind He, the results showed $6{\cdot}3 \pm 1{\cdot}2 \times 10^6$ He atoms/cm²/s (ref. 15). Using the solar proportions of the elements of Suess and Urey[16] the influx of carbon on the Moon during geologic time ($4{\cdot}6 \times 10^9$ yr) is 0·011125 g/cm². The solar wind derived carbon content of the lunar surface was estimated by Moore *et al.*[17] to approximate the experimentally determined values of carbon. These estimates were based on calculations of the relative retention of the rare gases on lunar materials which the authors pointed out is a major unknown

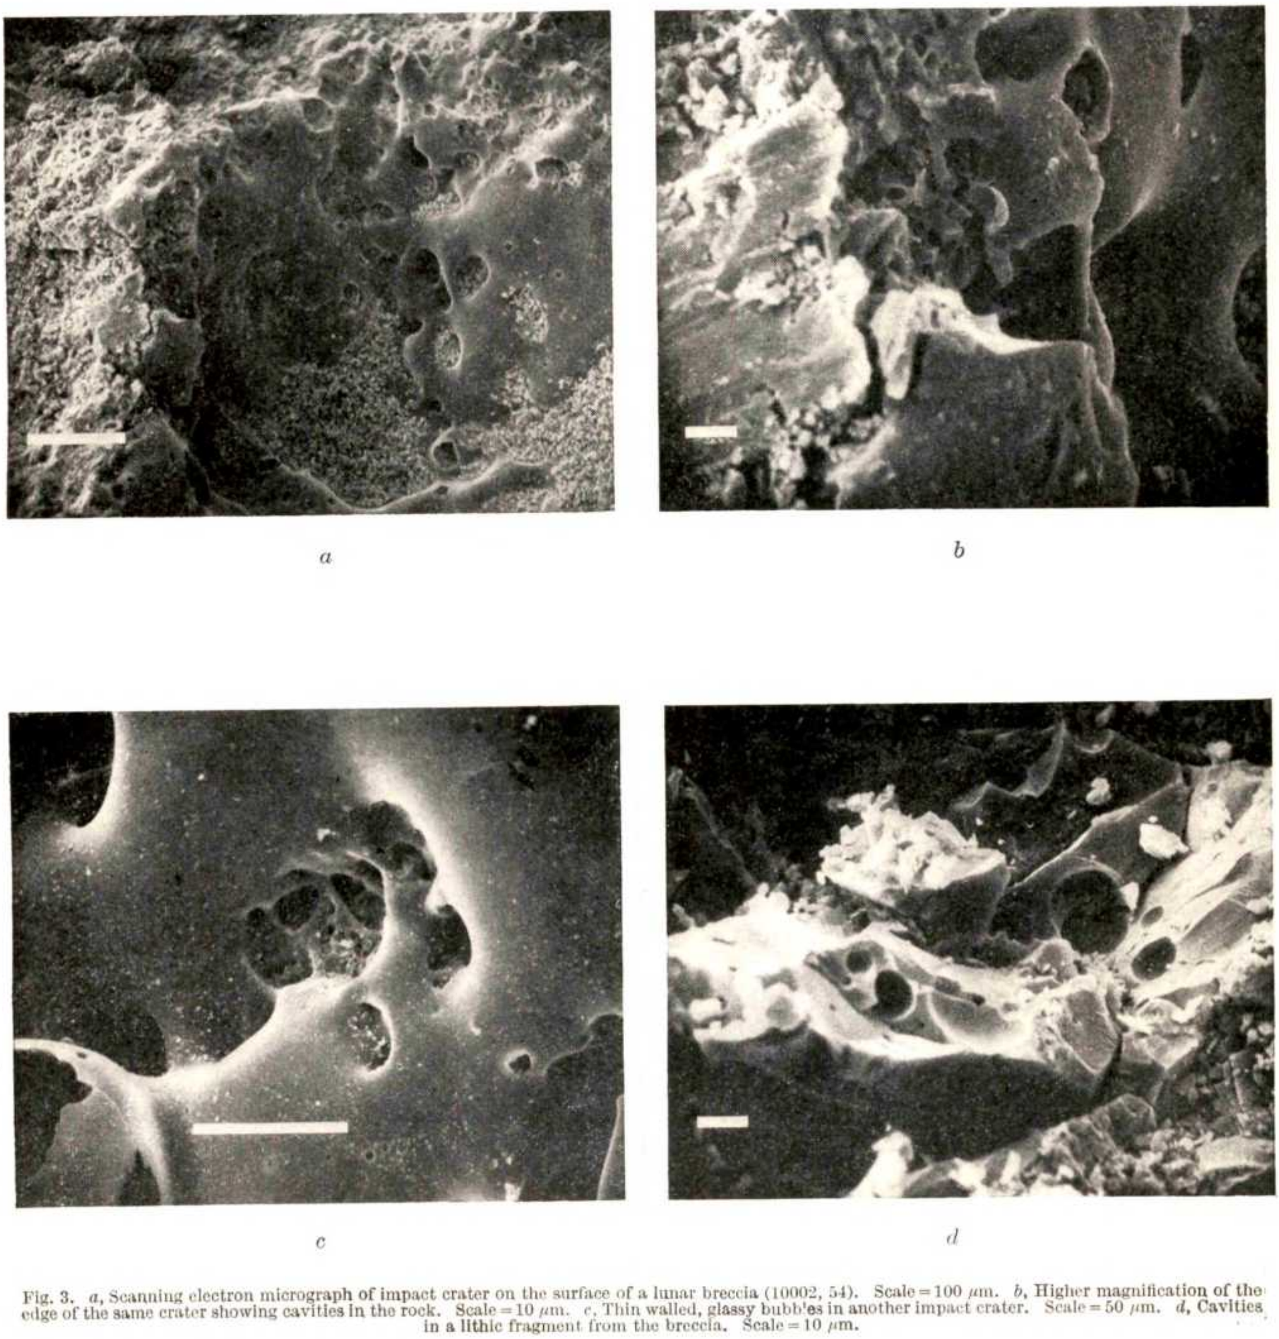

Fig. 3. *a*, Scanning electron micrograph of impact crater on the surface of a lunar breccia (10002, 54). Scale = 100 μm. *b*, Higher magnification of the edge of the same crater showing cavities in the rock. Scale = 10 μm. *c*, Thin walled, glassy bubbles in another impact crater. factor. Because carbon from the solar wind would penetrate only the uppermost layers of mineral matter and because the lunar fines on the lunar surface were repeatedly churned up and mixed, one could visualize an average carbon content in the top lunar surface of approximately 150–250 p.p.m. Yet it seems from the Apollo 12 measurements, according to preliminary data, that the carbon content increases with depth (personal communication from D. A. Flory); this makes it difficult to account for the carbon content from the solar wind alone. It could be argued that the solar wind carbon and hydrogen formed volatile carbon compounds that were more easily lost near the lunar surface than from deeper layers. Yet these very surface samples still contain significant but small (about 10–150 p.p.m.) quantities of CH_4, CO, CO_2, and so on, which should have been lost long ago if they were not securely entrapped in cavities and other suitable locations inside the rocks and in the glass beads. The cavities in the fine particles attest to a reasonably high vapour (or gas) concentration at early lunar times because these fines, with the cavities, seem to be[18] very old ($4{\cdot}5 \times 10^9$ yr). It is difficult to visualize how a high concentration of carbon could have already accumulated throughout a relatively thick lunar surface layer from the solar wind right at the beginning of lunar history. It therefore seems that the solar wind origin of the carbon content must await confirmation by further experimental data.

Accumulation from Meteorites, Comets and a Primordial Atmosphere

(2) The accumulation of carbon from carbonaceous meteorite and cometary impacts on the Moon is another possibility. Nothing is known, of course, about cometary carbon contribution to the surface of the Moon, but it has been estimated[19] that impacted carbonaceous meteorites account for not more than approximately 1·5–2 per cent of the lunar surface matter. Carbonaceous meteorites contain up to 7 per cent carbon compounds (in type I; in type III approximately 0·5 per cent). Using an average meteoritic carbon content of 2 per cent approximately 400 p.p.m. meteoritic carbon could be present in the fines and breccias. This again approximates the carbon content of the Apollo 11 samples. Certain organic components of carbonaceous meteorites, such as the higher molecular weight branched and cycloalkanes, are, however, missing from the lunar samples. Basically the same argument seems to hold true for the meteoritic carbon as for the solar wind carbon. Carbonaceous meteorites are relatively frequent arrivals on Earth in present times and their cosmic ray exposure ages are low. Is it possible that there was already enough meteoritic carbon present very early in lunar history to account for all the carbonaceous gases forming the cavities? The larger particles containing cavities—some of which could have formed at a later time from melts—would particularly be expected to show some morphological deformation if they were scattered, while still molten, through relatively dense carbonaceous vapours.

(3) It is also possible that the primitive Moon may have had an atmosphere. Ammonia, water[2,20] and methane, which would likely form such an atmosphere based on theoretical considerations, have been reported in trace quantities in the lunar samples. As noted previously, glass beads and dumbbells were once molten, which is demonstrated not only by their shapes but also by the numerous irregular mineral grains adhering to or partially embedded in their surfaces. Yet these particles, which were formed and splattered at an early stage when an atmosphere still would have been present, show no signs of the deformation in shape which molten particles, particularly the large ones, would have acquired from atmospheric friction during flight. In other words, they do not have aerodynamic shapes. Considering that the apparent impact hole and splash marks on the glass bead (shown on the bottom edge of Fig. 2c) were caused by a particle of diameter less than 0·1 of the diameter of the glass bead, the mass of the particle must have been less than 10^{-3} of the glass bead. The conclusion, and observations of the cratering effects of particles impacting from detonation and shaped charge studies, lead to a particle velocity of the order of 6–9 km/s. Velocities of this magnitude are not maintained by such small particles in a gaseous atmosphere of any appreciable density for any length of time, which argues strongly against a relatively dense atmosphere at the early times when the glass beads were formed.

Degassing from the Moon

(4) Finally, the possibility that the carbon compounds originate from the degassing of the Moon has to be considered. Carbon was a relatively common element in the solar nebula, so that the accreting primitive Moon must have included significant quantities of carbon. While part of the light elements would have been readily lost near the lunar surface, some must have been left behind incorporated in the melts that formed the crystalline rocks, glass beads and the breccias. This could explain the increasing carbon content with depth, the cavities and bubbles, and the lack of aerodynamic shapes of the glass beads. We suggest that the lunar carbon compounds may originate from the degassing of the Moon with possibly lesser contributions from solar wind and perhaps meteoritic sources.

We thank Mrs Alice Lumpkins, Judith Modzeleski, Sister Mary Ellen Murphy and Dr Maria Young from the University of Arizona; Mrs Reba Ward of the Naval Weapons Center, China Lake; Mrs Roberta De Fiore, Johanne C. Dickinson, Janet Greenquist, Drs Marjorie Lou and T. Timothy Myoda of the Alfred I. Du Pont Institute, Wilmington, for their assistance. One of us (B. N.) thanks Dr G. P. Kuiper of the University of Arizona for discussions on the origin of lunar carbon compounds. This investigation was supported by the US National Aeronautics and Space Administration with contributions from the Naval Weapons Center, China Lake, and the Alfred I. Du Pont Institute.

LETTERS TO THE EDITOR

GENERAL

Statistical Methods in Scientific Inference

It is regrettable that Edwards's interesting article[1], supporting the likelihood and prior likelihood concepts, did not point out the specific criticisms of likelihood (and Bayesian) concepts that seem to dissuade most theoretical and applied statisticians from adopting them. As one whom Edwards particularly credits with having "analysed in depth . . . some attractive properties" of the likelihood concept, I must point out that I am not now among the "modern exponents" of the likelihood concept. Further, after suggesting that the notion of prior likelihood was plausible as an extension or analogue of the usual likelihood concept (ref. 2, p. 200), I have pursued the matter through further consideration and rejection of both the likelihood concept and various proposed formalizations of prior information and opinion (including prior likelihood). I regret not having expressed my developing views in any formal publication between 1962 and late 1969 (just after ref. 1 appeared). My present views have now, however, been published in an expository but critical article (ref. 3, see also ref. 4), and so my comments here will be restricted to several specific points that Edwards raised.

If there has been "one rock in a shifting scene" or general statistical thinking and practice in recent decades, it has not been the likelihood concept, as Edwards suggests, but rather the concept by which confidence limits and hypothesis tests are usually interpreted, which we may call the confidence concept of statistical evidence. This concept is not part of the Neyman–Pearson theory of tests and confidence region estimation, which denies any role to concepts of statistical evidence, as Neyman consistently insists. The confidence concept takes from the Neyman–Pearson approach techniques for systematically appraising and bounding the probabilities (under respective hypotheses) of seriously misleading interpretations of data. (The absence of a comparable property in the likelihood and Bayesian approaches is widely regarded as a decisive inadequacy.) The confidence concept also incorporates important but limited aspects of the likelihood concept: the sufficiency concept, expressed in the general refusal to use randomized tests and confidence limits when they are recommended by the Neyman–Pearson approach; and some applications of the conditionality concept. It is remarkable that this concept, an incompletely formalized synthesis of ingredients borrowed from mutually incompatible theoretical approaches, is evidently useful continuously in much critically informed statistical thinking and practice.

While inferences of many sorts are evident everywhere in scientific work, the existence of precise, general and accurate schemas of scientific inference remains a problem. Mendelian examples like those of Edwards and my 1969 paper seem particularly appropriate as case-study material for clarifying issues and facilitating effective communication among interested statisticians, scientific workers and philosophers and historians of science.

PHYSICAL SCIENCES

Redshifts of Companion Galaxies

Since 1966 (ref. 1) there has been observational evidence[2-4] that quasi-stellar radio sources (QSRs) and compact radio galaxies are ejected from galaxies. Whatever distance scale one uses, one of the characteristics of QSRs and compact radio galaxies is that a great deal of energy is compressed into very small dimensions. Unless very special conditions prevail, such concentrated sources would be expected to expand with time. Indeed, the short lifetimes which are inferred from their rapid rate of energy expenditure, the associated jets of material and the prevalence of ejected radio pairs across the sources all attest to expansion and eruption.

We would therefore expect that when a compact object which is initially not optically resolvable (that is, a QSR or a QSO) expands sufficiently it eventually must become resolvable (a compact galaxy). As it continues to expand we would expect the surface brightness to diminish and eventually the object should look only slightly more compact than a galaxy of normal surface brightness. I have recently reported results[5] which lead to the conclusion that compact galaxies and companion galaxies in general have also been ejected from large, central galaxies. The observations also indicate that the ejections are initially very compact and rapidly expand. The model which suggests itself is one where matter is ejected in a compact, QSR-like form, which evolves into a compact radio galaxy and finally into a less and less compact companion galaxy. (This is, of course, an evolutionary interpretation. As far as the observational evidence goes, one may simply wish to consider that smaller bodies, with a continuity of properties that reaches to the extremes of QSRs, are associated with large, normal galaxies.)

It is usually assumed in astronomy that galaxy redshifts are only due to Doppler, velocity shifts. Objects which differ greatly in redshift are always presumed to be at different distances so as not to violate the (expansion) velocity–distance relation. The only way such an assumption could be shown to be incorrect would be to demonstrate that objects of greatly different redshifts cluster together on the sky. The observational evidence on the QSRs and radio compact galaxies referred to simply argues that they do in fact cluster on the sky around lower redshift galaxies and tend to be aligned and paired across these galaxies.

The proposed continuity of characteristics of the ejected compact bodies, however, suggests another kind of test on the nature of their redshifts. We can investigate smaller companions around galaxies, companions which astronomers have long accepted as belonging to the central galaxy and being at essentially the same distance as the larger galaxy. If the intrinsic redshift evolves from high to low as ejected objects evolve toward brighter and less compact companions, then we would expect even the normally accepted companions to have at least some small residual, excess redshift left. Even if there is no evolution involved and it is simply the case that objects of various redshifts are ejected, we would still expect the companion galaxies to have somewhat higher redshifts, on the average, than the parent galaxy.

In order to test this prediction I have listed in Table 1 all the galaxies having companions which are unquestionably accepted as belonging to the larger galaxies. The Andromeda Nebula and the four well known companions that fall within 15 arc degrees are listed, followed by the M81 and NGC 5128 groups with the members as defined by de Vaucouleurs[12]. In eleven out of these thirteen cases the companion galaxies have higher redshifts than the central galaxies.

The data for the first three groups are taken from redshifts, corrected for galactic rotation, listed by de Vaucouleurs and de Vaucouleurs[6]. These redshifts represent, for the most part, means of two or more optical determinations. The independent determinations usually agree within about 20 km s^{-1}. In addition, there are redshifts from radio (21 cm) observations for five of the objects which confirm the optical redshifts to within about this same accuracy. Mean errors of the redshifts in the first part of Table 1 may be obtained from the weights listed in column 23 of the de Vaucouleurs Reference Catalogue. Of course, the errors of measurements, like orbital or ejection velocities around the central galaxy, will simply spread the distribution of redshifts around their mean value. The important point, as Fig. 1 indicates, is whether the mean residual redshift is significantly different from zero in terms of the dispersion regardless of the cause of that dispersion.

Also listed in Table 1 are six spiral galaxies with companions on the ends of arms[5]. These can be included because the connexion to the companion galaxy ensures that the companion is at the same distance as the main galaxy. The listed redshifts represent all that I know of in this class of galaxies.

Altogether the redshift of the companion galaxy is higher than that of the main galaxy in sixteen out of nineteen cases in Table 1. This could occur by accident in less than two out of a thousand chances. If we were to continue to interpret the entire redshift of each companion as a velocity shift, we would have an absurd situation where the companions were systematically receding from the main galaxy along our line of sight to that main galaxy.

It should be emphasized that Table 1 represents a conservative assignment of companion galaxies. For example, NGC 404 (not listed in Table 1) is situated on a line between M31 and M33, and is believed to be a companion of M31 (refs. 4 and 12). Its redshift is +237 km s^{-1} greater than M31.

Table 1. GALAXIES KNOWN TO BE COMPANIONS OF LARGER GALAXIES

Dominant galaxy	Companion galaxy	Differential redshift (km s^{-1})
M31	M32	+85
	NGC 205	+62
	NGC 185	+58
	M33	+57
M81	M82	+234
	NGC 2976	+81
	NGC 3077	−104
	IC 2574	+91
	HO II	+215
NGC 5128	NGC 5102	+77
	NGC 5236	+64
	NGC 5253	−42
	NGC 5068	+139
M51	NGC 5195	+109
Atlas 48	Companion	−120
Atlas 58	Companion	+60
Atlas 82	Companion	+90
Atlas 86	Companion	+23
Atlas 87	Companion	+180

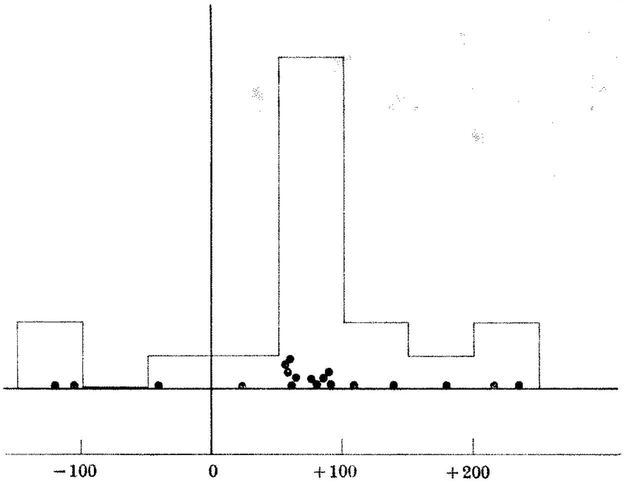

Fig. 1. Residual redshifts of nineteen galaxies known to be companions of larger galaxies.

Of the three negative redshifts, the two most negative are questionable for the following reasons. (1) The companion to Atlas 49 registers only emission lines which may well come from material in the disk of the parent galaxy excited by the object which appears to be in the process of ejection. There is therefore no assurance that the measured redshift really represents the intrinsic redshift of the compact companion. (2) NGC 3077 forms a pair with M82 on either side of M81. If we consider them to be an ejected pair, the mean of their redshifts is +65 km s^{-1}. This is just about the expected redshift of these kind of companions as judged from Fig. 1. The remaining redshift would then represent a separation of about 170 km s^{-1} in mutually opposite directions from M81.

Table 1 essentially exhausts those cases where redshifts are known in groups where we are certain that the smaller companions belong to the large central galaxies. If we try to extend this list we encounter groups where there are a number of galaxies of comparable size and therefore it is not certain which are the companions and which are the main galaxies. We also encounter looser groups in which membership is less certain. Of the five nearest groups which de Vaucouleurs[12] lists, three are represented in Table 1. Of the remaining two, the Sculptor Cloud is a loose group of comparable Sc to Sm nebulae. (Nevertheless the faintest member of the group, NGC 45, has a redshift about 400 km s^{-1} greater than the group mean.) The other group, the Canes Venatici I Cloud, is very heterogeneous and overlaps with various, presumably more distant, groups in that general direction in the sky.

Although, as I have mentioned, clusters of galaxies represent a somewhat different situation than dominant galaxies with companions, if we investigate some of the fainter clusters we find further evidence for fainter galaxies in the clusters tending to have higher redshifts. Holmberg[7] demonstrated that there is an increasing redshift with increasing faintness among galaxies belonging to the Virgo cluster. It is well known that late type (young population) spiral galaxies in Virgo tend to have considerably higher redshifts than the mean of the cluster[13]. Even when we exclude Sc spirals, however, the remaining Virgo cluster galaxies still show a correlation of redshift with apparent magnitude (unpublished results).

The same situation is true with respect to the four largest groups listed in Humason, Mayall and Sandage[8]

(G383, Leo, G5846 and G7619). The first of these groups in particular, the galaxies involved in the Markarian chain centred on NGC 383, shows a marked correlation of higher redshifts with fainter magnitudes. Recently Sargent[9] reported one of the fainter galaxies in another chain to have an excess redshift of considerable magnitude, and earlier I argued[10] that IC4296 was a member of the NGC 5128 chain despite a considerably higher redshift.

The slope of the excess redshift–magnitude relation looks steeper (in km s^{-1} per magnitude) for clusters than it does for the dominant-galaxy-with-companions case treated in Table 1. It might have something to do with the possibility of larger galaxies fragmenting[11,14], which would make each original, low redshift fragment fainter and thus steepen the relation. It may also be related to the much higher dispersion of redshifts which is encountered in the more distant clusters. Much higher redshift objects are therefore included as members of clusters and the slope can thus be much steeper. The higher dispersion of velocities, of course, makes the cluster membership criterion generally more dependent on areal projection on the cluster area. The generally small differences in redshift between the main galaxies and companions in Table 1, on the other hand, are added confirmation of their accepted group membership.

In conclusion, the systematically higher redshifts for the companion galaxies supports the conclusion that compact, intrinsically higher redshift objects are ejected from nearby galaxies. At the same time it contradicts the current assumption that galaxy redshifts are only due to Doppler velocities. That is, it observationally contradicts exactly that principle which has been invoked to reject the previous observational evidence for association of high and low redshift objects.

Low-frequency Spectrum of the Crab Nebula

THE compact low-frequency radio source[1] in the Crab nebula is exceptional in most of its properties. Its spectral index[2] of ~1·75 between 26·5 and 1,407 MHz is the highest known for a galactic continuum source, and its brightness temperature of ~10^{14} K at 38 MHz implies an unusual emission mechanism with a high volume emissivity. The high spectral index suggests that only a small fraction of the total radio luminosity of the source may have been observed in the frequency range studied so far. The error field of its radio position[3] contains the pulsar NP 0532, and these objects may therefore be related; if the relationship were substantiated, it would be the only continuum source of small angular size known to coincide with a pulsar. This report presents evidence that the high spectral index is maintained to 10 MHz.

Observations of the flux density of radiation from the Crab nebula at frequencies below ~40 MHz must be corrected for absorption by free-free transitions of electrons in the intervening interstellar medium to determine the spectrum of the emitted radiation. The interstellar absorption along the 2,020 pc line of sight[4] to the nebula ($l^{\text{II}}=184^\circ\cdot6$, $b^{\text{II}}=-5^\circ\cdot8$) can be estimated from low-frequency studies of other continuum radio sources at low galactic latitudes, and also from 21 cm line observations of the interstellar medium on this line of sight.

Observations[5] of discrete radio sources at 10 MHz have recently been used to define models of the low frequency absorption by the interstellar medium. The 10 MHz optical depth of the line of sight to the Crab nebula predicted by a uniform-disk model[6] of the interstellar electron gas is $\tau(10)=0\cdot68\pm0\cdot17$. A non-uniform model[7] which allows for differences in the absorption coefficient $\varkappa(10)$ between the local spiral arm and the inter-arm region predicts $\tau(10)=0\cdot62\pm0\cdot17$ on this line of sight. These predictions are derived from the same 10 MHz data and are not independent; the agreement between them indicates that the expected value of $\tau(10)$ on this line of sight is only weakly dependent on the model used to interpret the 10 MHz data.

The optical depth $\tau(10)$ of the line of sight to IC443, which is 1,500 pc (ref. 8) from the Sun in the direction $l^{\text{II}}=189^\circ\cdot0$, $b^{\text{II}}=+3^\circ\cdot2$, should be similar to that of the line of sight to the Crab nebula and the value observed[7], $\tau(10)=0\cdot65\pm0\cdot25$, agrees with the other estimates.

Hjellming *et al.*[9] have estimated the electron density and temperature within interstellar clouds and the inter-cloud medium on the line of sight to the Crab nebula from the 21 cm absorption of the nebular continuum. The optical depth $\tau(10)$ calculated from their data on this line of sight is $0\cdot42\pm0\cdot10$, with approximately equal contributions from clouds at ~50 K and from the inter-cloud medium at ~1,000 K.

Table 1. CORRECTIONS FOR INTERSTELLAR ABSORPTION AT LOW FREQUENCIES

Frequency (MHz)	Measured intensities multiplied by

26·3	1·08
35	1·04
38	1·04
81·5	1·01

Observations of the integrated flux density of the Crab nebula at low frequencies[5,10–15] have been corrected for interstellar free-free absorption by assuming that $\tau(10)=0\cdot6$ on the line of sight, and calculating the corresponding optical depths at higher frequencies from the relation $\tau(\nu)=k\nu^{-2}[17\cdot7+\ln(T^{3/2}\nu^{-1})]$. The corrections at each frequency are given in Table 1. Fig. 1 shows the estimated spectrum of the radiation leaving the nebula between 10 and 15,500 MHz. The spectrum shows an enhancement of the total radiation at low frequencies which is consistent with a power-law extrapolation of the spectrum of the compact source to 10 MHz; a marginally significant enhancement is noticeable in the uncorrected data.

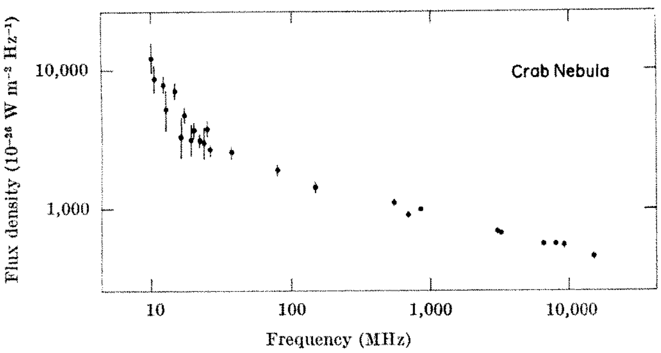

Fig. 1. The emission spectrum of the Crab nebula between 10 and 15,500 MHz, corrected for interstellar absorption. Some pairs of measurements at similar frequencies have been slightly separated along the frequency axis to clarify the figure.

The contribution of the compact source at the lowest frequencies can be estimated from Fig. 1 if it is assumed that the diffuse nebular emission maintains its high-frequency power-law spectrum throughout the low frequency range. The most probable departure from this spectrum would be reduction of the spectral index at low frequencies due to free-free absorption or electron energy losses within the nebula, in which case this analysis would underestimate the low-frequency emission from the compact source, and hence its spectral index, luminosity and brightness temperature.

The spectrum of the nebula at frequencies above 80 MHz was fitted with a power law using a least-squares procedure. The 10 and 15 MHz intensities extrapolated from this power law were subtracted from the mean spectrum defined by the low-frequency measurements to estimate the contributions of the compact source at these frequencies. Intensities so estimated would be unreliable at frequencies above 20 MHz, but the spectrum of the compact source is defined at these frequencies by observations[1,2] at 26·5, 38, 81·5 and 1,407 MHz. Bell and Hewish[2] have suggested that the intensity of the compact source derived from the 26·5 MHz occultation observation of Andrew *et al.*[1] is invalid, for the position of the source given by this observation disagrees with the subsequent measurement by Gower[3]. This discrepancy may be resolved by rejecting the 26·5 MHz emersion record, which was seriously affected by terrestrial interference[1]. The position of the limb of the Moon at the immersion was consistent with the later result, and the 26·5 MHz intensity derived from the interference-free immersion record should be valid. This interpretation of the 26·5 MHz occultation data suggests that the compact source is feature "2" in the nomenclature proposed by Matveenko[16].

Table 2. FLUX DENSITIES OF THE COMPACT SOURCE IN THE CRAB NEBULA

Frequency (MHz)	Flux density (10^{-26} W m^{-2} Hz^{-1})	Reference
10	6,900 ± 2,200	This paper
15	2,120 ± 700	This paper
26·5	1,230 ± 150	1
38	486 ± 50	2
81·5	190 ± 20	2
1,407	< 0·9	2

The spectrum derived for the compact source (Table 2) can be represented by a power law of index $\alpha = 1{\cdot}76 \pm 0{\cdot}15$ from 10 to 1,407 MHz. The luminosity of the source between 10 and 1,407 MHz is $\sim 3 \times 10^{32}$ erg s^{-1}, which is about ten times that of the pulsar NP 0532 at radio frequencies, but only one-tenth of its luminosity at optical frequencies. The angular diameter of the compact source is known to be $\sim 0{\cdot}2$ arc s from studies of its interplanetary scintillation[2] at 81·5 MHz. Its brightness temperature at 10 MHz would be as high as $\sim 3 \times 10^{15}$ K if the diameter were the same at this frequency, which leaves little doubt that the source cannot radiate by the electron synchrotron mechanism: the magnetic field strength within the source would be $< 6 \times 10^{-8}$ G and the total energy of relativistic electrons alone would be $> 4 \times 10^{51}$ erg, assuming the source to be homogeneous.

Rees[17] has suggested that the emission may be proton synchrotron radiation emitted at a frequency below the electron gyrofrequency. The 10 MHz parameters then imply a magnetic field strength $< 0{\cdot}4$ G, a total magnetic field energy $< 8 \times 10^{44}$ erg, and a total proton energy $> 1{\cdot}5 \times 10^{47}$ erg, again assuming a homogeneous source. The proton synchrotron model is attractive, for it requires field and particle energies which are modest in comparison with the total energy supply of the nebula, and which could be stabilized by the gravitation of an object of mass $\sim 1\ M_{\odot}$, as pointed out by Burbidge and Hoyle[18]. The magnetic field and proton flux required on this model of the compact source may be associated with the outer magnetosphere of the pulsar. A magnetic field of strength $< 0{\cdot}4$ G gives an electron gyrofrequency $< 1{\cdot}2$ MHz, however, so Rees's interpretation[17] cannot be maintained if there are electrons present in the region of the source, as these would absorb the proton radiation.

Alternatively, the high brightness temperature of the compact continuum source might be attributed to a coherent plasma oscillation[19] or to radiation from a synchrotron maser[20]. In either case the characteristic frequency associated with the mechanism must be < 10 MHz, and the total energy output must therefore appreciably exceed the 3×10^{32} erg s^{-1} detected by the present observations, unless the emission were anisotropic.

It is possibly significant that the spectral index of the mean radio pulse[21] from NP 0532 is ~ 2 at 196 MHz, comparable with the spectral index of the continuum source at lower frequencies. The equivalent continuum flux density of the pulsar is ~ 20 per cent of that expected for the compact source at 196 MHz. The intrinsic pulse width from NP 0532 increases with decreasing frequency below 150 MHz (reports by Drake and by Sutton *et al.*, at the 131st meeting of the American Astronomical Society, New York, 1969), and furthermore the high dispersion of the pulses results in large numbers being instantaneously superimposed in the bandwidths of most low-frequency instruments. It would therefore be difficult to distinguish between NP 0532 and a continuum source at low frequencies.

The apparent angular diameter of 0·2 arc s observed for the compact source at 81·5 MHz may exceed its true diameter due to scattering of its radiation by density irregularities in the interstellar electron gas if the typical density fluctuations ΔN(cm^{-3}) and their scale a (cm) were related[22] as $\Delta N \sim 2 \times 10^{-9}\ \sqrt{a}$. This condition is quite likely to be satisfied in the interstellar medium. The true diameter of the source might therefore be $< 0{\cdot}2$ arc s and the brightness temperature at 10 MHz $> 3 \times 10^{15}$ K, which would increase the difficulties associated with a proton synchrotron model of the source. This could be investigated by long-baseline interferometry or interplanetary scintillation studies of the compact source at very low frequencies; if the apparent diameter were simply that imposed by interstellar scattering, it would be found to increase as the square of the observing wavelength. Such observations, and an improved position for the compact source, will be important for theories of the source and of its relationship to NP 0532.

Anomalous Rhenium Isotopic Ratio in the Solar Wind: Detection at the Nanogram Level

CLAYTON[1] recently considered an apparent anomaly in the ^{187}Re–^{187}Os cosmochronology. He showed that this could be resolved if the half life of ^{187}Re was significantly shortened in a stellar environment, and considered the solution to lie in the bound beta decay process, which is energetically feasible for the weak ^{187}Re transition[2]. The ionization of Re in the outer solar convective zone increases the number of vacant bound states available, and Clayton suggests a reduction in the total ^{187}Re half life from 43×10^9 yr to about 3×10^9 yr. It might therefore be expected that the ^{187}Re/^{185}Re ratio in the solar wind would be between one-half and one-third that observed terrestrially. Clayton proposed that the hypothesis could be tested by measuring the isotopic ratio of Re in the surface layer of an old part of the lunar regolith, and stressed that "this measurement should eventually be undertaken if there is any reasonable chance of detection". In this article I suggest a simple sensitive method to detect the expected isotopic anomaly.

The solar wind flux of Re is given[1] as 10^{-3} atoms cm^{-2} s^{-1}, which deposits approximately 10^{-8} (g Re) cm^{-2} in 10^9 yr. To estimate the likelihood of detection the probable Re abundance of the lunar surface must first be considered. The preliminary examination of Apollo 11 samples[3] shows only that Re is below the spectrographic detection limit of 10^{-4} g g^{-1}. For the present discussion it is supposed that the Re content of lunar material might resemble that of terrestrial basic rocks on the one hand, or the achondrites on the other. Re has been measured in some basic and ultrabasic rocks and abundances lie generally between 10^{-9} and 10^{-10} g Re g^{-1} (ref. 4). Very few Re abundances are known for achondrites; however, some hitherto unpublished analyses are given in Table 1. These abundances lie within a range similar to that found for terrestrial rocks. Lunar rocks examined to date[3] are unusual for a very high Ti abundance. No achondrite is enriched in this element to quite the same extent, but a reasonably high abundance is found in the Angra dos Reis achondrite. The enrichment of Ti in this meteorite does not seem to be accompanied by a similar Re enrichment. It is reasonable to suppose, therefore, that an upper limit for the Re content of lunar material would be about 10^{-9} g g^{-1}.

Table 1. RHENIUM ABUNDANCES IN SOME ACHONDRITIC METEORITES

Achondrite	Re 10^{-10} g g^{-1}	
Bishopville (aubrite)	$2 \cdot 2 \pm 0 \cdot 1$ $2 \cdot 8 \pm 0 \cdot 1$	2·5
Johnstown (diogenite)	$12 \cdot 8 \pm 0 \cdot 2$ $2 \cdot 6 \pm 0 \cdot 2$	7·7
Ellemeet (diogenite)	$0 \cdot 6 \pm 0 \cdot 1$ $1 \cdot 3 \pm 0 \cdot 1$	0·9
Moore County (eucrite)	$0 \cdot 3 \pm 0 \cdot 1$ $0 \cdot 9 \pm 0 \cdot 1$	0·6
Binda (howardite)	$0 \cdot 8 \pm 0 \cdot 4$ $\leqslant 0 \cdot 7$	0·7
Nakhla (nakhlite)	$\leqslant 0 \cdot 6$ $0 \cdot 9 \pm 0 \cdot 1$	0·8
Angra dos Reis (angrite)	$0 \cdot 6 \pm 0 \cdot 1$ $0 \cdot 8 \pm 0 \cdot 1$	0·7

Clayton feared that the Re abundance of the lunar surface might be prohibitively enhanced from contamination by chondritic material, which has an average abundance of roughly 5×10^{-8} g Re g^{-1} (refs. 5 and 6). In most common chondrite groups, Re is predominantly concentrated in the Ni–Fe phase[5] and Clayton apparently interprets the high Fe abundance in lunar material as indicating Re enrichment. This is unlikely, for Fe in the lunar rocks occurs chiefly as ilmenite, and in the major silicates. Troilite and native Fe have been tentatively identified but are present in very small amounts. In any event, a simple magnetic separation could be used to remove metal or troilite if present in significant quantities.

Estimates of the concentration of solar wind Re depend on the model used. In crystalline rocks, solar wind enrichment will be largely a surface effect. If the rocks are continuously ablated, the Re concentration will depend on the erosion rate, and equilibrium could be reached in considerably less than 10^9 yr. Conservatively estimating an equilibrium exposure time of 10^6 yr, and assuming quantitative Re retention, 10^{-11} g Re cm^{-2} will be implanted. If a surface layer 0·1 cm thick is sampled, the solar wind contribution will be 10^{-10} g Re cm^{-3}, or approximately 3×10^{-11} g Re g^{-1}. Thus, even for this very short exposure time, an Re isotopic anomaly of 1 per cent more could be expected. It is possible that the rounded shape of many lunar rocks is the result of discrete ablation events rather than continuous erosion, and in this case the solar wind exposure time could well be very long. The surface of these rocks may then contain large amounts of solar wind Re, and an isotopic anomaly of 10 per cent or more might be present.

Rather different arguments apply to the lunar soil, and these may be extended to include the lunar breccias. The exposure of the soil is not limited to the surface, and a lower limit to the implanted Re can be estimated from the lunar soil Xe abundance, which is largely of solar wind origin[3]. Assuming that Xe is quantitatively retained, a concentration of approximately 2×10^{-11} g Re g^{-1} can be obtained by simply applying the ratio of Re to Xe in solar material[7]. This estimate is pessimistic, for the retention of Re will be better than that for the rare gases under reducing lunar conditions. Solar wind Re will be more abundant relative to normal Re in the fine-grained soil fraction because of the greater surface to volume ratio.

Riley[8] has discussed the mass spectrometric determination of isotopic ratios of Re, and the difficulties resulting from the high ionization potential of this element. Some increase in sensitivity can be attained by pulse counting techniques, but the procedures detailed by Riley do not seem easily applicable to Re at the nanogram level.

The nuclear characteristics of Re are particularly favourable for its determination by neutron activation and both naturally occurring isotopes yield radionuclides of convenient half-life. The relevant nuclear properties are summarized in Table 2. For Re of normal isotopic composition, the saturation activity of the (n,γ) products of ^{185}Re and ^{187}Re are approximately $1 \cdot 3 \times 10^4$ and $1 \cdot 5 \times 10^4$ disintegrations s^{-1} for 10^{-8} g Re and a thermal flux of 10^{13} neutrons cm^{-2} s^{-1}. It is possible, therefore, to determine the isotopic ratio of Re with good sensitivity. In principle the gamma rays can be used for the ratio

Table 2. NUCLEAR DATA FOR THE NEUTRON ACTIVATION DETERMINATION OF RHENIUM ISOTOPIC RATIOS

Target	Isotopic abundance (%)	(n,γ) cross section (barns)	Product nuclide	Half lif	Beta energy (MeV)	Gamma energy (MeV)
^{185}Re	37·07	110	^{186}Re	88·9 h	1·07 (95%)	Os X-ray 0·137 (9%)
^{187}Re	62·93	1·3	^{188m}Re	18·7 min	—	
		70	^{188}Re	16·7 h	2·12	Os X-ray 0·155 (10%)

determination, but have rather small branching ratios. Fortunately the beta rays are sufficiently energetic to be counted with little interference from source self-absorption. The isotopic ratio can then be derived by comparison of the decay curves of a radiochemically purified Re source from a lunar specimen, with that of a standard of normal, or known, isotopic ratio.

If the expected isotopic anomaly can be demonstrated it will not only verify Clayton's hypothesis but would be of considerable value in determining relative deposition rates of the lunar regolith and ablation rates of lunar rocks.

I thank an anonymous referee for his suggestions. This work was supported in part by a NASA contract.

Longitudinal Structure in the Plasmapause: VLF Goniometer Observations of Knee-whistlers

A PRELIMINARY study of knee-whistlers observed in the late morning of a quiet day, July 26, 1967, 1206–1236 UT ($K_p = 2-$), by means of a wide-band (0·5 to 11 kHz) VLF goniometer receiver at Halley Bay (333·4° E of N, 75·52° S, generalized invariant latitude at 100 km: $\Lambda' = 61 \cdot 02°$) has revealed the existence of marked longitudinal variation ($\sim 3:1$) in electron tube content on an L-shell ($L \simeq 4 \cdot 7$–$4 \cdot 8$) just outside the plasmapause.

The VLF goniometer receiver installed at Halley Bay, Antarctica, in 1967 consisted of two vertical diamond (30 foot × 30 foot) loops mounted at right angles to each other. From these two loops an equivalent vertical loop, rotating at a frequency of 25 cycles s^{-1}, was simulated electronically. If the electromagnetic wave detected by the equipment has travelled some distance in the Earth–ionosphere waveguide, so that the transverse magnetic mode is dominant, then the modulation of the signal amplitude by the rotating loop (see Fig. 1*a*) may be used to determine the azimuth of the source. The crossed loop technique of determining the azimuth of a whistler exit point is imprecise, chiefly because of bearing errors introduced by multiple rays (J. H. Crary, unpublished) and signal fading. Nevertheless, provided the whistler duct exists long enough to yield a number of bearings determined over a range of frequencies, it is possible to distinguish vetween latitudinal and longitudinal structure in the magnetosphere.

During the period under study the whistlers in ducts near the plasmapause fell into eight groups (Table 1), two of which (N_1, N_2) occurred just inside the plasmasphere at $L \simeq 4 \cdot 2$; the remainder, knee-whistlers, occurred just outside at $L \simeq 4 \cdot 7 - 4 \cdot 8$. The analysis was on sonagrams as illustrated in Fig. 1. In Fig. 1*a* the sonagraph bandwidth ($\Delta f = 300$ Hz) is optimized for bearing determination whereas in Fig. 1*b* a narrower bandwidth ($\Delta f = 45$ Hz) is used to help determine nose frequency and whistler dispersion. For a short period (1222–1224 UT) the whistler groups occurred simultaneously, so it was possible to determine the relative travel times at the nose frequencies (f_n) rather precisely. In the absence of a positive identification of the associated sferic the absolute travel times (t_n) at the nose frequencies were obtained by curve-fitting. The latter calculations were carried out using the "diffusive equilibrium" and "collisionless (R^{-4})" models of the magnetosphere for the normal and knee-whistlers respectively. The treatment followed closely that outlined by Angerami and Carpenter[1] and Angerami (unpublished), except that a more up-to-date model of ion and temperature distribution in the magnetosphere (presented by Rycroft and Alexander at the Prague COSPAR meeting, 1969) was used.

A mean azimuth was determined for each rotation of the loop, up to four individual measures (two minima, two maxima) being made in each rotation. Each azimuth thus determined was weighted according to the number (1 to 4) of individual measures in the rotation and an overall weighted mean for the group calculated. Histograms of the measurements are shown in Fig. 2. The standard deviation (Table 1) as indicated by the histograms is large; nevertheless, there are significant differences in the azimuthal bearings of the exit points of the knee-whistlers.

The generalized invariant latitude (Λ') for an altitude of 100 km was calculated for each group. It is clear that all the knee-whistlers occurred in ducts lying very close (within $\pm 0 \cdot 3°$) to the same L latitude. The contours of $\Lambda' = 60°$, $65°$ shown in Fig. 3 were obtained from tables provided by Jacka[2] and the values of Λ' in Table 1 plotted by interpolation. The points plotted in Fig. 3 indicate the intersection of the mean bearing of a group with its appropriate contour of L latitude. The azimuthal bearing obtained for K_4 did not intersect the appropriate L latitude, but considerations of signal attenuation with distance travelled in the Earth–ionosphere waveguide make

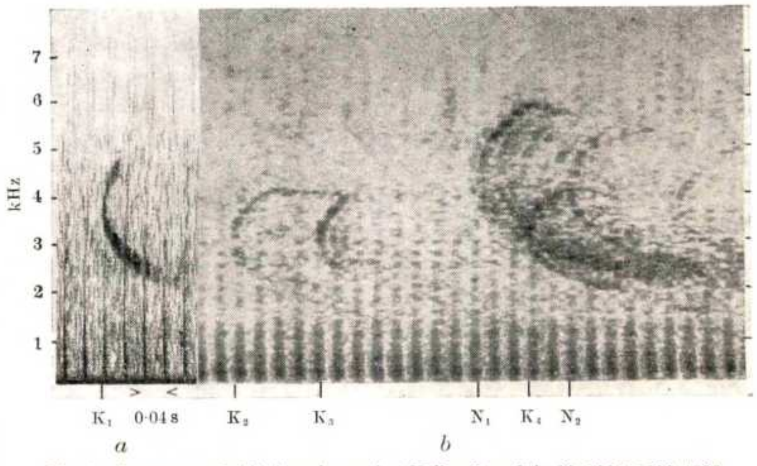

Fig. 1. Sonagrams of whistlers observed at Halley Bay, July 26, 1967, 1206–1236 UT. For a plane electromagnetic wave (transverse magnetic) propagating along the N–S meridian the leading edge of the calibration marker is coincident with a minimum in the signal intensity. *a*, Knee-whistler K_1; sonagraph bandwidth, 300 Hz. *b*, Knee-whistlers K_2, K_3, K_4 and normal whistlers N_1, N_2; sonagraph bandwidth, 45 Hz.

Table 1. GROUPING OF THE WHISTLERS

Whistler group	Period of activity (UT)	No. of whistlers	Mean t_n (s)	Mean f_n (kHz)	Mean L	Mean Λ' (deg.)	No. of measurements of azimuth	Weighted mean azimuth °E of N	R.m.s. deviation (deg.)	N_{eq} ($\times 10^2$ cm^{-3})	Tube content* N_T (electrons cm^{-2}-tube)
N_1	1,210–26	19	2·05	4·55	4·20	60·5	175	66·1	± 17	3	3×10^{14}

it likely that the exit point did not lie at a range much in excess of that where the dashed line (K_4'), corresponding to one standard deviation (17°), intersected the L latitude, $\Lambda' = 62{\cdot}45°$. Measurement of the bearing of K_4 was difficult because the whistler was superposed on that of N_1 (Fig. 1*b*). The bearing of N_1 lay rather close to a tangent to the L latitude contour, so there was ambiguity and it could have occurred to the west of Halley Bay at N_1'. The fact that the most intense knee-whistlers were those of K_1 is consistent with its being the nearer duct.

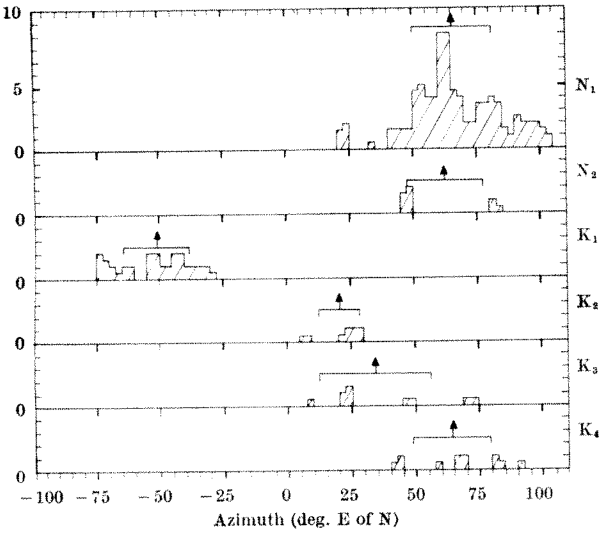

Fig. 2. Histograms of measurements of the azimuth of whistler exit points. The arrows show the weighted mean azimuth.

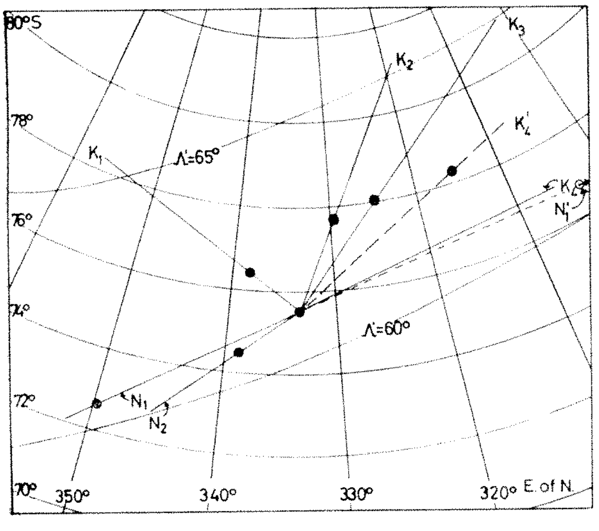

Fig. 3. Map showing probable location of the whistler exit points relative to Halley Bay and the contours, $\Lambda' = 60$, 65°, of generalized invariant latitude for an altitude of 100 km

The values of equatorial electron density and tube content (electrons cm^{-2}-tube) in Table 1 were obtained from the graphs of Angerami for the values of t_n, f_n shown. It can be seen that the equatorial electron density decreased by an order of magnitude across the plasmapause while the tube content dropped ten to fifty times. These values are typical of those obtained by Carpenter and his co-workers. The position of the plasmapause, as might be expected, is slightly to the south of its mean location ($L = 3{\cdot}7$) at this local time (1020 − 1050 LT) on days of moderately steady agitation ($K_p = 2$ to 4) (ref. 3). Especially interesting is the marked longitudinal variation of 3 : 1 in the tube content as we move westward along the same L shell from K_1 to K_4' on Fig. 3. Clearly, the existence of such structure must be borne in mind in the interpretation of knee-whistlers and merits the use of a goniometer to distinguish such features from the latitudinal multilevel structure which has been observed by satellites during magnetic storms.

A more comprehensive study of these and related observations on the same day will be published elsewhere.

We thank the personnel of the British Antarctic Survey, especially Messrs J. Jamieson and W. Laidlaw, for the installation and operation of the equipment at Halley Bay, and Professor T. R. Kaiser for encouragement and advice. One of us (J. L. S.) received a fellowship from ESRO.

Strength–Modulus Relation for Carbonized Acrylic Fibres

THE Young's modulus of carbon fibres based on a single commercial acrylic steadily increases with increasing process temperature[1-3], and reaches 30×10^6 pounds/inch^2 at a final processing temperature of 1,000° C. A corresponding relation for the breaking strength of the fibres shows a peak in strength at either 1,500° C (ref. 1) or 1,200° C (refs. 2 and 3), giving the high breaking strain (1·3 per cent) type of fibre, followed by a decrease in strength at higher processing temperatures. Tests of strength versus gauge length[1,4] have shown that weak spots or flaws influence the breaking strength of the fibres, and this is illustrated, at least for the high strain type of fibres, by microscopy and fractography[2,3,5]. Any relationship between strength and modulus, which has a positive slope, seems to be limited to the processing temperature range 500°–1,000° C. In this temperature range particularly, mechanical properties of the fibres are influenced by the processing conditions and by the nature of the starting material. Any material or processing condition which allows fusion or gross disruption of the pyrolysing

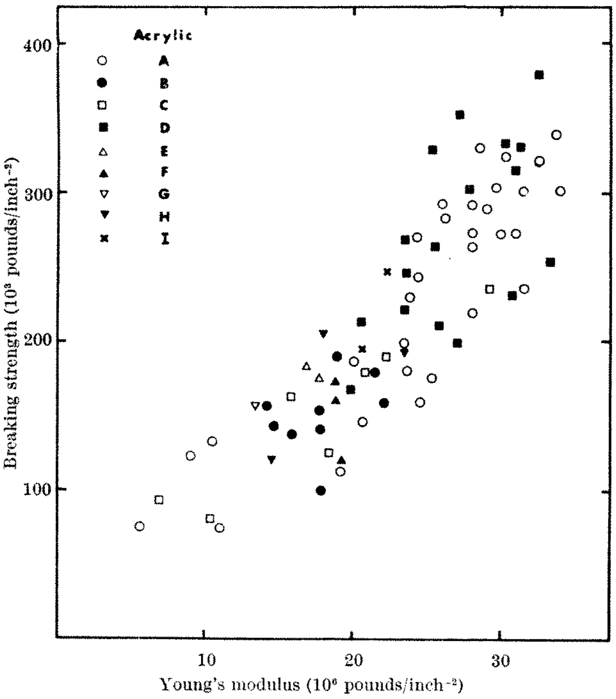

Fig. 1. Breaking strength versus Young's modulus of carbon fibres from various acrylics, variously processed to 1,000° C.

polymer will lead to incoherent carbon fibre with poor mechanical properties.

We show here a positive relationship between breaking strength and Young's modulus of carbon fibres, which is illustrated for a variety of acrylic precursors processed to 1,000° C using a variety of processing conditions. Nine acrylics, one experimentally produced and eight which are commercially available, were processed by the well known techniques of pre-oxidation at 200°–300° C followed by pyrolysis in an inert atmosphere to 1,000° C. The rates of processing during the two stages were varied to optimize the mechanical properties of the resultant carbon fibres. The fibres were submitted to a tensile test at room temperature, using a gauge length of 2·3 cm, to determine both Young's modulus and breaking strength. Usually twelve or more fibres were tested to obtain mean values of modulus and strength. Cross-sectional areas of round fibres were determined from diameters measured by optical microscopy and those of irregularly shaped fibres[5] from optical or scanning electron micrographic enlargements of the fractured ends.

Mean Young's moduli and strengths for the carbonized acrylics are shown in Fig. 1. Although there is a large scatter, a positive relationship between strength and modulus is shown, with a correlation coefficient of 0·86. The relationship applies to a wide range of commercial acrylics, containing a variety of co-polymers and spun by a variety of methods[6]. The main conclusion is that, over the modulus range shown, the fibres have a fairly constant breaking strain of approximately 1·0 per cent, which is not likely to be increased substantially, except by improving strength independently of modulus.

The scatter in the correlation largely results from the influence of flaw mechanisms of fracture on the breaking strength. Flaws operative at this stage of processing have previously been described as surface flaws of obscure identity and internal flaws of known identity[2,3,5,7]. The level of Young's modulus must be specified before the effect of such flaws on the strength of carbon fibres processed to around 1,000° C can be assessed. Moreover, if two or more samples of fibre with different flaw concentrations[7] or simply with different precursor identities are compared on the basis of breaking strength, they must be processed to a similar level of Young's modulus.

A discussion of the complex effect of processing conditions (time, temperature, environment, and so on) on the level of modulus and strength achieved by the various carbonized acrylics is not within the scope of this communication. Usually, however, any processing which leads to physical disruption, as distinct from controlled chemical decomposition, of the pyrolysing polymer structure results in low strength and modulus of the carbonized fibres.

Five-fold Pseudosymmetry

IN a previous article[1] I described the properties of a non-crystallographic five-fold pseudosymmetric structure with a density of 0·7236 (compared with 0·7405 for close packing). This structure is generated by the simple process of continued packing on the close packed faces of a pentagonal pyramid (or dipyramid) nucleus (just as the continued packing on the close packed faces of a square pyramid or dipyramid nucleus results in cubic close packing[2]), and it was suggested[1] that the growth of such a pentagonal nucleus was a simple explanation for the origin of observed five-fold pseudosymmetric structures. Further discussion on the origin of pseudosymmetry is presented elsewhere[3].

There have been a number of observations of five-fold pseudosymmetry in many diverse materials[3]. In one of these observations, Allpress and Sanders[4] have tested the model by examination of the distortions in a small five-fold pseudosymmetric gold "crystal". Whereas the model[1] predicted an increase in (011) spacing (compared with face centred cubic packing), careful measurements from diffraction patterns showed a decrease of about 0·2 per cent. The authors conclude[4]: "Hence Bagley's model does not apply to the pentagonal crystals of gold, and the strain must be accommodated in some other way".

In the original model[1] the parameters were chosen so as to minimize the surface area; that is, the surfaces of the pentagonal dipyramid were assumed to be close packed. This note describes the properties of a five-fold pseudosymmetric structure which results from an alternative assumption, that of minimum volume (maximum density).

The pentagonal dipyramid consists of five distorted tetrahedra with one edge of each tetrahedron in common along the dipyramid axis (Fig. 1; see also Fig. 1 of ref. 1). Within each tetrahedron the structure is body centred orthorhombic with cell dimensions now chosen such that the volume will be a minimum (consistent with the non-overlap of the spheres) and such that two adjacent tetrahedra will be joined by a coincidence boundary. These conditions yield a body centred orthorhombic cell with dimensions (diameter of sphere = 1·000), $a = \sqrt{3}\sin 36° = 1·0181$, $b = \sqrt{3}\cos 36° = 1·4013$, $c = 1·000$). The assignment of axes is the same as in the previous

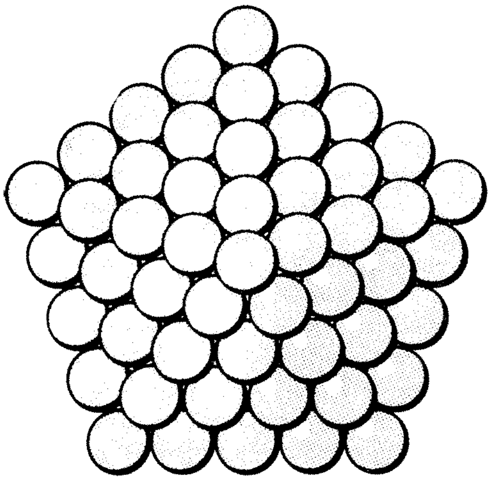

Fig. 1. View along the five-fold axis of a pentagonal structure obtained by the continued packing of hard spheres on the faces of a pentagonal dipyramid.

article[1] and the *c* axis is parallel to the five-fold pseudosymmetric axis. Thus this pentagonal structure has a density of 0·73406, independent of position. This density is slightly lower than that for close packing (0·74048), but higher than that for body centred cubic (0·68017), icosahedral shell packing (0·68818)[5] or the previous five-fold pseudosymmetric structure (0·72357)[1]. The coordination is 10 at a distance of 1·000 and 2 at a distance of 1·018. As with the previous structure, this structure is an example of G_3^1 type symmetry and its symmetry group is 5mP2ml (Niggli's nomenclature[6]).

This new structure predicts a decrease in the (011) spacing (compared with face centred cubic packing) of 0·2 per cent, in agreement with the results of Allpress and Sanders[4]. Thus we conclude that the five-fold gold structure observed by these authors resulted from the growth of a pentagonal dipyramid nucleus, and during this growth the density was maximized.

If a pentagonal dipyramid nucleus forms, either by chance or because of energy considerations[3], its continued growth will lead to a structure with five-fold pseudosymmetry. Depending on the material and growth conditions the surface area or volume may be minimized, or some balance obtained in between. Thus observed structure parameters can vary between those described previously[1] and those described here.

BIOLOGICAL SCIENCES

Effect of Phosphate and Non-phosphate Buffers on Thermolability of Unstable Haemoglobins

A GROUP of hereditary non-spherocytic anaemias have been shown to be associated with unstable haemoglobins through the application of a simple screening test for thermolability involving incubation of haemolysate at 50° C in phosphate buffer (*p*H 6·5–7·4; 0·1 M)[1-3]. Unstable haemoglobins form a precipitate within a few hours but normal haemoglobin remains in solution. We have encountered two families with this type of anaemia whose haemoglobins demonstrated little or no precipitate in these conditions, but formed copious precipitate in the presence of non-phosphate buffers—observations which led us to wonder whether the recently described effects of phosphates on the oxygen-binding properties of haemoglobin[4-7] might not also modify the heat stability of the molecule.

Most unstable haemoglobins subjected to structural analysis have revealed non-polar amino-acid substitutions at sites which would seem to affect haem–globin association adversely[8]. Access of water to a relatively loose haem–globin binding site in the presence of oxygen would promote the formation of methaemoglobin[9,10], weakening the haem–globin linkage even further[11]. Methaemoglobin formation as a precondition to heat precipitation has been an early and frequent observation in the unstable haemoglobins[1-3,12]. The developing precipitate is, for the most part, free globin, which is known to be more vulnerable to conditions of mild heating than intact haemoglobin[7].

We tested the heat stability of haemoglobin solutions prepared from affected subjects and from controls in different buffer systems following the method of Dacie *et al.*[3]. Buffers included sodium phosphate, NaCl, *tris*-(hydroxymethyl)aminomethane (Tris), Tris–maleate, sodium barbital and inositol hexaphosphate (IHP) at *p*H 7·4, in the molar range 0·001 to 1·0. Like 2,3-diphosphoglycerate (DPG), IHP is an organic polyphosphate, the chief organic phosphate in avian erythrocytes[14,15], and exerts a profound effect on the oxygen affinity of haemoglobin[4-7]. Studies were done on freshly prepared haemolysates, haemolysates dialysed exhaustively against deionized water, and haemolysates that had been allowed to age in the cold (4° C) for varying lengths of time. Incubation took place in a 50° C oven and observations were made every 30 min until visible precipitate appeared.

Table 1. PRESENCE (+) OR ABSENCE (–) OF GROSS TURBIDITY AND/OR PELLET IN BUFFERS (*p*H 7·4) CONTAINING 1 G PER CENT HAEMOGLOBIN FOLLOWING INCUBATION FOR VARYING LENGTHS OF TIME AT 50° C. HAEMOGLOBIN WAS PREVIOUSLY DIALYSED AGAINST DEIONIZED WATER

Both normal and unstable haemoglobins displayed a tendency to form precipitate more readily and more copiously in non-phosphate buffers. Whether the appearance of precipitate was recorded qualitatively (Table 1) or quantitated by the Lowry method, this phenomenon was clearly evident. In all our studies, haemoglobins from patients were more heat labile than normal haemoglobin. Phosphate buffer, however, particularly IHP, strikingly limited and retarded precipitate formation. The effect of IHP could not be attributed merely to the absence of inorganic salt, for it occurred even in the presence of varying concentrations of NaCl. Cold storage of normal and abnormal haemoglobins, both dialysed and undialysed, resulted in increased thermolability, the pattern of responses reflecting that seen in the fresh state. Like other observers, we noted the appearance of methaemoglobin coincident with precipitate formation.

If the events leading to heat precipitation involve conversion of oxyhaemoglobin to methaemoglobin with subsequent precipitation of released globin, then it is likely that the presence of phosphates interrupts this sequence by displacing oxygen from the haemoglobin molecule. In the patients studied by us, the haem–globin defect, albeit sufficient to cause haemolytic anaemia, seemed subtle enough to elude detection by the conventional procedure for screening of thermolability using phosphate buffer.

It is tempting to hope that such *in vitro* effects of organic phosphates might have some beneficial therapeutic application. Obviously, oxygenation of haemoglobin is vital for survival; it is, however, conceivable that some shift in the oxygen saturation curve might be tolerated by a person with unstable haemoglobin, particularly if it resulted in a significant reduction in haemoglobin precipitation and haemolysis. The most immediate application of our observations lies in the recommendation that non-phosphate buffers be used as a more sensitive and suitable system for the thermolabile screening test.

This work was supported in part by grants from the US National Institutes of Health and the Muscular Dystrophy Associations of America. We thank Wallace I. Sampson and Theodore Cohen for helping obtain blood samples. B. Brimhall and R. T. Jones have identified the haemoglobin in one family as Lepore (Washington–Augusta–Boston). Structural study of the other haemoglobin is in progress.

High Resolution Nuclear Magnetic Resonance Studies of Haemoglobin J Capetown

HAEMOGLOBIN J CAPETOWN[1] is a Hb variant in which one amino-acid in the α-chain, arginine α92 (FG4), is replaced by glutamine. In Hb Chesapeake[2] the same arginine is replaced by leucine, and the properties of the two variants are seen to be similar[2,3]. Compared with normal Hb A, both have increased oxygen affinities, smaller "haem-haem" interactions, and alkaline Bohr effects which are approximately normal. The X-ray crystallography of oxyhaemoglobin at 2·8 Å resolution shows that the residue α92 (FG4) is at the α1β2 interface[4]. Perutz and H. L.[5] have pointed out that all known haemoglobin variants with alterations at the α1β2 interface have reduced "haem-haem" interaction.

The NMR spectra of paramagnetic haem proteins indicate that the protons of the haem group are shifted by hyperfine interactions with the unpaired electrons which are delocalized from the iron[6-8]. These shifted resonances are well resolved and for the cyanide complexes of myoglobin[9] and haemoglobin (S. O., M. Fujiwara, T. Yamane and R. G. S., to be published) have been identified with specific haem protons. The positions of these resonances can be directly related to the spin densities in the porphyrin ring at the points of contact of these protons. Hence they are very sensitive to changes in the electron distribution of the haem group. Recently it has been shown by nuclear magnetic resonance (NMR) measurements on a mixed state haemoglobin consisting of methaemoglobin α and deoxyhaemoglobin β-chains that the electronic structures of the α and β-haems were the same as in the corresponding homogeneous tetramers[10]. Because this mixed state haemoglobin has a higher oxygen affinity than deoxy Hb A, it was concluded that this higher affinity was caused by changes at the interfaces between the haemoglobin subunits and not by changes at the haem.

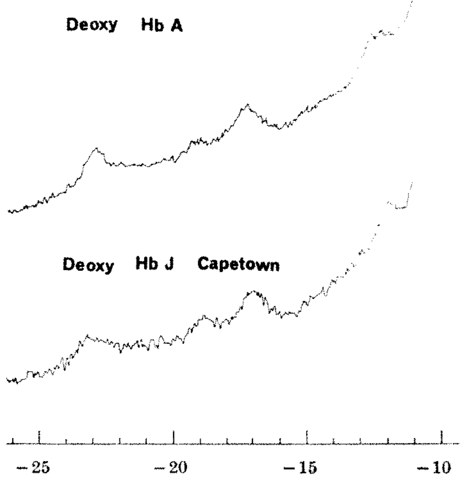

Fig. 1. Low field shifted resonances of Hb J Capetown and Hb A in the deoxy form at 20° C, *p*D 7·0.

It was already known that in the deoxy form of single Hb A chains and several high oxygen affinity haemoglobins, the Soret band of the optical absorption spectrum is broadened and shifted as compared with that of Hb A[11,12]. This correlation between optical spectrum and raised oxygen affinity was not found in Hb Chesapeake[2].

It is the purpose of the present experiment to see if the small change at the α1β2 interface in Hb J Capetown leaves the electronic structure of the haem unaltered, while reducing the "haem-haem" interaction. If these two effects can be separated, then the changes of oxygen affinity are not necessarily related to haem changes. We have therefore compared the electron distribution of Hb J Capetown and of normal Hb A before and after ligation. The separation of the two effects was observed in the previous NMR experiments on a mixed state partially ligated haemoglobin which represented a possible intermediate state of oxygenation[10], but it is desirable to carry out these experiments on two natural haemoglobins with different oxygen affinities.

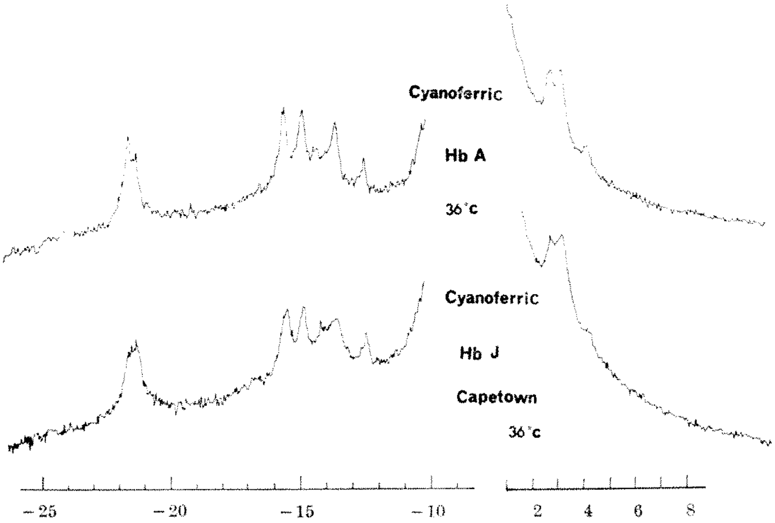

Fig. 2. Shifted resonance lines of Hb J Capetown and Hb A in the cyanoferric form at 36° C, pD 7·0

Human haemoglobin A was prepared from freshly drawn blood using the procedure of Bunn and Jandl[13]. Cyanoferric (Cyan-met) haemoglobin was obtained by oxidation of oxyhaemoglobin with 1·3 equivalents of ferricyanide in the presence of KCN and pH 7·0 phosphate buffer. Hb J Capetown was prepared from the haemolysate of a heterozygote containing 32 per cent of the Hb variant by repeated chromatography on 'DEAE Sephadex' using a pH gradient according to Huisman and Dozy[14] followed by paper electrophoresis at pH 8·9 (ref. 15) until there was no demonstrable Hb A.

The NMR spectra were measured at 220 MHz in a 'Varian *HR*-220' spectrometer. Peak positions were measured with respect to 2,2 dimethyl-2-silapentane-5-sulphonate (DSS). Low field shifts have been assigned negative signs. Because the signals were weak it was necessary to accumulate the spectra for several hours in a 1024 channel analyser.

The NMR spectra of the deoxy and cyanoferric forms of haemoglobin J Capetown and haemoglobin A are compared in Figs. 1 and 2. The spectra are the same in both forms. For deoxyhaemoglobin there are five identifiable resonances at low fields and all five in both haemoglobins have the same shifts within the experimental uncertainties of ±30 Hz. For the lowest field line, which from its measured intensity of three protons per haem is a methyl group, the total shift is more than 4,000 Hz to lower field from its position in a diamagnetic compound. Thus the fractional difference between these shifts in the two haemoglobins is less than 0·5 of 1 per cent. Slightly larger fractional values of the upper limits would be obtained from the other resonances because their total shifts are smaller.

The similarity between the Hb J Capetown spectrum and that of Hb A is established within narrower limits in the cyanoferric haemoglobins than in the deoxyhaemoglobins because the resonances in the former are narrower and more intense. Quantum mechanical considerations indicate that for the cyanoferric haem proteins the spin densities are approximately proportional to the ligand binding energy (S. O. *et al.*, to be published). On the other hand, deoxyhaemoglobin is not understood quantum mechanically, and shifts may arise from other mechanisms such as pseudocontact interaction[16]. Regardless of the mechanism, however, the shifts in deoxyhaemoglobin should be very sensitive to the electronic structure of the haem. Wyman[17] has shown that there must be an approximately 10 per cent change in the oxygen binding energy during oxygenation to account for the observed "haem-haem" interaction in normal haemoglobin. Our experiments prove that in ligated cyanoferric haemoglobin the energy difference between Hb J Capetown and Hb A is at least ten times smaller. In the deoxy form no differences were observed between the NMR spectra of the two haemoglobins. This suggests that in the unligated form also, energy differences are negligible. Thus the difference in oxygen affinity between the two haemoglobins cannot be caused by differences at the haem. Similar results in the mixed state haemoglobin could be explained by a sequential model[18] but not by the symmetric allosteric model[19]. A consequence of the sequential model is that the amino-acid change in Hb J Capetown reduces co-operation between subunits during oxygenation by affecting the binding energies at their interfaces.

Thus in the strict sense the phrase "haem-haem interaction" is a misnomer when used to describe the cooperative oxygenation of haemoglobin.

We thank M. F. Perutz and J. Greer for valuable discussions.

Exchange of Bound Tritium between DNA and Water at Different Temperatures

A CLUE to the structure of macromolecules in solution is given by the exchange of protons between the macromolecules and the surrounding solvent. We have investigated the exchange of tritium between DNA and water at different temperatures. We have used the technique

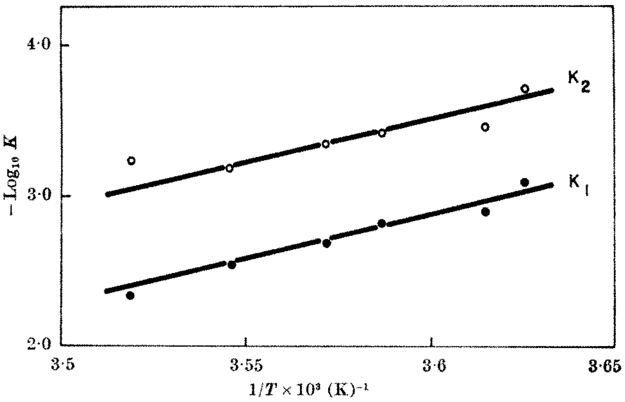

Fig. 1. Loss of ^{3}H from DNA previously equilibrated with ^3H_2O. DNA samples were equilibrated with ^3H_2O and passed through a 'Sephadex *G*-50' column to remove the ^3H_2O. The eluted DNA was incubated at the indicated temperature and at intervals samples were passed through a '*G*-25' column to separate the DNA from ^{3}H which had been exchanged. The results are presented as the residual ^{3}H bound per nucleotide pair, calculated from the specific activity of the ^3H_2O and from the amount of DNA in the DNA peak eluting from the 'Sephadex *G*-25' column (see text). The radioactivity per sample varied from 7,000 to 60 c.p.m. during the course of the exchange reaction, depending on the loss of bound ^{3}H and the yield of DNA in each sample. The solid curves were calculated as a best fit to the six sets of data using the equation

$$R = \bar{A}\ 10^{-K_1^*(T)t} + \bar{B}\ 10^{-K_2^*(T)t}$$

(see text) where $\bar{A} = 1{\cdot}962$ and $\bar{B} = 0{\cdot}410$. The fit should be compared with the experimental points.

of 'Sephadex' chromatography described by Englander[1] and used by Printz and von Hippel[2] to study tritium exchange between DNA and water.

Calf thymus DNA (Sigma) was sheared by sonication and equilibrated with ^3H_2O (500 mCi/ml.). In all experiments the concentration of thymus DNA was between 2 and 3 mg/ml. A small amount (less than 1 µg/ml.) of ^{14}C-labelled DNA from *Escherichia coli* was added as a marker. A 2 ml. aliquot of the tritiated DNA was equilibrated at the desired temperature and passed through a jacketed column (44 cm × 5 mm) of 'Sephadex *G*-50'. The emerging ^{14}C–DNA peak contained less than 1 part in 10^6 of the original ^{3}H radioactivity which could be eluted subsequently from the column. Samples from this DNA solution were passed through a second jacketed column (44 cm × 5 mm) of 'Sephadex *G*-25' to remove the free tritium. The bound tritium emerging with the ^{14}C–DNA was counted in an aqueous scintillation fluid[3].

Throughout the experiments the solvent used to equilibrate the DNA and ^3H_2O and to wash the columns was 0·1 M NaCl in 0·01 M sodium cacodylate (*p*H 7·5). The temperature of the columns and DNA solution was maintained to within ±0·2° C. The time allowed for exchange was taken as the difference between the time when the DNA solution was put on to the 'Sephadex *G*-50' column and the time when a sample emerged from the '*G*-25' column.

Fig. 1 shows the loss of ^{3}H from DNA at different temperatures. The experimental points are given as residual ^{3}H bound per nucleotide pair. Printz and von Hippel[2] observed that the loss of tritium from DNA followed a biphasic curve which corresponded to two possible tritium populations, each exchanging independently of the other. We have fitted our data with curves corresponding to the equation $R = \bar{A}\ 10^{-K_1^*(T)t} + \bar{B}\ 10^{-K_2^*(T)t}$, where R is the residual bound tritium, $\bar{A}$ and $\bar{B}$ are independent but the same for all temperatures (T), and $K_1^*(T)$ and $K_2^*(T)$ are independent constants that vary with the temperature.

The following hand computational technique has been used to find a family of functions $\bar{A}\ 10^{-K_1^*(T)t} + \bar{B}\ 10^{-K_2^*(T)t}$ to approximate f(t,T), so that $\bar{A}$ and $\bar{B}$ are independent and K_1^* and K_2^* are dependent on T. (A mathematically more sophisticated program for optimal fit by high speed computer is being prepared by R. G. Selfridge at the Computing Center, University of Florida, Gainesville.)

If $K_1^* \ll K_2^*$ the effect of K_2^* will become negligible for large t. For each T value, therefore, choose (t_1,f(t_1,T)) such that f(t_1,T) is the last datum in which the experimenter has confidence. Choose (t_2,f(t_2,T)) such that f(t_2,T) is eight or nine times greater than f(t_1,T). Solve the equations

$$\mathrm{f}(t_1,T) = A(T)\ 10^{-K_1(T)t_1}$$
$$\mathrm{f}(t_2T) = A(T)\ 10^{-K_1(T)t_2}$$

for $A(T)$ and $K(T)$ at each T. To impose the condition that $\bar{A}$ be independent of T, calculate $\bar{A}$, the arithmetic mean of the $A(T)$. Recalculate $K_1^*(T)$ for each T by solving $\mathrm{f}(t_3,T) = \bar{A}\ 10^{-K_1^*(T)_3}$ such that $t_1 \geq t_3 \geq t_2$ to give an optimal fit to the data $f(t,T)$; $t_1 \geq t \geq t_2$. Calculate $\mathrm{g}(t,T) = \mathrm{f}(t,T) - \bar{A}\ 10^{-K_1^*(T)t}$ (again choose the largest value of t, that is, t_4, for which g(t,T) has experimental validity). Choose t_5, the next to smallest t value. t_5 is not the least t, because of the possibility of contamination by another exponential $\bar{C}\ 10^{-K_3^*t}$ where $K_3^* > K_2^*$. Calculate $B(T)$ and $K_2(T)$ from $\mathrm{g}(t_4,T) = B(T)\ 10^{-K_2(T)t_4}$ and $\mathrm{g}(t_5,T) = B(T)\ 10^{-K_2(T)t_5}$. Calculate $\bar{B}$, the arithmetic mean of $B(T)$, and recalculate $K_2^*(T)$ from $\mathrm{g}(t_6,T) = \bar{B}\ 10^{-K_2^*(T)t_6}$ where $t_4 \geq t_6 \geq t_5$ and t_6 is chosen to optimize the fit to g(t,T). Then $\bar{A}\ 10^{-K_1^*(T)t} + \bar{B}\ 10^{-K_2^*(T)t}$ approximates f(t,T) with the desired properties.

Table 1. VALUES OF K_1^* AND K_2^* OBTAINED AT DIFFERENT TEMPERATURES BY FITTING THE DATA IN FIG. 1 WITH THE EQUATION $R = 1{\cdot}962 \times 10^{-K_1^*(T)t} + 0{\cdot}410 \times 10^{-K_2^*(T)t}$

T	K_1^*	K_2^*
11·2° C	$4{\cdot}6 \times 10^{-3}$	$5{\cdot}82 \times 10^{-4}$
9·0°	2·86	6·39
7·0°	2·02	4·95
5·8° C	1·51	3·92
3·6° C	1·26	3·49
2·8° C	0·818	1·98

It has been possible to fit all of the data with a value of $\bar{A}$ (1·962) and of $\bar{B}$ (0·410) both of which correspond well with the values determined previously by Printz and von Hippel[2]. Evidence for a more rapidly exchanging component can be observed at early times in the 2·8° and 3·6° samples. This component has been ignored in our analysis.

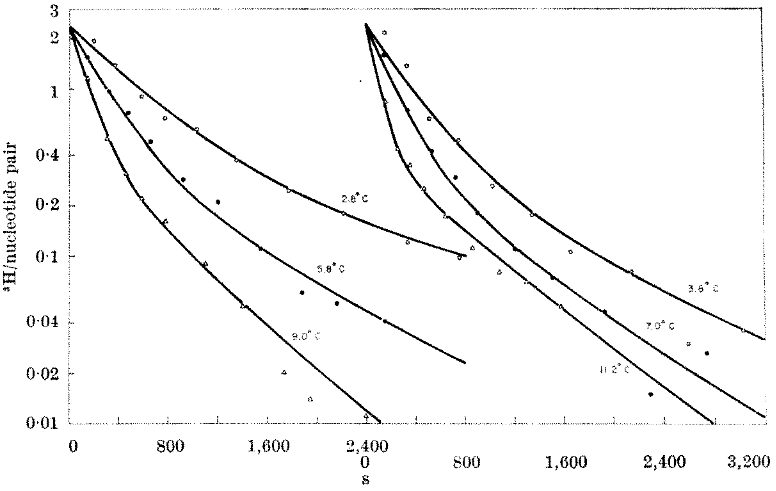

Fig. 2. A graphic representation of the data in Table 1. The slopes of the solid lines represent a Δ H$^+$ of 24 kilocalories/mole. The entropies of activation are 37·1 and 35·7 entropy units for components $\bar{A}$ and $\bar{B}$ respectively.

Table 1 lists the values of $K_1^*(T)$ and $K_2^*(T)$ obtained at the different temperatures. Fig. 2 presents the logarithm of these values as a function of $1/T$. With the exception of K_2^* (11·2°) all the values are consistent with a linear relationship between $\log_{10}K^*(T)$ and $1/T$ such that the slopes for $K_1^*(T)$ and $K_2^*(T)$ are the same. It is evident that the slope log $K_1^*(T)$ versus $1/T$ is much better defined than the slope of the same function of $K_2^*(T)$. This scatter is not unexpected if one considers that the counts at the later points of the curve are low and subject to greater error. In the following discussion we have assumed that the slopes of the two curves in Fig. 2 are the same.

From the curves in Fig. 2 we can calculate that the activation enthalpy for exchange is 24 ± 4 kilocalories/mole of activated complex and is almost the same for the fast and slow exchange components. There are about four times as many fast exchanging tritiums ($\bar{A}$) as slow ($\bar{B}$). The probability of these exchanging (entropy) is quite different: $\Delta S_1 = 37\cdot1$, $\Delta S_2 = 35\cdot7$. In the activated state, it is four times more probable for the fast component to exchange than for the slow component.

To explain these values, we suggest the following model. As proposed by Printz and von Hippel[2] the hydrogens that are exchanging are those involved in base pairing within the DNA helix. For exchange to take place, the rate limiting process would be the separation of base pairs and their subsequent orientation away from the helix centre toward the surrounding solvent. Subsequent exchange would be successful if the tritium could exchange with hydrogen bound to a solvent molecule before the bases re-orient toward the centre of the helix. This should be as probable for external tritiums as for those involved in the A·T base pair or two of those involved in the G·C base pair. The internal tritium involved in the bond between 1-nitrogens of the guanine and the cytosine groups should, however, encounter steric hindrance in exchanging with a solvent water. As a result, its exchange should occur less frequently, in spite of the similar activation energy dependence for the requirement to separate the base pair. For this difference to be observed, the probability of either a class $\bar{A}$ or class $\bar{B}$ exchange to occur during any activation event must be small—of the order of one or less exchange events per opening of the helix.

The activation enthalpy of 24 kilocalories/mole of activated complex is too high for the separation of a single base pair, and it seems more likely that the activation event involves the simultaneous separation of two or three base pairs, a thermodynamically stable situation that will preserve the stacking energy within the helix[4].

Interaction between Papova-like Virus and Paramyxovirus in Human Brain Cells: a Hypothesis

SUBACUTE sclerosing panencephalitis (SSPE), a progressive neurological disease of children, is characterized by intracytoplasmic and intranuclear inclusions in the neurones and glial cells. Although no infectious agent was isolated directly from the diseased brain tissue, a paramyxovirus, related serologically to the measles–rinderpest virus group, was recovered from SSPE brain cells maintained in tissue culture in serial passages[1]. These cultures were characterized by the formation of syncytia and by their capacity to undergo transformation[2]. Only by fusion with African green monkey kidney cells (AGMK) could an infectious syncytiogenic paramyxovirus be recovered from the brain cells.

Under the electron microscope, particles resembling paramyxovirus nucleocapsids were seen in nuclei and cell cytoplasm of all three human brain cultures[3], even though infectious paramyxovirus was recovered from only two cultures. Budding particles resembling paramyxovirus structurally were also seen in cells of the infected AGMK cultures. In addition, symmetrical particles of a different type, without membrane, were seen under electron microscope in the cell cytoplasm of one SSPE human brain culture and in AGMK cells infected with the syncytiogenic paramyxovirus isolated from the other two cultures (Table 1). In morphology and size range, particles of the second type resembled virions of the Papova virus group—for example, polyoma or SV40. These particles were observed in the cytoplasm of the human brain cell (Fig. 1*a*) and were found frequently in the same cells with paramyxovirus nucleocapsids. They were also seen in AGMK cells showing presence of paramyxovirus at the cell surface (Fig. 1*b*). In the brain of ferret injected with homogenates of infected AGMK cells (Table 1), they were seen in cells in which paramyxovirus was not observed.

ROB	+	+	NT	NT
JAC	+	−	+*	NT
LEC	+	−	+*	+ †

NT: not tested.

* African green monkey kidney cultures infected with material from heterokaryon cultures obtained by fusion of JAC brain cells with AGMK cells.

† Ferret killed two weeks after intracerebral inoculation of extracts from AGMK cells infected with material obtained from heterokaryon cultures produced by fusion of LEC brain cells with AGMK cells.

Preliminary results of gradient centrifugation of homogenates of cells showing presence of Papova-like particles revealed presence of 20S peak corresponding to the sedimentation velocity of circular DNA of the known Papova viruses[4].

Cells showing presence of Papova-like particles did not stain for either T or VP antigen in the presence of SV40 antibody conjugated with fluorescein[1].

Although particles resembling Papova virions were actually seen in cells of only one human brain culture (ROB; Table 1), intracellular particles of the same type must have been present in the two other cultures (JAC and LEC), because they were recovered, together with the paramyxovirus, in AGMK cells after fusion of the latter cells with JAC and LEC cells (Table 1).

If Papova-like virus particles are indeed present in human brain cells, then further consideration should be given to their role in the pathogenesis of chronic encephalopathies and other diseases, especially in the light of the following observations made during this study. (1) Neither tissue culture medium nor cell extracts of SSPE human brain cell cultures were infectious for normal human

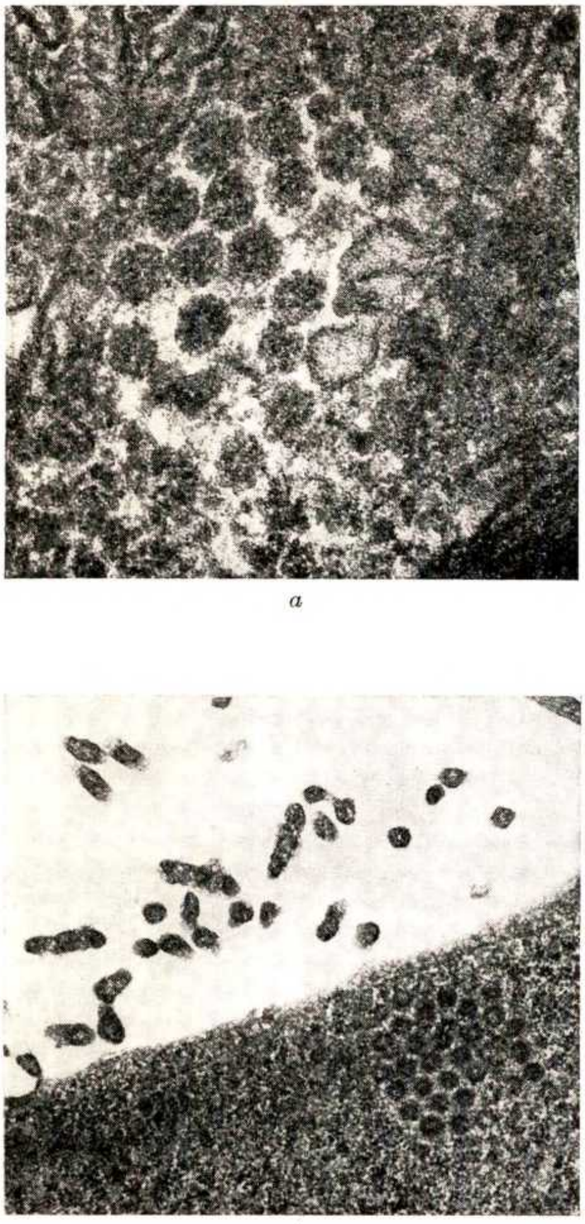

Fig. 1. *a*, Brain cell from subacute sclerosing panencephalitis patient ROB showing a cluster of Papova-like virions in the cytoplasm. cells or for cells of other animal species. Only after fusion of the human brain cells with cells of other types have particles of Papova-like virus been "rescued" together with the syncytiogenic agent[1]. (2) Papova-like virus particles in AGMK cultures were seen only in cells forming syncytia. (3) Cell-free extracts or tissue culture media from human brain cultures or from infected AGMK cultures did not produce encephalitis in ferrets, but inoculation of the same animals with viable cells from the same cultures caused encephalitis[5]. (4) Human brain cell cultures have undergone transformation[2].

We postulate that Papova-like virus particles are present as unobtrusive symbionts in human tissue, particularly brain tissue, incapable of causing signs of illness *per se*, and also unable to spread to other cells of the organism in normal physiological conditions. Cell fusion engendered by viruses belonging to the paramyxovirus group and found in cells containing the Papova-like agent enables the latter to spread from cell to cell. When a sufficient number of brain cells becomes involved in this process, the disease syndrome manifests itself.

Ferrets injected with viable AGMK cells containing both the syncytiogenic agent and the Papova-like agent developed encephalitis. Those injected with cell-free extracts from the same cultures did not, and their brain cells showed presence of Papova-like virus but not paramyxovirus particles. In addition, encephalitis was not observed in animals injected with cells infected with measles virus alone. Thus it is possible that neither a syncytiogenic paramyxovirus in the absence of the Papova-like agent nor the Papova-like agent in the absence of the syncytiogenic agent is capable of causing encephalitis.

If the Papova-like agent is "activated" by a syncytiogenic paramyxovirus, an analogy may be drawn between their interaction and that observed between syncytiogenic Sendai virus and another member of the Papova virus group, SV40. The SV40 genome can be activated[6] in transformed cells only after it spreads to other types of cells following fusion mediated by non-infectious Sendai virions adherent to the cell surfaces. The interaction between the two agents in SSPE cells may occur at the molecular level, where the DNA of the Papova virus "activates" the RNA of the paramyxovirus, or primarily at a "mechanical" level, whereby the presence of the paramyxovirus activates the fusion processes which result in the spread to other cells of the Papova virus DNA. Thus the syncytiogenic agent may represent not one virus but a group of viruses which may be encountered in man in various conditions. Acute childhood infections, such as measles, in which the brain of the patient becomes infected with the virus more frequently than has been supposed[7], may lead to SSPE if cells containing Papova-like agent become superinfected with the measles virus, thus enabling the Papova-like virus to spread from cell to cell through the mechanism of fusion. Moreover, apparent or non-apparent infections of the human organism with other paramyxoviruses which are just as capable as measles virus of fusing cells, may lead to the same disease syndrome by the same mechanism. In the first case, the syncytiogenic agent isolated from brain cells will be measles virus; in the second, it will be one of the other paramyxoviruses. The Papova-like virus, however, may be the same in both cases.

Within this context, the pathogenesis of progressive multifocal leucoencephalopathy (PML), a neurological disease in which Papova-like particles are found in abundance in brain tissue (Fig. 2), may not differ greatly from that of SSPE. PML develops almost invariably in patients suffering from other conditions such as Hodgkin's disease, leukaemia, neoplasms of various organs, sarcoidosis and others[8]. If any of these underlying conditions is accompanied by a non-apparent infection with a syncytiogenic agent such as paramyxovirus, which, after invasion of brain tissue, activates the Papova-like agent, massive concentrations of Papova-like particles[9] may result from their replication after "activation". It has not yet been possible to isolate a biologically active Papova-like agent from PML cases. This difficulty may be overcome, however, if fusion of viable cells, obtained either directly from PML brain tissue or after cultivation *in vitro*, with other cell types is accomplished in the presence of a syncytiogenic agent such as Sendai. Thus virus isolation in the case of SSPE may be duplicated in PML.

Finally, one should not overlook the fact that human brain cells containing Papova-like particles have become transformed in cultures and that the process of transformation is strikingly similar to that observed after infection of human cells with an oncogenic virus, SV40 (ref. 10). Also it should be noted that the striking hyperplasia of astrocytes in PML and SSPE resembles a neoplastic process and that interaction of two viruses similar

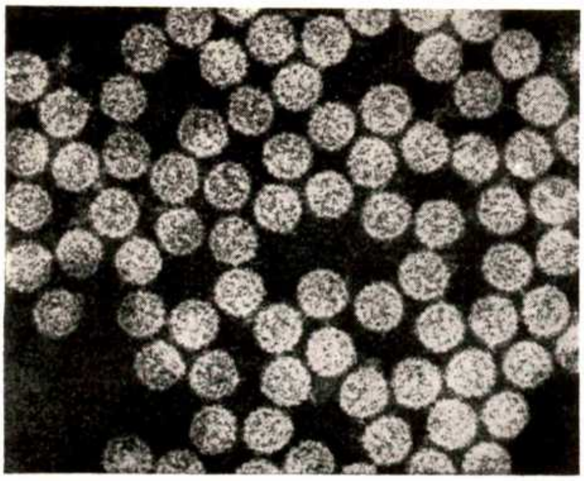

Fig. 2. Papova-like virions from brain tissue of a patient with PML. The biopsy was furnished by Dr Fusahiro Ikuta, Niigata University, Japan. Preparation kindly provided by Dr Klaus Hummeler, Children's Hospital, Philadelphia. (× 159,000.)

to that postulated for SSPE and PML may be involved in the mechanism of neoplasia.

Surface Leukaemic Antigen and Malignancy of Cells in Mice infected with Mazurenko Virus

IT is well known that virus induced mice leukaemic cells carry a specific surface antigen, which can be detected by a cytotoxicity reaction or by immunofluorescent labelling[1-3]. We have studied the time of appearance of the specific antigen in cells of various organs and tissues of mice after inoculation with a leukaemia virus, and compared this with the time when malignant transformation becomes apparent. This cellular change can be detected with the aid of histocytological examination and by the ability of such cells to grow after transplantation.

Concentrated suspensions of Mazurenko virus[4,5] were prepared by differential centrifugation[6]. Leukaemia was induced in 2 week old mice of the CC57Br strain by intraperitoneal injection of 0·2 ml. doses of these suspensions (1 ml. of virus suspension is equivalent to 1·5 mg of leukaemic tissue). Specific antileukaemia antiserum was prepared from mice which had been given a two-fold injection of a 20 per cent suspension of centrifuged virus particles and subsequently immunized five to seven times with increasing concentrations of leukaemic tissue homogenate. Before injection, leukaemic tissue was subjected to γ-irradiation at a dose equivalent to 9,600–12,000 rad.

Specific surface antigen in the cells of organs and tissues infected by the virus was demonstrated by Möller's modification of Coon's indirect method[7]. The intensity of the reaction was calculated from the index of fluorescence[8]. Values of 0·2 and higher were considered positive. Cells of thymus, lymph nodes, spleen and bone marrow were taken from three mice, and incubated with serum. The same cells incubated with serum from adult healthy animals of the same strain were used as controls. Corresponding cells from healthy mice incubated with anti-leukaemic serum were also used as controls. The specificity of the resulting fluorescence was confirmed in the fluorescence suppression experiments where leukaemic cells treated with anti-leukaemic serum were used. The same organs were examined histologically and cytologically.

Commencing on the fifth day after inoculation of the mice with virus, a suspension of spleen cells taken from three mice (prepared for the immunofluorescence reaction) was injected intraperitoneally into three 5–7 week old mice of the CC57Br strain, each animal being given four to six million cells. The recipients were kept under observation for 3·5 months. Leukaemia was diagnosed on the basis of the characteristic features of the disease.

* Proportion of recipients which developed leukaemia.

A total of 109 10–14 day old mice of strain CC57Br were infected with concentrated virus. The kinetics of appearance of specific antigens in the organs of these animals and the morphological findings and results of transplantation are presented in Table 1. Microscopic studies showed that specific surface antigens were detectable in the cells of spleen and bone marrow on the seventh day after injection of virus. From the tenth to the thirteenth day the immunofluorescence reaction was positive only for the spleen cells. Commencing on the twelfth day, however, the index of fluorescence for the lymph nodes, thymus and bone marrow approached significant levels. Surface antigen was clearly detected in all organs studied from the fifteenth day onwards, the index of fluorescence gradually increasing subsequently.

Increased numbers of poorly differentiated cells were detected by histological examination of the spleen and lymph nodes commencing on the fourteenth day. They were usually present in the wide centres of multiplication, in the follicles, and also in the form of separate small foci in the splenic pulp. From the twenty-second day of the investigation, marked disorganization of normal spleen and lymph node structure took place, on account of diffuse or large focal hyperplasia of reticular or homocytoblastic cells. A similar disorganization was noted in the thymus. Bone marrow retained its content of polymorphonuclear cells at all times. It was only from the twenty-second day after infection with virus that small solitary centres of leukaemic cells were observed.

Focal growth of reticular cells was observed around lymphoid follicles and in the red pulp of spleen as well as in the bone marrow as early as the fourth day after infection. In the liver and kidneys, degenerative changes of parenchymal cells, micronecrosis and haemorrhages were found. Large numbers of histiocytes, fibrocytes and reticulocytes were usually observed in the spleen, the liver and the kidneys. The appearance of a large number of monocytes in the peripheral blood was also characteristic. Such evidence for an active reticuloendothelial system continued up to the twenty-second day after injection of virus, by which time leukaemic symptoms were fully developed. Transplantations of cells were positive from the eighteenth day after the injection of virus: leukaemia developed in recipient mice within 4–5 weeks.

Clearly, the appearance of specific leukaemic antigen in animals infected with virus precedes the malignant transformation of normal cells into ones that are leukaemic, according to morphological studies and their capacity for survival after transplantation. The nature of the specific surface antigen detected by immunofluorescence studies in leukaemia is still unclear. If an analogy is drawn with studies of DNA-containing viruses, the appearance of the specific surface antigen may be connected with changes in the cell surface in the process of leukaemogenesis. Our findings would then agree with those of other authors who, using the immunofluorescence test, detected the appearance of specific surface antigen before the morphological transformation of cells in tissue culture inoculated with SV40 virus and polyoma virus[9,10]. Specific fluorescence in these experiments is connected only with the formation of new cellular surface antigen and is not conditioned by the virus itself or by antigen present in the virus particles. In our experiments we have not attempted to differentiate cellular antigen from the antigen of virus particles, because in mouse leukaemia caused by RNA-containing virus the viruses are situated on the surface of cells in the tissues and organs of virus-inoculated animals. Apparently, the specific fluorescence on the surface of the cells we have studied is to be attributed to the appearance of new cellular antigen and to viral antigen.

Leucine Naphthylamide: an Appropriate Substrate for the Histochemical Detection of Cathepsins B and B'

Sylvén and Snellman[1] have reported that highly purified beef spleen cathepsin B catalyses the hydrolysis of both benzoylarginine β-naphthylamide (*p*H 6·0 optimum) and leucine β-naphthylamide (*p*H 7·3 optimum). The latter effect was termed "leucine naphthylamidase" activity. Action on both substrates was attributed to a single enzyme, namely, cathepsin B. Maximal rates of hydrolysis were obtained only when cysteine and EDTA were included in the reaction mixtures, a finding that is consistent with the needs of cathepsin B (ref. 2).

Recently, we have obtained contrary evidence: we find that benzoylarginine β-naphthylamide and leucine β-naphthylamide are hydrolysed by different enzymes, and that neither of these is cathepsin B. We feel compelled to present this evidence because Sylvén and his associates[3], as well as others[4], are using leucine β-naphthylamide in a histochemical procedure based on the leucine naphthylamidase effect for observing enlarged lysosomes such as autophagic vacuoles. They recommend this technique for the early detection of cellular injury and the onset of regression and support the validity of the method by their substrate specificity studies[1]. Our data suggest, however, that those studies were conducted with a partially purified preparation of lysosomal cathepsin B′ that was contaminated with an aminopeptidase. There are indications that the latter may have been a sulphydryl-dependent, puromycin-sensitive aminopeptidase like that described by Ellis and Perry[5,6].

First of all, we have confirmed the findings of Otto[7], namely, that gel filtration can be used (Fig. 1) to isolate a second trypsin-like enzyme, called cathepsin B′, from cathepsin B preparations made according to Greenbaum and Fruton[2]. Although Otto demonstrated that cathepsins B and B′ are both sulphydryl-dependent enzymes that hydrolyse benzoylarginine amide at acid *p*H, these activities were readily distinguished by the fact that only cathepsin B′ hydrolysed benzoylarginine *p*-nitroanilide. We observe (Fig. 1) that cathepsin B′ also hydrolyses benzoylarginine β-naphthylamide, while the classical cathepsin B attacks only benzoylarginine amide. This, of course, has implications for the use of benzoylarginine β-naphthylamide as a histochemical substrate for the classical cathepsin B. Any confusion regarding the subcellular localization of cathepsins B and B′ may not prove to be serious because both were found by Otto and Schepers[8] in lysosome-rich fractions prepared from rat liver by the method of Sawant *et al.*[9].

We prepared cathepsins B and B′ from bovine spleen by a modified version of Otto's procedure, the basis of which was developed by Greenbaum and Fruton[2]. Acid

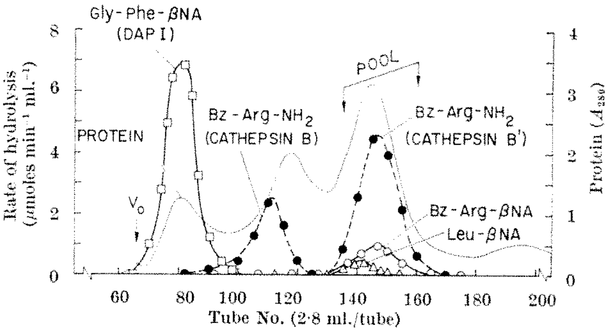

Fig. 1. Gel filtration of the ammonium sulphate fraction of beef spleen on 'Sephadex *G*-100' column (3·2 × 94 cm) equilibrated with 4 mM 2-mercaptoethanol–0·5 mM EDTA–0·1 M acetate buffer (*p*H 4·2) at 5° C. 580 mg of protein was applied in 5 ml. of column buffer; the flow rate was maintained at 19·5 ml. per h; 2·8 ml. fractions were collected. V_0 designates the void volume of the column. βNA = β-naphthylamide group; Bz = benzoyl group; DAP I = dipeptidyl aminopeptidase (cathepsin C).

extraction of 1 kg of fresh bovine spleen for 22 h at *p*H 3·5 and 37° C was followed by the recovery from the extract of the protein precipitated with ammonium sulphate between 40 and 70 per cent of saturation. The next step (passage through 'IRC-50' resin) was by-passed. The specific activity gain that was accomplished by performing the acid extraction at 37° C, rather than at 3° C, compensated to a large extent for the omission of the resin treatment. Gel filtration on 'Sephadex *G*-100', Otto's fourth and final step, was then performed instead of the final step used by Greenbaum and Fruton[2] (ethanol precipitation of the mercury derivative of cathepsin B). In this way Otto's cathepsin B′ remains, preferentially, in the supernatant.

Dipeptidyl aminopeptidase I (cathepsin C) was readily eliminated: it emerged from 'Sephadex *G*-100' only slightly retarded (Fig. 1). Confirming the results of Otto[7], we found that cathepsin B emerged before cathepsin B′. It seemed particularly significant, in view of the findings of Sylvén and Snellman[1], that the cathepsin B′ peak contained leucine naphthylamidase activity. It is obvious from Fig. 1 that leucine naphthylamidase tends to be closely associated with cathepsin B′, and this may help to explain why Sylvén and Snellman found "leucine naphthylamidase" activity in their preparation, which was also a 'Sephadex *G*-100' fraction. The results in Fig. 1 show that only cathepsin B′ hydrolyses benzoylarginine β-naphthylamide, so that the "cathepsin B" preparation of Sylvén and Snellman[1], purified as recently described by Snellman[10], must have been an enriched preparation of cathepsin B′. Considering the molecular weight of cathepsin B (about 50,000, ref. 7), one would expect cathepsin B to be present in Snellman's cathepsin D fraction.

Assays on benzoylarginine amide were conducted according to Greenbaum and Fruton[2] for cathepsin B. The methods of ammonia diffusion and quantitation are described elsewhere[11]. Rates of naphthylamide hydrolysis were determined at 37° C by a direct, recording fluorometric method[12]. Benzoylarginine β-naphthylamide (0·2 mM) was incorporated into reaction mixtures containing 4 mM cysteine–9 mM EDTA–17 mM phosphate buffer (*p*H 6·0). Dipeptidyl aminopeptidase I (cathepsin C) was assayed fluorometrically on glycylphenylalanine-β-naphthylamide[11]. Leucine β-naphthylamide was assayed by the method of Ellis and Perry[6]. The enzyme solution (0·1 ml.) was combined with 2·9 ml. of 5 mM 2-mercaptoethanol–0·15 M Tris–HCl buffer (*p*H 7·3), and preincubated 5 min at 37° C before adding 1·0 ml. of 0·8 mM leucine β-naphthylamide at 37° C; the final volume was 4 ml.

Subsequently (Fig. 2), the leucine naphthylamidase and cathepsin B′ activities were completely separated by subjecting the 'Sephadex' fraction to gradient elution chromatography on DEAE-cellulose. In designing our purification procedure it was necessary to consider only specific activity, and we were able to generate a preparation of cathepsin B′ having a specific activity comparable with that of Otto[7]. Otto did not use benzoylarginine β-naphthylamide, so we could only compare activities measured on the amide. The bovine spleen leucine naphthylamidase isolated in Fig. 2 had many properties in common with the puromycin-sensitive, sulphydryl-dependent aminopeptidase first demonstrated in the soluble fraction (cell sap) of bovine pituitary glands by Ellis and his associates[5,6]. It was strongly inhibited by puromycin, displayed a preference for the arylamide derivatives of basic amino-acids (see Fig. 2) and a sulphydryl requirement, and had a *p*H optimum of about 7·3. The latter three characteristics were reportedly exhibited by the beef spleen "leucine naphthylamidase" activity that Sylvén and Snellman[1] and Snellman[10] attributed to cathepsin B. Related studies by Barrett and Poole[13] have shown that the leucine naphthylamidase activity contained in human rheumatoid synovium can be inhibited by puromycin, both in crude extracts and at the histochemical level. They also reported that the cathepsin B activity contained in crude synovium extracts, assayed on benzoylarginine amide, was unaffected by puromycin.

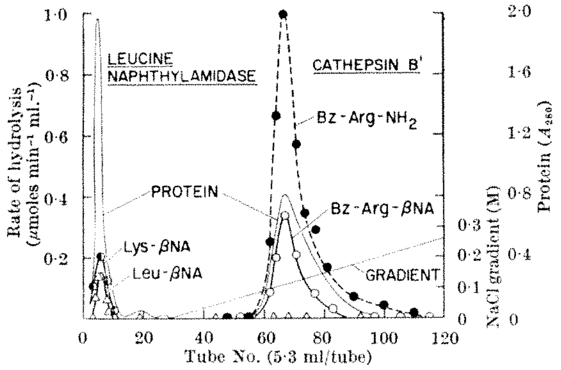

Fig. 2. Separation of beef spleen leucine naphthylamidase from cathepsin B′ by gradient elution chromatography (of the 'Sephadex *G*-100' fraction) on a microcrystalline DEAE-cellulose (Whatman 'DE-52') column (1·3 × 23 cm) equilibrated with 0·01 M sodium phosphate buffer–4 mM 2-mercaptoethanol (*p*H 7·1) at 5° C. 70 mg of protein was applied in 4·7 ml. of column buffer. A linear NaCl gradient was generated using a limiting buffer of 0·01 M phosphate–1·0 M NaCl–4 mM 2-mercaptoethanol (*p*H 7·1); flow rate was 24 ml. per h; 5·3 ml. fractions were collected.

Because leucine naphthylamidase activity is obviously distinct from cathepsin B′, and possibly arises from the cell sap, we have wondered how Niemi and Sylvén[3] have apparently been able to use a leucine naphthylamidase histochemical reaction to visualize autophagic vacuoles. It should be noted that their sections have to be incubated at *p*H 5·5 in order to obtain localization of reaction product by simultaneous coupling with a diazonium salt. Because the *p*H optimum of the leucine napthhylamidase reaction is 7·3 (ref. 1), we suspect—as one possibility—that the reaction product formed at *p*H 5·5 appears slowly enough to allow time for the lysosomes to scavenge and concentrate the dye, a property of lysosomes that seems to be extremely significant[14,15]. Niemi and Sylvén[3] did report that between *p*H 6·0 and 7·0 a generalized cytoplasmic staining occurred that obscured lysosomal structures, but they attributed this reaction to separate cytoplasmic aminopeptidases[12] and related the *p*H 5·5 reaction to cathepsin B.

Regardless of whether any leucine naphthylamidase activity resides within lysosomal structures, our results demonstrate: (*a*) that this activity is distinct from cathepsins B and B′, and (*b*) that only cathepsin B′ acts on benzoylarginine β-naphthylamide.

Histochemistry of some Lysosomal "Proteolytic" Enzymes of Human Rheumatoid Synovia

ONE subcellular manifestation of rheumatoid arthritis is that the membranes of the lysosomes in the synovial lining cells are virtually functionless; by contrast, in non-rheumatoid synovia—even after recent mechanical trauma—the lysosomal membranes in the lining cells are functional in that they retard entry of the substrates used for the demonstration of the intra-lysosomal enzymes[1]. Barrett and Poole[2], while not disputing this conclusion, questioned the precise nature of the lysosomal enzyme used in the study, which was visualized and measured microdensitometrically on the basis of the hydrolysis of leucine-2-naphthylamide, the liberated naphthylamine being trapped by 'Fast Blue B' (tetra-azotized dianisidine) to form an insoluble dye. By precise biochemical analysis, they demonstrated that human synovial tissue, taken from rheumatoid joints, contained cathepsins B and D as well as aminopeptidase activity. They showed that cathepsin D cannot hydrolyse leucine-2-naphthylamide and quoted unpublished data from other workers which suggested that cathepsin B could not hydrolyse this substrate. From this evidence they concluded that the particulate enzyme activity which was demonstrated by this substrate was a lysosomal aminopeptidase.

The recent detailed work of Snellman[3] showed that highly purified and electrophoretically discrete cathepsin B does, in fact, hydrolyse this substrate. But Barrett and Poole also claimed that the specific nature of this lysosomal enzyme could be elucidated because, although puromycin is a powerful inhibitor of aminopeptidases, it has much less effect on cathepsins B and D. Their results with 'Hyamine 1622' were less valuable because we find that this compound interferes with the naphthylamine–'Fast Blue' reaction and produces spurious histochemical effects.

Synovial tissue, especially that taken from rheumatoid joints, contains a large number of different cell types. Attention was previously focused[1] only on the synovial lining cells which, it was argued, might be significantly involved in the erosion of the articular cartilage. These cells probably correspond to the electron microscopists' type A and B cells[4–6] or to the "synovial membrane" in the looser terminology. Even when the surgeon is specifically attempting to sample these linings, they are frequently absent in the biopsy. Barrett and Poole's photographs of their histochemical "leucine naphthylamidase" reaction, which was largely inhibited by puromycin, depict cells which resemble fibroblasts or macrophages of the type which occur at a depth not less than ten cells below the synovial surface.

Rheumatoid synovia were chilled in hexane at –70° C, sectioned with a cooled knife in a cryostat at –30° C, and tested with leucine-2-naphthylamine and tetra-azotized dianisidine (Serva) by methods[7] very similar to those used by Barrett and Poole. Serial sections were incubated in the same medium to which 1×10^{-3} M puromycin (Nutritional Biochemicals) had been added. The amount of enzyme activity was measured by means of a scanning and integrating microdensitometer; the reaction time was kept to 15 min, at which time the response of the tissue, and of the instrument, was linear with activity[8]. With this instrument the cell type can be determined by visual microscopy and the activity of the selected cell, or group of two cells, can be measured. All measurements, whether of synovial cells or those of the deeper layers, were made with the same apertures, to ensure the same projected area of the tissue on to the photo-multiplier. Consequently, the measurements are of activity per unit area of section and are directly comparable. Tests were also made for non-specific absorption, caused by the scattering of light; this was found to be negligible in these sections which were mounted in Farrant's medium. Measurements were made of as many fields (of two cells each) as possible in the synovial lining, and of a sufficient number of deeper cells to yield a meaningful mean value. The reactions with and without puromycin were performed at the same time and the measurements were made within a day of the reactions, to avoid errors as a result of the fading of the dye produced, especially if the sections are not kept in the dark. The results obtained with rheumatoid synovia from the knees of two patients were plotted as population histograms (Figs. 1*A* and *B*) and the mean activities were calculated (Table 1). In agreement with Barrett and Poole, we find that puromycin strongly inhibited the reaction in the deeper cells. Inspection of the sections indicated that this inhibition varied

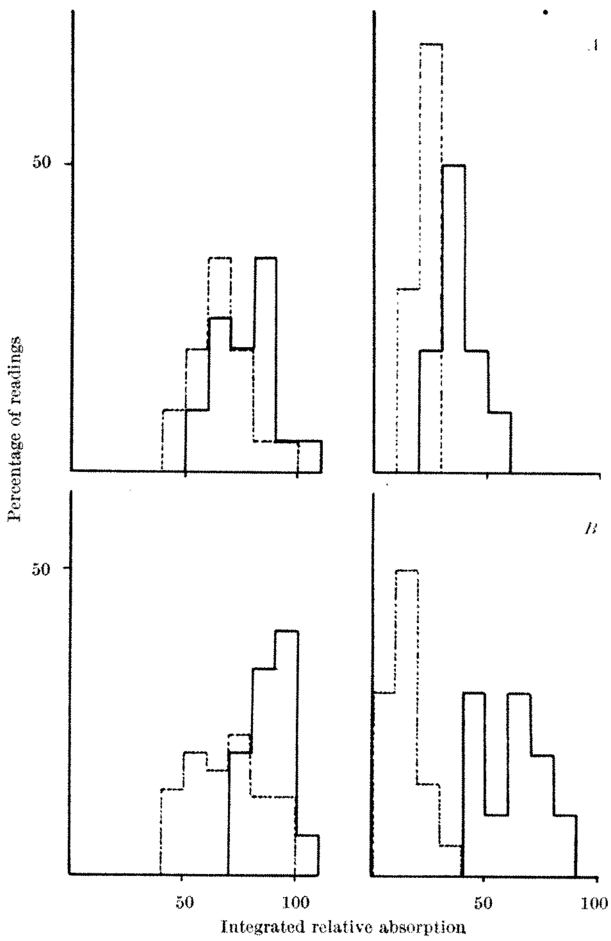

Fig. 1. Population histograms of the measurement of "leucine naphthylamidase" activity ("integrated relative absorption" measured by scanning and integrating microdensitometry). ———, Activity; - - - -, activity of the same region of the tissue when tested in the presence of puromycin. *A*, Activity measured in the synovial surface cells and in cells about ten cells below the surface; *B*, activity measured in the surface cells and in cells about twenty cells below the surface.

Table 1. MEAN ACTIVITY* OF "LEUCINE NAPHTHYLAMIDASE" AND THE EFFECT OF PUROMYCIN

	Without puromycin		With puromycin		
	Activity	No. of readings	Activity	No. of readings	Inhibition (per cent)
Case 1					
Synovial lining cells	76·2	(20)	66·1	(20)	13·3
Deeper cells	37·5	(10)	19·8	(10)	47·2
Case 2					
Synovial lining cells	88·7	(15)	69·0	(30)	22·2
Deeper cells	60·0	(10)	14·0	(20)	76·7

* Integrated relative absorption, in arbitrary units. A relative absorption of 50 units corresponds to a completely homogeneous field of absolute extinction value of 0·34. The relation between relative absorption and extinction is linear.

slightly at different levels below the synovial surface. Quantitatively it was found that puromycin caused between 47 and 77 per cent inhibition in these cells (Table 1), the inhibition being greater in the deeper cells. The scatter of the readings is shown in Fig. 1. But in marked contrast, puromycin had much less effect on this enzymatic reaction in the synovial lining cells (13 and 22 per cent inhibition).

The enzyme activity in the deeper cells might be attributable solely to leucine naphthylamidase because 1 mM puromycin can inhibit 89 per cent of the activity of purified leucine naphthylamidase[2], although apparently it is less effective in tissue sections[2]. The relatively slight inhibition produced by puromycin in the synovial lining cells might indicate that all this activity represents cathepsin B; or that about 20 per cent of the total "leucine naphthylamidase" activity in these cells represents true aminopeptidase activity and up to 80 per cent cathepsin B. Either way, the use of puromycin indicates that synovial lining cells contain a high proportion of apparently catheptic activity, whereas the cells of the deeper layers contain predominantly aminopeptidase activity.

We thank the Medical Research Council for a grant for this work, the Arthritis and Rheumatism Council for their support, and Mr J. C. R. Hindenach of the West London Hospital for his help in obtaining surgical specimens.

Morphogenetic Substratum for Differentiation of Cartilage in Tissue Culture

WE report here a new system for studying the development of cartilage from post foetal mesenchymal cells *in vitro*. The chondrocytes develop under the influence of the matrix pattern of a substratum prepared from decalcified bone. In this system, a chemically defined medium is introduced and embryo extracts are avoided in order to exclude all the soluble or particulate material that may be present in cultures of skeletal tissue[1–5].

Fifty samples of minced muscle, approximately 2 mm^3, were excised from the thigh muscles of newborn Sprague–Dawley rats and immediately transferred to plastic flasks 'T-30' (Falcon Plastics) or organ culture dishes (Falcon) containing 5·0 ml. and 1·0 ml. of 'medium 199' (Gibco). Care was taken to exclude muscle origins and insertions. Foetal calf serum (Hyland Laboratories) was added in sufficient quantities to produce a final protein concentration of 15–20 per cent. The samples were washed in Ca^{2+} and Mg^{2+} free Tris buffer three times to remove old blood. Flasks and dishes were placed in a water jacketed incubator at 37° C with a gaseous phase of 5 per cent CO_2 in air, and changed every other day, for periods of 10 to 36 days. The tissue was exposed to the nutrient media and fragments were cultured in five different ways: directly on plastic; directly on plastic with media covered with a thin layer of mineral oil; on wire grid; packed loosely into the medulla of a segment of lyophilized cortical bone matrix decalcified with 0·6 M HCl[6–8]; packed into similar segments of cortical bone matrix after denaturation with acid–ethanol, decalcification and lyophilization[8]. At 5 day intervals all cultures were fixed in formalin for histological sections and stained in haematoxylin–eosin and azure II.

Free fragments of explanted muscle led to a profuse outgrowth of amoeboid and spindle shaped mesenchymal cells. The new cells grew out within a few days, and the population density increased until a monolayer covered the bottom of a plastic flask measuring 25 cm^2. The monolayer pattern of cell growth was modified in seven of the twenty cultures of muscle that were placed in the interior of a cylinder of HCl decalcified diaphyseal adult rat bone matrix: in these, the mesenchymal cells migrated from the muscle tissue interstices but also reaggregated and differentiated into hyaline cartilage. Cells, after proliferating along the surface of the bone matrix, produced small nodules of cartilage in the space between the old matrix and muscle—or on the surface of the old matrix—but never inside a fragment of muscle. A greater percentage of cultures producing cartilage might have been obtained with natural media, but this meant introduction of too many undefined substances. A mass of cartilage developed (Fig. 1) from young mesenchymal cells proliferating on the surface of the decalcified bone matrix when the culture was confined to a chemically defined medium. The intimate relationship between new growth and old matrix is illustrated (Fig. 2). Cartilage was formed only from that part of the cell population in close contact with the old matrix. The old bone matrix collagen was not resorbed by cells cultured in 'medium 199'. In the same medium, control cultures, in which the explants of muscle were packed into the medullary cavities of segments of bone matrix denatured with acid–ethanol, produced an outgrowth. There was no clonal aggregation or differentiation of cartilage cells, however.

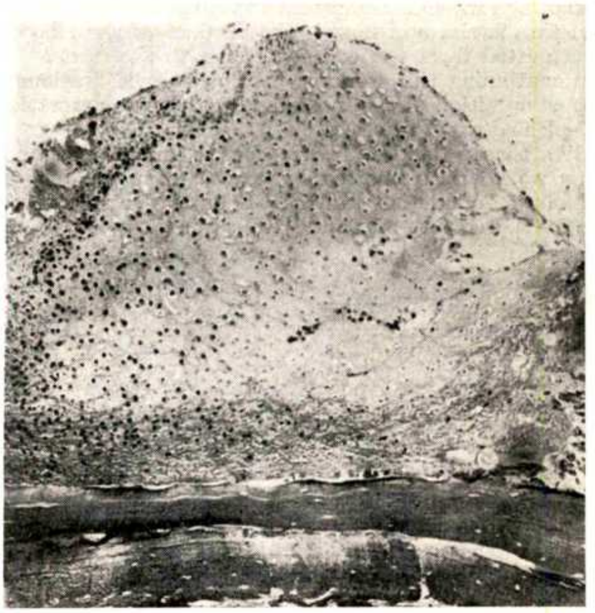

Fig. 1. Photomicrograph showing new proliferation and differentiation of cartilage (above) on a substratum (below) of rat bone matrix prepared by decalcification in 0·6 M HCl at 2° C for 96 h.

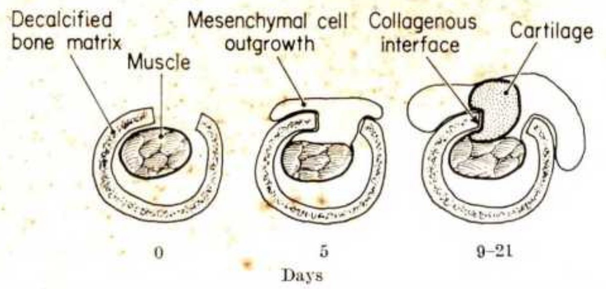

Fig. 2. Diagrammatic representation of the sequence of events leading to differentiation of cartilage from mesenchymal cells under the control of a substratum of decalcified native bone matrix. The substratum dissuades a segment of the population from monolayer formation, enhances cell aggregation and promotes cartilage cell differentiation.

These observations demonstrate that post foetal mesenchymal cells differentiate into cartilage in response to a complex set of conditions. One possible set of conditions would be a particular mixture of CO_2 and O_2, which exists in the interior of a segment of diaphyseal cortical bone. Another would be a morphogenetic substratum provided by undenatured decalcified bone matrix. Evidence for the first set comes from experiments on explants of differentiated skeletal tissues including cartilage[2]. Evidence for the second set comes from recent experiments on implants of morphogenetic matrices prepared from bone and other calcified tissues[6-8]. The highly stable acid insoluble matrix of calcified tissues is a morphogenetic, firmly cross-linked pattern which is imposed on a young mesenchymal cell population by some presently unknown mechanism.

Physico-chemical conditions in tissue culture activate a mesenchymal cell biosynthetic mechanism characteristic of a species. They do not stimulate a new biosynthetic pathway[1,5,9]. In an enriched medium under mineral oil, somite cells differentiate into cartilage at an earlier stage of development than in an unenriched medium[10]. In our system, no enrichment of the medium and only contact between cells and surface of undenatured bone matrix is sufficient to switch the pathway of development of mesenchyma from fibrous tissue to cartilage. Various concepts for cell differentiation[11-15] have been proposed and constitute valid interpretations. The questions are, what is the nature of the receptor in a mesenchymal cell population which is competent to respond to the morphogenetic matrix, and how is the product of the response transmitted from one cell generation to the next? We are continuing this work with stepwise modifications in the composition of the media and with new preparations of calcified tissue matrices.

We thank Sandra Harris for technical assistance. This work was supported by grants from the John A. Hartford Foundation and the US Public Health Service, National Institute of Dental Research.

Uniquely Oriented Epidermal Lipid

AN important function of the stratum corneum of skin is to limit the penetration of substances[1]. This is dependent on a lipid-protein complex which can be disrupted by a variety of polar organic solvents[2], and diffusion studies suggest that filamentous protein and certain polar lipids are involved[3]. We describe here a lipid which has a characteristic orientation with respect to the long axis of the keratin filaments and which may be an important component of the lipid-protein complex.

X-ray diffraction studies of mammalian stratum corneum have shown the keratin filaments to be randomly arranged in planes parallel to the skin surface[4], but after stretching the tissue an oriented α-protein pattern can be seen with meridional arcs at 5·14 Å and equatorial arcs at 9·8 Å. In addition to the usual keratin reflexion, meridional arcs were seen at 4·15 Å in the α-type epidermis of mammals, amphibians, birds and reptiles (Fig. 1*a*). The 4·15 Å spacing was absent from hair, nails and feather-type tissue of birds and reptiles.

The subcellular localization of the material giving rise to the 4·15 Å spacing was studied by differential centrifugation of isotonic sucrose homogenates of trypsin or heat separated epidermis. The 4·15 Å spacing was observed in the 1,000*g* precipitate and not in the 1,000*g* supernatant. The 1,000*g* precipitate was then extracted with 6 M urea in the presence of a 0·1 M mercaptoethanol at *p*H 10·5[5]. The solution was dialysed, lyophilized, and fibres were drawn from the isolated protein. These isolated keratin fibres showed, in addition to the 9·8 Å and 5·14 Å keratin reflexions, a 4·15 Å reflexion on the meridian. The results strongly suggest that the material producing the 4·15 Å spacing is closely related to the keratin filaments and does not arise from some other part of the cell. Extraction of pulverized stratum corneum with hexane or hot water failed to remove the 4·15 Å arcs, but treatment with chloroform–methanol (3 : 1) abolished them. The X-ray diffraction pattern of material extracted with chloroform–methanol showed a complete circle at 4·15 Å (Fig. 1*b*) instead of arcs, suggesting that the orientation observed in intact epidermis arises from the spatial relationship between the keratin filaments and the lipid producing the 4·15 Å spacing. A 4·15 Å spacing was not observed in X-ray diffraction patterns of material isolated with chloroform–methanol from subcutaneous fat, liver or cerumen. Chloroform–methanol extracts from stratum corneum were purified further by chromatography on silica-gel in a solvent of 85 per cent

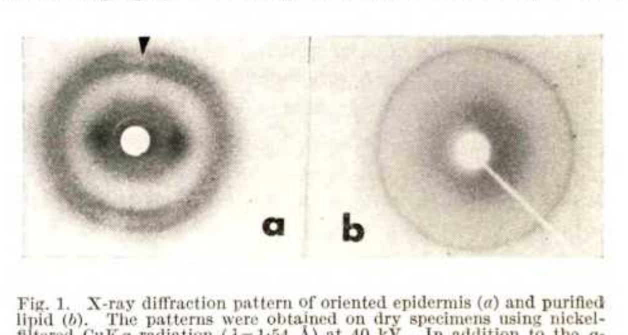

Fig. 1. X-ray diffraction pattern of oriented epidermis (*a*) and purified lipid (*b*). The patterns were obtained on dry specimens using nickel-filtered CuKα radiation ($\lambda = 1{\cdot}54$ Å) at 40 kV. In addition to the α-pattern, the epidermis shows a reflexion at 4·15 Å accentuated on the meridian.

benzene and 15 per cent methanol. The component which was used for the subsequent analyses had an approximate R_f of 0·55 in the benzene–methanol system. The isolated material had characteristic wide and low angle X-ray diffraction patterns with reflexions at 4·15 Å, 42·5 Å, 49·6 Å and 134·0 Å. Spacings of approximately 4·15 Å are sometimes associated with lecithin–cholesterol–water complexes[6], but melting and drying failed to alter the X-ray pattern, negating such a hypothetical complex as the cause of the 4·15 Å spacing. Treatment of the material with acid and alkali failed to change its X-ray diffraction pattern, suggesting that it is not a fatty acid or fatty acid salt.

Mass spectrometric analysis revealed a compound with $m/e^+ = 284$ and a disintegration suggestive of a long chain aliphatic compound. Such a relatively polar non-saponifiable lipid could have a wide angle X-ray diffraction pattern with a 4·15 Å spacing, representing the distance between adjacent hydrocarbon chains. To obtain X-ray diffraction patterns with 4·15 Å arcs parallel to the 5·14 Å reflexions of keratin, the long axis of the lipid molecule would have to be perpendicular to the axis of the keratin filament. Fraser *et al.* found a similar orientation of a lipid in an α-keratin[7].

Although the lipid has not been specifically identified, its physical properties do not correspond with any of the well described lipids known to be present in the epidermis. Further characterization may make it possible to relate the structure of the protein–lipid complex to the properties of epidermis.

We thank Dr James Orr for his work on mass spectrometric analysis. The work was supported by grants from the US National Institutes of Health.

Myosin Filaments in Vertebrate Smooth Muscle

THE sliding filament mechanism for muscular contraction was first established in the case of vertebrate striated muscle[1,2]. Shortly afterwards good evidence for the existence of a similar mechanism was obtained in a molluscan smooth muscle[3]. Attempts to explain contraction in vertebrate smooth muscle, however, met with considerable difficulties, mainly because of uncertainty about the state of myosin in the living relaxed muscle. This still cannot be decided from the biochemical[4–6], electron optical[7–16] and X-ray diffraction[17–19] evidence available so far. Here we present evidence from X-ray diffraction studies suggesting that in living relaxed vertebrate smooth muscle myosin is present in the form of filaments.

We have used low angle X-ray diffraction techniques to study the taenia coli muscle of the guinea-pig in the living relaxed state as well as during spontaneous rhythmic contractile activity. The muscle was dissected and maintained in a circulated Ringer solution of a composition given by Bülbring and Golenhofer[20]. A mixture of 97 per cent O_2 and 3 per cent CO_2 was bubbled through this Ringer solution. For examination in the X-ray beam the muscle was mounted in a 'Perspex' cell between windows of polyester film. To monitor the state of the muscle, connexion was made to either isometric or isotonic recording devices. After mounting in the cell, the muscle was allowed to equilibrate to a constant length or tension over a period of hours before the X-ray exposure, the aim being to obtain well-oriented specimens.

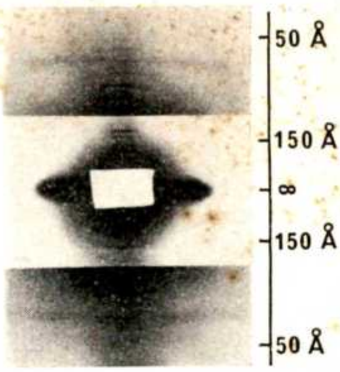

Fig. 1. Low angle X-ray diffraction pattern from a living relaxed taenia coli muscle holding a 20 g weight at 15° C. Specimen-to-film distance 36 cm. × 2. Fibre axis vertical. Centre of print underexposed to show: (*a*) broad reflexion on equator near 120 Å (actin lattice); (*b*) strong meridional 130 Å (collagen, fifth order of 650 Å); (*c*) weaker meridional 144 Å (myosin). Outer part of print shows higher order meridionals from collagen, and diffuse layer lines near 59 Å and 51 Å from actin.

The X-ray cameras were of the mirror–monochromator type described by Huxley and Brown[21], with a specimen-to-film distance of about 36 cm. A quartz crystal was used to focus the CuKα_1 radiation ($\lambda = 1·5405$ Å) from an Elliott-Automation rotating anode generator, operated at 750 W with a nominal focal size of 1 × 0·1 mm. With this combination of focal size and specimen-to-film distance, the resolution between orders was about 3000 Å. Exposure times varied between 2 and 24 h depending on the region of the pattern examined.

Our experiments with the living relaxed muscle, maintained at 12°–15° C, have confirmed all the previously described features of the low angle diffraction pattern, including meridional reflexions from collagen at orders of an approximately 650 Å repeat, layer lines from actin in the region from 59 Å out to higher angles, and a equatorial reflexion from actin filament lateral organization at a spacing of 110–120 Å (refs. 17–19, 22). We also observed a meridional reflexion at 144 ± 1 Å, and two diffuse layer lines at axial spacings of about 200 Å and 400 Å. Here we propose to deal only with the 144 Å reflexion.

In patterns from living relaxed muscles (Fig. 1) we find that the ratio of peak intensities of the 144 Å reflexion and of the adjacent fifth order collagen reflexion at about 130 Å usually lies between 1 : 2 and 1 : 1. Patterns from muscles in a Ringer solution containing 0·1 per cent phosphotungstic acid show enhancement of the diffracted intensity from collagen; the above-mentioned ratio comes to at least 1 : 10.

Spontaneous rhythmic contractions can be induced in the muscle by raising the temperature of the Ringer solution to about 37° C. Patterns obtained during such activity show a very marked decrease in the intensity of the 144 Å reflexion. By contrast, the actin layer lines from 59 Å outwards and the "400" Å layer line become clearer. The 120 Å is less sampled. No appreciable changes are seen in the collagen pattern. On lowering the temperature to about 12°–15° C, the whole diffraction pattern very nearly returns to that characteristic of resting muscle.

We consider that the 144 Å meridional reflexion arises from the structure of myosin filaments, and (as in vertebrate[21] and insect[23,24] striated muscles) at least in part represents the axial periodicity of heavy meromyosin projections. The size of the myosin filaments in vertebrate smooth muscle is difficult to estimate, because from the width of the 144 Å reflexion (in a direction perpendicular to the fibre axis), it seems that the coherently diffracting region is larger in cross-section than can reasonably be supposed to be the diameter of a single myosin filament. We are investigating the nature of this filament organization, details of the actin structure, the origin of the "400" Å layer line, and the high angle diffraction pattern.

Note added in proof. The 5·1 Å reflexion characteristic of α-protein structure has now been seen in diffraction patterns from the taenia coli muscle (J. L., F. R. P., P. J. V. and J. M. Squire), as has the 72 Å meridional reflexion due to myosin. Observations made on sectioned material with the electron microscope (J. L. and J. V. Small) show that, in this muscle, myosin is present in very long ribbon-like elements the individual dimensions of which account for the shape of the meridional reflexions. We also see small scale arrays of actin filaments the orderly packing of which is responsible for the observed equatorial diffraction pattern.

Platelet Adhesion in Rabbit Arteries observed by Scanning and Transmission Electron Microscopy

THE adhesion of blood platelets to the wall of an artery at a site where the endothelium has been destroyed is usually the first event in the formation of an experimental thrombus. When the endothelium is removed from the mid-abdominal aorta of a rabbit, by passing a roughened probe into the lumen, only single platelets or small platelet clumps adhere to the denuded surface when the blood flow is restored[1]. Because in these circumstances the platelets attached to the wall are not obscured by an overlying mass of thrombus material, the preparation provides a suitable model for studying the morphology of the adherent platelets both by scanning electron microscopy *en face* and by conventional transverse sections.

The segment of aorta is fixed (glutaraldehyde, followed by osmium tetroxide) and dehydrated through graded ethanol at arterial pressure so that its normal dimensions are preserved[2]. It is then opened longitudinally so that the injured area can be identified, and is divided into two. One part is mounted flat with the inner surface uppermost on the standard chuck for the Stereoscan scanning microscope. The second part is further divided into thin transverse or longitudinal sections and embedded in 'Araldite'. This communication describes the preliminary results obtained from such a procedure.

The appearances of adherent platelets shown by scanning electron microscopy (Fig. 1) are very similar to those described for platelets adherent to a foreign surface such as glass[3]. Many have a central hump, suggesting that the organelles are concentrated in this region; others are more flattened and may correspond to those which in transverse section appear to have lost their granules. Long cytoplasmic projections, or pseudopods, some of them branched, extend from the peripheral hyaloplasm. This spreading seems to occur fairly evenly over the surface of the exposed internal elastic lamina with no clear relationship to the ramifying sub-endothelial fibres on its surface. Transverse sections confirm the presence of elongated pseudopodia and reveal a narrow space between the platelet surface membrane occupied by occasional fibres and diffuse material. The latter stains intensely when the dye ruthenium red is added to the fixative (ref. 4 and personal communication from J. H. Luft) and probably represents the ground substance of the sub-endothelial space which is rich in polysaccharide complexes (Fig. 2).

Studies on the properties of platelets *in vitro* have

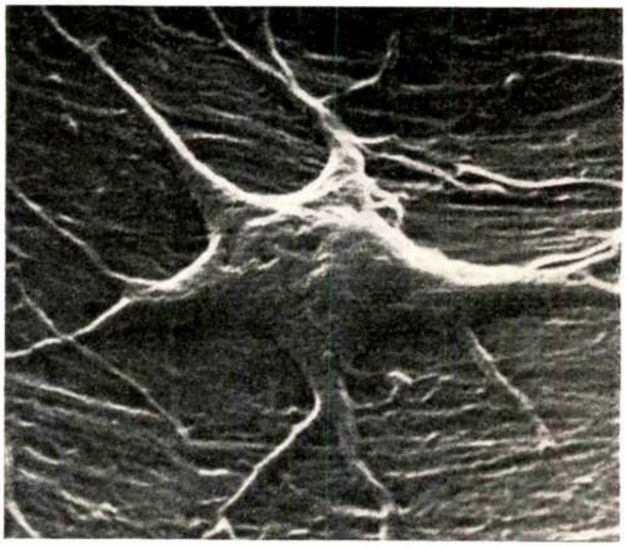

Fig. 1. Adherent platelet as seen by scanning electron microscopy. (×21,000.)

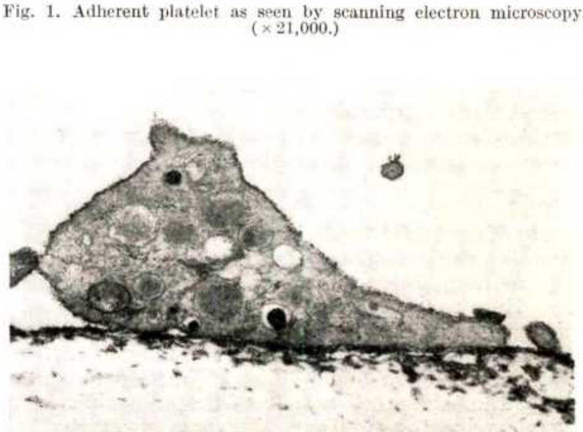

Fig. 2. Adherent platelet containing characteristic granules, in transverse section. Material on inner surface of internal elastic lamina is stained with ruthenium red. (×20,500.)

indicated that platelets will adhere readily to collagen, but not to elastin, and that mucopolysaccharides obtained from the ground substance of the aorta will not by themselves cause platelet aggregation[5]. Adhesion *in vivo* of platelets to collagen in the haemostatic plug[6] and to basement membrane in injured veins has been observed by electron microscopy[7]. The combination of scanning and transmission electron microscopy, which permits a three dimensional view of the platelets, indicates, however, that typical collagen fibres or basement membrane are not always present at the sites where platelets adhere; this keeps open the possibility that components of the injured intima other than collagen act differently in their native state and have a significant effect in platelet adhesion.

The micrograph in Fig. 1, taken on a Cambridge Mark IIa Stereoscan scanning microscope, is reproduced by permission of the Cambridge Instrument Company.

Inhibition by Bile Salts of the Jejunal Transport of 3-O-Methyl Glucose

THE action of bile salts on the intestinal absorption of fat is well known[1] although their role on the transport of water soluble substrates remains poorly defined. Inhibition of monosaccharide transport by both unconjugated and conjugated bile salts has been reported[2,3]. Pope and co-workers, however, using highly purified preparations of bile salts in jejunal loops from normal rats, concluded that conjugated bile salts have no physiological action on the absorption of glucose in normal animals[5]. We have reassessed this problem in bile depleted rats using extracorporeally perfused segments of rat jejunum removed with their intact circulation.

A bile fistula was established by inserting a cannula in the common duct 5 mm distal to the bifurcation of the hepatic ducts in ten male Sprague–Dawley rats weighing 200 to 280 g. The position of the cannula did not interfere with a normal flow of pancreatic secretions as shown by trypsin assays[6]. The bile collected at 4° C and pooled had a bile salt concentration of 11 μmoles/ml. determined by a spectrofluorometric method[7]. A comparable number of animals were sham operated, the cannula lying in their peritoneal cavity. The two groups of animals were placed in restraining cages and offered *ad libitum* a 5 per cent sucrose solution containing 40 mequiv/l. of NaCl and 20 mequiv/l. of KCl. Forty-eight hours after operation, the absorption of 3-O-methyl glucose (3-O-MG), a non-metabolizable monosaccharide which shares the transport characteristics of glucose[8], was studied in segments of upper jejunum.

Under pentobarbital anaesthesia, 20 cm segments of upper jejunum immediately distal to the ligament of Treitz were completely removed from the animals and perfused extracorporeally through the superior mesenteric artery[9,10]. The blood perfusate consisted of 20 per cent washed bovine red cells suspended in a physiological electrolyte solution, 2·5 per cent dextran (mol. wt. 78,000), 2·5 per cent bovine serum albumin, 100 mg per cent of D-glucose and 100 mg per cent of 3-O-MG. It was oxygenated by means of a rotating mesh screen using a humidified 95 per cent O_2 and 5 per cent CO_2 gas mixture. The circulation was maintained at a rate of 2·5 ml./min by a servo-controlled peristaltic roller type pump with an asymmetrical head ('Ambec' extracorporeal perfusion unit, Beck, Colorado). Both ends of the jejunal segments were cannulated. The intestinal lumen was perfused at a rate of 1 ml./min with 100 mg per cent of 3-O-MG (Calbiochem, Los Angeles) and 2 μCi of ^{14}C-labelled 3-O-MG (New England Nuclear Corp., 5·3 mCi/mmole) in a physiological electrolyte solution or in pooled bile. Once the luminal perfusate was started, the total portal venous effluent was collected at one minute intervals and plasma ^{14}C was assayed in a Packard '300 Tri-Carb' liquid scintillation spectrometer. The percentage minute absorption (per cent abs./min) was calculated by dividing the product of the substrate concentration and the volume per min of the portal venous effluent by the mean luminal substrate concentration. The latter was considered equal to the average substrate concentration in the proximal and distal intestinal catheters. The per cent abs./min was then corrected per g of freeze-dried mesentery free bowel. Fig. 1 illustrates the perfusion sequence and the absorption characteristics observed in bile fistula and in sham animals. Results show a significantly increased absorption of 3-O-MG in the bile depleted animals (Table 1). On the other hand, the substitution of bile for the electrolyte solution as a vehicle for the substrate under study had no effect in either group of animals (Fig. 1).

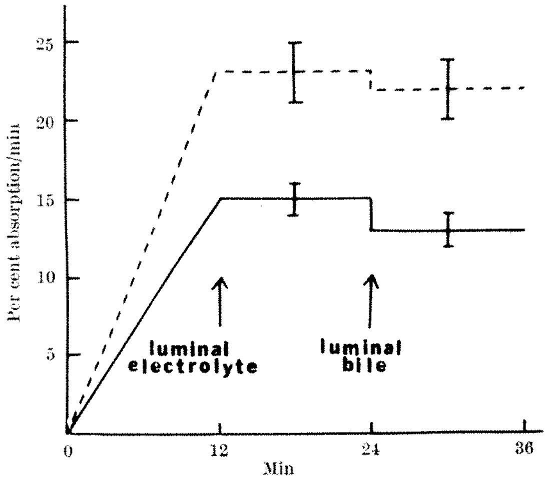

Fig. 1. Once placed in the tissue chamber at 37° C, the jejunal preparation was perfused for about 5 to 10 min before the constant luminal perfusion of 3-O-MG was started. As illustrated, the concentration of substrate in the venous effluent rose promptly. This accumulative tissue and vascular phase lasted 8 to 10 min and was followed by a relatively steady rate of substrate influx into the venous effluent. The portal venous ^{14}C activity was measured in duplicate from one minute samples taken throughout the two consecutive 12 min periods of luminal 3-O-MG electrolyte solution and the final 12 min interval during which pooled rat bile was the vehicle for the substrate. - - -, Bile fistula; ———, sham animals.

To validate this initial observation, three groups of ten rats with bile fistulae were studied. After creating the fistula, an intraduodenal cannula was positioned through a gastrostomy. The three groups of animals with bile fistulae were restrained, fasted and intraduodenally perfused for 48 h at a rate of 1 ml./h with either pooled rat bile, an electrolyte solution, or with a solution containing 35 μmoles/ml. of sodium taurocholate, the reported concentration of bile salts in rat bile[11]. The *p*H of these duodenal perfusates was 6·8 and their osmolality 285–310 mosM/kg. The commercial preparation of sodium taurocholate (Maybridge Research Chemicals, UK) was repurified by extracting an aqueous solution (*p*H 4·0) with diethyl ether five times. The acid *p*H was maintained between extractions. The final ether phase was decanted, flash evaporated at 24° C and the water phase lyophilized. Thin layer chromatography[12] showed trace amounts of other taurine conjugates, but no detectable unconjugated fractions. After 48 h of bile drainage and constant duodenal perfusion of either bile, electrolyte or sodium taurocholate, the weight loss of the animals averaged 11·4, 11·1 and 12·2 per cent for the three groups. The capacity of their isolated segments of upper jejunum to transport actively monosaccharides *in vitro* was assessed during a 30 min period of perfusion using an electrolyte solution of 100 mg per cent 3-O-MG and 2 μCi of ^{14}C-labelled 3-O-MG.

Table 1. PER CENT ABSORPTION PER MINUTE OF 3-O-MG/g DRY WEIGHT OF UPPER JEJUNUM PERFUSED *in vitro* AFTER 48 H OF BILE DEPLETION THROUGH A COMMON DUCT CANNULA

	No.	$\bar{X} \pm S.E.$	*P*
Sham	10	15·1 ± 1·13	< 0·01
Bile fistula	10	23·2 ± 1·95	

Table 2. PER CENT ABSORPTION OF 3-O-MG/g DRY WEIGHT OF UPPER JEJUNUM PERFUSED *in vitro*

	No.	$X \pm S.E.$	*P*
Pooled bile	10	20·6 ± 1·04	< 0·001
Electrolyte solution	10	33·6 ± 1·86	< 0·001
Sodium taurocholate	10	21·8 ± 1·07	

These intestinal preparations were studied in bile fistula animals after 48 h of continuous intraduodenal perfusion of either pooled rat bile, electrolyte solution or sodium taurocholate.

Table 3. DETERMINATIONS ON MUCOSAL SCRAPINGS

Determination	Perfusion liquid Electrolyte (5 rats)	Pooled bile (5 rats)	Taurocholate (5 rats)
Protein (mg/g wet weight)	113·3 ± 9·1	122 ± 9·4	100·3 ± 8·6
Hexokinase (nmoles of glucose metabolized per min/mg protein)	22·2 ± 2·9	24·1 ± 2·7	27·7 ± 2·5
Na^+, K^+ stimulated ATPase (μg P_i/mg protein/h)	86·2 ± 17·5	94·9 ± 19·1	77·7 ± 13·6
Glucose (mg/100 g wet tissue)	67·2 ± 8·0	68·1 ± 8·4	63·3 ± 7·7

Homogenates of mucosal scrapings frozen at −70° C were used for the determination of protein[13], hexokinase[14] and Na^+, K^+ stimulated ATPase[15]. Glucose determinations were carried out on whole bowel wall homogenates[16]. The results are expressed as means ± *S.E.* and show no significant difference between the three groups of animals.

Table 2 shows a marked difference in the *in vitro* per cent abs./min of 3-O-MG between the bile fistula rats perfused *in vivo* with the electrolyte solution and those perfused with either bile or sodium taurocholate for 48 h. There was no correlation between absorptive capacity and metabolic function as assessed by protein, hexokinase, Na^+, K^+ stimulated ATPase and glucose determinations carried out on tissue taken immediately adjacent to the jejunal segment removed from the animal (Table 3).

Thus when a segment of jejunum was removed from a bile depleted animal and perfused, it absorbed 3-O-MG more efficiently than a similar segment from a sham operated rat. In those bile fistula animals where bile depletion was countered by a constant *in vivo* bile infusion, however, the increase expected in bile fistula animals was not seen. More important, the experiments with a preparation of sodium taurocholate suggest that the biliary constituent responsible for modifying monosaccharide transport is a bile salt. On the other hand, when bile was acutely perfused through the *in vitro* jejunal preparation from both bile depleted and sham animals, it failed to affect the absorption of 3-O-methyl glucose (Fig. 1). This indicates that bile probably does not have a detergent effect modifying permeability characteristics of intestinal epithelial cells to monosaccharides. The observation that chronically administered bile salts in bile fistula animals exert an inhibitory effect on 3-O-MG transport is compatible with the idea that bile salts interfere with and modulate the absorption of monosaccharides. Because there was no apparent relationship between the absorption of 3-O-MG and metabolic function in the presence and absence of bile salts (Table 1), it is tempting to postulate that bile salts may have a specific effect on the monosaccharide active transport system localized in the plasma membrane of epithelial cell microvilli[17].

We thank Drs F. Kern and S. Gordon for their help and Miss C. Trombley and Mrs A. Montgomery for assistance. This investigation was supported by the US National Institutes of Health and Mead Johnson.

Parathyroid Hormone Secretion *in vitro*: Regulation by Calcium and Magnesium Ions

CONSIDERABLE evidence[1–5] has indicated that the secretion rate of parathyroid hormone (PTH) is controlled by the serum calcium; the release of hormone is proportional to calcium ion concentration, variations of which are followed within minutes by changes in circulating hormone activity[6]. Furthermore, studies[7–9] in animals suggest that the effects of magnesium ion on parathyroid function may resemble those of calcium.

We have recently developed an organ culture system utilizing normal bovine parathyroid tissue, which has provided direct evidence that the release of PTH is inversely proportional to both calcium and magnesium ion concentrations. Fresh bovine parathyroid glands were obtained at the time of slaughter and placed in sterile Earle's solution containing penicillin and streptomycin. The glands were plated out as 1 mm³ explants on stainless steel grids in organ culture dishes within 1 to 3 h. Incubations were performed in BGJ chemically defined medium modified by the addition of glycine and proline[10,11] plus 10 per cent foetal calf serum. Radioactive leucine (New England Nuclear) was added to low leucine medium in some experiments (0·5 μCi/ml. of ^{14}C-leucine). Tissue culture fluid was changed daily according to the experimental design, and the culture was continuously incubated in 5 per cent carbon dioxide in air. Calcium and magnesium ion concentrations were varied over the ranges 1–2·6 mM and 0·6–1·5 mM respectively, keeping chloride, phosphate and bicarbonate concentrations constant. Bovine PTH released into the tissue culture medium was measured by a highly specific and sensitive radio immunoassay[12], utilizing dextran coated charcoal to separate bound and free hormone[13]. In the perfusion studies, three or four explants were placed in a microchamber and perfused with varying calcium concentrations at a rate of 1·0 ml./h with a Sage pump. The calcium concentration of the perfusate was lowered in stepwise fashion, and three 30 min perfusates were collected at each calcium concentration.

Explants of normal glands remained functionally and histologically intact for periods as long as 3–4 weeks. Although central portions of the tissue eventually became necrotic, new cell growth at the borders was noted, and a functional layer of peripheral epithelial cells remained. Synthesis of new hormone in the tissue was documented by the incorporation of ^{14}C-leucine into a labelled protein (in tissue extracts and culture medium) which could be eluted on a column of 'Sephadex *G*-75' in a position corresponding to that of ^{131}I-labelled bovine PTH. Furthermore, ^{14}C-labelled hormone could be bound to antibodies against bovine PTH (moving its elution position on 'Sephadex *G*-75' to the void volume of the column) and then displaced by unlabelled bovine hormone, confirming its immunological identity with bovine PTH. Unlabelled PTH released into the tissue culture fluid behaved like purified bovine PTH in the radio immunoassay because it caused parallel displacement of ^{131}I-labelled hormone bound to antibody. When the medium was changed daily, and calcium concentrations maintained at either high (2·6 mM) or low levels (1·0 mM) for 2 day periods, hormone release varied in reciprocal fashion (Fig. 1*A*). The amount of hormone released into the medium varied between 0·1 and 1·6 μg/day. Tissue exposed to constant calcium concentrations of 2·0 mM, on the other hand, showed no significant variations in hormone release (dotted line, Figs. 1*A* and *B*). Similar variations in medium magnesium concentration (with calcium constant at 2·0 mM) in the range of 0·6 to 1·5 mM resulted in reciprocal variations in PTH secretion (Fig. 1*B*). In leucine incorporation studies performed under identical conditions, the amount of newly synthesized hormone secreted into the medium paralleled the release of unlabelled hormone.

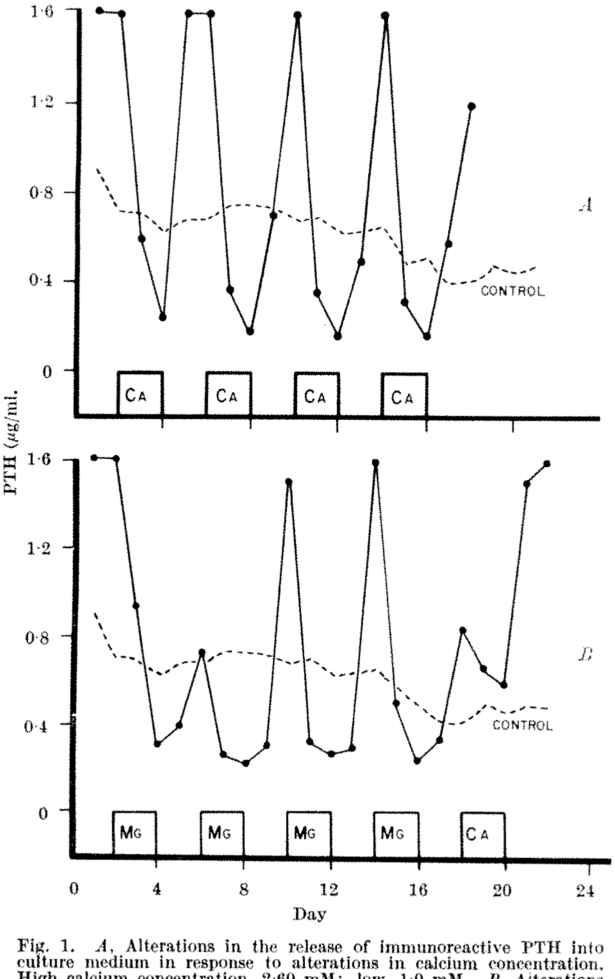

Fig. 1. *A*, Alterations in the release of immunoreactive PTH into culture medium in response to alterations in calcium concentration. High calcium concentration, 2·60 mM; low, 1·0 mM. *B*, Alterations in the release of immunoreactive PTH into medium in response to alterations in magnesium concentration. High magnesium concentration, 1·5 mM; low, 0·6 mM. Dotted line indicates results of constant calcium (2·0 mM) control culture.

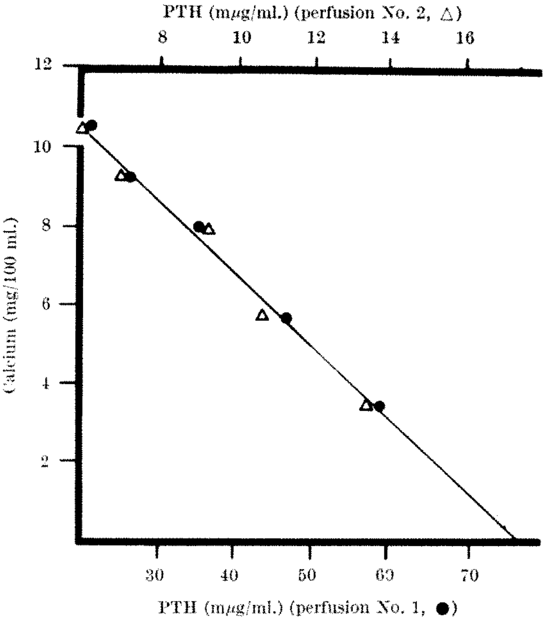

Fig. 2. Variations in PTH released from perfused explants at five calcium concentrations in two separate experiments. Each point represents mean of three 30 min perfusates.

In separate perfusion experiments, calcium concentration which was 2·6 mM (10·4 mg per cent) initially was sequentially decreased to 1·0 mM (4 mg per cent) in four steps. Parathyroid hormone released into the fluid was inversely related to the perfusing calcium concentration and was a proportional function when plotted against the calcium concentration of the medium (Fig. 2).

The current report describes an *in vitro* system which synthesizes PTH and which responds rapidly to changes in calcium concentration by varying the secretion of hormone. These studies fully confirm earlier observations[3] *in vivo* of a linear relationship between serum calcium concentration and the release of hormone and, furthermore, provide definite evidence that magnesium ion has a calcium like effect on parathyroid function. In a recent detailed and quantitative comparison of the effects of calcium and magnesium ions on parathyroid gland metabolism (J. H. Targovnik and L. M. S., in preparation), it is apparent that the two cations are equipotent in blocking hormone release. Further studies of the mechanism of this effect as well as the effects of the two ions on hormone synthesis are in progress.

Complexes between Acetylcholine and Catecholamines and their Tolerance to Mental Illness

THE biochemical theories of schizophrenia based on the presence of endogenous psychotogenic agents[1] relate to the hypothesis first advanced by Osmond and Smythies[2] of an aberrant catecholamine metabolism and take into account the studies on experimental animals and humans[3] which demonstrated the psychotomimetic properties of aminochromes.

Recently the importance of a direct chemical interaction between central chemical transmitters and neurotropic drugs has been pointed out[4] and postulated as the chief event responsible for the pharmacodynamic effect of some neurotropic drugs[5]. Moreover, the possibility of an interference between a well known[6] oxidation product of a central neurotransmitter such as noradrenaline and another neurotransmitter such as acetylcholine has been established[7]. In fact, acetylcholine is able to interact with oxidized noradrenaline, yielding a molecular complex that is stable toward further transformation to adrenolutin brought about by ascorbic acid.

In this work a new medium for the interaction was chosen with conductivity and oxidative properties quite close to the ones found for whole brain homogenates. A mixture of Tris-HCl 0·1 M *p*H 7·4 and dioxane (1 : 10) was used with a conductivity of about 3 microSiemens and an E_h value of 185 mV. Whole rabbit brain homogenates showed an average conductivity of about 5 microSiemens and E_h value of about 120 mV (with a radiometer *TTT 1C* equipped with platine-calomel electrode). The values found for the homogenate thus agree quite well with those found for the Tris-dioxane medium. This medium, in fact, brings about the spontaneous transformation of catecholamines first to aminochromes and later to dihydroxyindoles as shown by spectral and chromatographic evidence.

Table 1 shows the characteristics of the interaction between acetylcholine and oxidation products of noradrenaline both in the excited state and in the ground state of the molecules as shown by the good parallelism of spectral, chromatographic and conductometric data. The non-additive conductivity of acetylcholine and noradrenaline is mostly evident in the Tris-dioxane medium and the same is true for the chromatographic mobility that is slower for the acetylcholine–noradrenaline mixture in the Tris-dioxane medium. Further, the typical visible and ultraviolet absorption of aminochromes and a significant interaction documented by difference spectra is found only with the Tris-dioxane medium. If dopamine is used instead of noradrenaline a similar interaction can be noted.

Infrared spectra were taken after evaporating the solutions listed in Table 1 and redissolving the residue in chloroform. The chief variations were observed with Tris-dioxane medium; a new 1,040 cm^{-1} band not shown in either compound alone appeared in the acetylcholine–noradrenaline mixture. This band might be due to deformation and skeletal vibration of the CO–O–C portion of acetylcholine. A new stretching vibration appeared also in the 3,600–3,000 cm^{-1} region which can be assigned to the free OH of noradrenochrome. These results support the previous hypothesis[7] concerning a possible interaction between the O–C–C–N system common to the two molecules. The main finding reported here and in the preceding study[7] is related to the stabilization of toxic oxidation products of central catecholamines such as noradrenaline and dopamine by the central chemical transmitter acetylcholine. A detailed chemical study of such an interaction is now in progress.

The effects of ascorbic acid and nicotinamide, a compound used for the therapy of mental illness[8], are of great interest if studied on our system. In fact, the velocity of autoxidation of noradrenaline is increased by both acetylcholine and nicotinamide as shown in Table 2. It seems that either compound is able to form molecular complexes with aminochrome, but the effect of ascorbic acid strongly differs for each complex, as documented polarographically and by fluorimetric measurements (Table 3).

By measuring the velocity of noradrenochrome formation in the presence of different concentrations of acetylcholine and nicotinamide two apparent dissociation

* The data reported here were collected 1 h after the solutions were prepared.

† The products were obtained from Calbiochem. The initial solutions were 0·1 M in water, Tris-HCl 0·1 M, *p*H 7·4 or Tris-dioxane (1 : 10). Dioxane (Merck, puriss.) was used without redistillation.

‡ The solvents indicated were used for the dilutions 1 : 100 or 1 : 1,000 made before taking the spectra.

§ The spectra were recorded with a Cary 15 recording spectrophotometer.

‖ Double-compartment cells were used. The acetylcholine–noradrenaline mixture was put into the upper chamber together with solvent and the two separate solutions of acetylcholine and noradrenaline were put into the lower chamber.

¶ Thin layer chromatography on silica gel (Eastman sheets 20 × 20 type K 301 R2) with acetic acid–water 2 per cent as solvent was used. The spots were detected after spraying with 10 per cent methanolic KOH. The fluorescence was viewed in an Original Hahau (No. 5201) apparatus with excitation wavelength of 3600 Å. B = blue, Y = yellow, G = green, BG = blue-green.

** A conductivity-meter CDM 2 radiometer type was used.

Table 2. MOLECULAR COMPLEXES OF NORADRENOCHROME WITH ACETYLCHOLINE AND NICOTINAMIDE

Compound added to noradrenaline*	Spectrophotometric velocity of autoxidation †	Polarographic relative velocity of autoxidation ‡	Chromatographic mobility§	
			Rf_1	Rf_2

* To 1·5 ml. of noradrenaline 1×10^{-3} M in Tris-HCl *p*H 7·4 0·1 M and dioxane (1 : 10) 1·5 ml. of acetylcholine or nicotinamide 1×10^{-2} M are added.

† Noradrenochrome formation is followed with a Beckman DB recording spectrophotometer as $\Delta E_{497\ \mathrm{nm}}$ in 10 min.

‡ A Gilson ME apparatus equipped with a Clark oxygen electrode is used.

§ Thin layer chromatography on silica gel with acetic acid 2 per cent in water as solvent is used. The spots are detected with an ultraviolet lamp after spraying the chromatoplates with 10 per cent methanolic KOH.

Table 3. EFFECT OF ASCORBIC ACID ON ACETYLCHOLINE–NORADRENOCHROME AND NICOTINAMIDE–NORADRENOCHROME COMPLEXES

Compound added to noradrenaline*	Relative velocity of formation of fluorescent compound †	Relative velocity of polarographic reduction ‡
None	100	100
Acetylcholine	19	36
Nicotinamide	590	430

* The solutions are the same as those described in the caption to Table 1. They are used 1 h after acetylcholine or nicotinamide addition. 0·03 ml. of 0·5 per cent ascorbic acid in water is added and the relative velocities of formation of reduction derivatives are measured.

† An Eppendorf recording spectrophotometer with the fluorescence attachment is used with 400 nm excitation and 500 nm emission filters.

‡ A Gilson ME oxygraph as described in Table 2 is used.

constants for acetylcholine–noradrenochrome ($K_1 = 1{\cdot}75 \times 10^{-4}$ M) and nicotinamide–noradrenochrome ($K_2 = 4{\cdot}16 \times 10^{-3}$ M) complexes were calculated.

From these data it appears that nicotinamide is able to compete with acetylcholine for noradrenochrome. In fact, a similar effect was observed by studying the formation of molecular complexes between thiamine and central chemical transmitters[9]. The acetylcholine–noradrenochrome complex is relatively stable toward reduction to dihydroxyindole by ascorbic acid as already shown[7], whereas the reduction of nicotinamide–noradrenochrome complex is much faster than the reduction of noradrenochrome alone. The data obtained after chromatography agree with the fluorescence measurements. In fact, the spot (Table 2) corresponding to adrenolutin[6] is present only when nicotinamide is added and the rate of formation of fluorescence products is maximal in the presence of nicotinamide.

A general scheme can summarize these results as follows

$$\begin{tikzcd}
 & \text{nicotinamide} \arrow[r] & \text{complex 2} \arrow[d] \\
\text{catecholamine} \arrow[r] & \text{aminochrome} \arrow[u] \arrow[r] \arrow[d] & \text{dihydroxyindole} \\
 & \text{acetylcholine} \arrow[r] & \text{complex 1}
\end{tikzcd}$$

If we consider adrenochrome reduction derivatives as non-toxic excretion products of the psychotogen aminochromes, a rationale for the clinical use of nicotinamide in megadoses[8] as a therapy for mental illness is now provided. In fact, our data suggest a chemical explanation for mental illness which may offer an alternative to the theory of orthomolecular psychiatry proposed by Pauling[10].

We can postulate that if a central catecholamine is leaking at any synapse devoid of the enzymatic system that destroys it, the slightly oxidative conditions together with the hydrophobicity of the medium are sufficient to bring about a physiological aminochrome formation, as occurs in our *in vitro* system. If this takes place at the level of cholinergic synapses the aminochromes so formed can accumulate and be stabilized by acetylcholine.

The leak of catecholamine and the stabilization of its oxidation products could produce an aberrant communication which, on the one hand, might be the chemical event leading to a short circuit between adrenergic and cholinergic systems and, on the other hand, might be the origin of irritative foci of stabilized psychotogenic agents at cortical level.

Both effects could possibly explain the onset of mental illness.

I thank Professor Linus Pauling and Dr Emile Zuckerkandl for scientific, moral and financial support.

Changes in Enzymes involved in the Biosynthesis and Metabolism of Noradrenaline and Adrenaline after Psychosocial Stimulation

THE important role of catecholamines in behaviour has been recognized[1]. Increased adrenaline and noradrenaline excretion has been observed in anxiety-provoking situations and in states of anger and aggression[2,3]. Drugs used in affective disorders cause marked changes in uptake, storage, release and metabolism of the neurotransmitter noradrenaline in the peripheral and central nervous systems[4,5]. Because of the growing understanding of the implication of catecholamines in behavioural changes, we examined the effect of psychosocial stimulation and deprivation on the activity of the enzymes involved in the biosynthesis and metabolism of catecholamines. Groups of mice were raised in social isolation or were subjected to prolonged and increased social interaction, and the catecholamine synthesizing (tyrosine hydroxylase and phenylethanolamine N-methyltransferase) and metabolizing (monoamine oxidase and catecholamine-O-methyl transferase) enzymes were examined in the adrenal gland. We wish to report marked changes in enzymes involved in catecholamine synthesis and metabolism in the adrenal glands of these mice.

Control groups consisted of mice which had normal nursing and sibling contact until three to four weeks old and were then weaned. The sexes were separated and maintained six to eight siblings per standard cage 27 × 14 × 13 cm until eight months of age. Stimulus-deprived mice were removed from mother and sibling contact 24 h after birth for 2 h a day for 14 days. They were then isolated in pint size glass containers one-third full of wood shavings. A paper towel was taped around each jar to prevent visual contact, but they retained access to olfactory and auditory stimuli. The mice remained isolated until eight months of age. Groups which had increased social stimulation were deprived of mother and sibling contact 2 h per day for 14 days, as described for the stimulus deprived group. The sexes were separated and six to eight siblings were placed in a standard cage for 90 days. Ten males and ten females were then placed in a communicating box system until they were eight months old, as previously described[6]. This consisted of six cages connected with narrow tubes. Another tube from each cage led into a central box containing food and water. Floor space per mouse was about twice as much as that of the standard cage, but males and females could now intermingle. Such a box system forced the mice into frequent dominance-submission choices and increased social stimulation. At eight months, all males were killed with ether, the adrenals rapidly removed, cleaned, weighed and then frozen. Each adrenal gland was homogenized in 1 ml. of ice-cold isotonic sucrose with glass Duall homogenizer and an aliquot taken for the determination of noradrenaline[7]. The remaining homogenate was centrifuged at 27,000*g*, tyrosine hydroxylase[8], phenylethanolamine N-methyltransferase (PNMT)[9], and catechol-O-methyl transferase (COMT)[10] were assayed in the supernatant fraction and monoamine oxidase (MAO)[11] was determined in the particulate fraction.

Tyrosine hydroxylase, the initial and rate-limiting enzyme in catecholamine formation, is localized in sympathetic nerves and in the adrenal gland. PNMT is restricted to the adrenal medulla and certain areas of the brain and converts noradrenaline to adrenaline. In the socially deprived mice there was a significant decrease in adrenal tyrosine hydroxylase and PNMT activity (Table 1). The noradrenaline and adrenaline content was slightly but not significantly lower in these animals. No changes in MAO or COMT activity were observed. There was a marked elevation in tyrosine hydroxylase, PNMT, and MAO activity and in noradrenaline and adrenaline content in the adrenals of psychosocially stimulated mice, but no change in COMT activity. Adrenal gland weight was elevated in both deprived and stimulated mice.

Table 1. EFFECT OF PSYCHOSOCIAL STIMULATION ON THE ACTIVITY OF CATECHOLAMINE FORMING AND METABOLIZING ENZYMES IN MALE MOUSE ADRENALS

Treatment	Adrenal (weight/mg)	PNMT (units)	Tyrosine hydroxylase (units)	MAO (units)

* $P < 0·001$. † $P < 0·01$. ‡ $P < 0·05$.

Results are expressed as mean ± *S.E.* per adrenal. One unit of enzyme activity is the pmole product formed per h.

These results demonstrate changes in enzymes concerned with the biosynthesis of noradrenaline and adrenaline in the adrenal glands of mice subjected to different social interactions. In socially deprived mice there was a fall in tyrosine hydroxylase and PNMT activity although adrenal weight was increased, while in socially stimulated mice there was a rise in both biosynthetic enzymes and one metabolizing enzyme (MAO). The elevation of these enzymes might be the result of increased discharge of corticoids from the adrenal cortex, or an increased stimulation of the adrenal gland by sympathetic nerves. We have previously shown that tyrosine hydroxylase and PNMT can be elevated by a reflex increase in sympathetic nerve activity, but not by pituitary or corticoid hormones[12]. Furthermore, it was found that the increase in enzyme activity was trans-synaptically induced, dependent on new protein synthesis, and required one to three days before an elevation was apparent[13]. Prolonged, forced immobilization of rats also produces an elevation of tyrosine hydroxylase and PNMT activity and this rise could be abolished by cutting the splanchnic nerve to the adrenal gland (personal communication of R. Kvetnausky, I. J. Kopin and V. Weise). These findings suggest that the increase in the catecholamine-forming enzymes in psychosocial stimulation may also be neuronally mediated and is not an immediate response, as in the case of a sudden discharge of noradrenaline and adrenaline in states of anger, fear or aggression[2,3].

A reduction of adrenal PNMT and tyrosine hydroxylase activity occurs after hypophysectomy and this decrease can be prevented with ACTH. Adrenal tyrosine hydroxylase activity decreases after cutting the splanchnic nerve to the adrenal[14]. Whether the reduced PNMT and tyrosine hydroxylase activity in psychosocially deprived animals is due to a depletion of ACTH, reduced sympathetic nerve stimulation or other factors remains to be established.

Direct Postsynaptic Responses to Stimulation of Serotonin-containing Neurones

THERE is one giant serotonin-containing neurone in each metacerebral ganglion of the slug *Limax maximus* and of the snail *Helix pomatia*. These cells can be identified histochemically and their content of serotonin can be measured by bioassay of individually dissected neurones. The amine is localized in small electron dense granules in the cytoplasm of these cells and also, in certain conditions, in particles with the appearance of lysosomes (ref. 1 and unpublished data of G. A. C. and N. N. Osborne). Dye injection experiments with 'Procion Yellow', using the method of Stretton and Kravitz[2], show that each giant neurone in *Helix pomatia* gives off three main axonal branches. One branch passes across the cerebral commissure to the other group of cerebral ganglia, another can be traced to the ipsilateral cerebral-buccal connective, and the third passes into the ipsilateral exterior lip nerve.

Kandel and Tauc[3,4] have previously studied the membrane properties of these neurones in *Helix aspersa* and *Helix pomatia* and they have discovered that they show a high degree of anomalous rectification. They also showed, using electrophysiological methods, that each cell sends an axon to the ipsilateral exterior lip nerve and one to each cerebral-buccal connective.

In this study a search was made for cells directly innervated by these giant serotonin-containing neurones in *Helix pomatia*. The circum-oesophageal ganglionic complex, together with the buccal ganglia and connecting nerves, were dissected from active *Helix pomatia* and pinned to a nylon sheet fixed at the bottom of a small bath (volume 0·7 ml.). The preparation was perfused with snail saline[5]. Double-barrelled glass micro-electrodes were used to impale the giant cell and to explore possible postsynaptic cells. One barrel was filled with 3 M KCl and used for recording and the other, used for applying current, was filled with 0·6 M Na_2SO_4. Input leads from the electrodes were fed through cathode followers to a dual beam oscilloscope.

Giant serotonin cells usually fired a burst of spikes when impaled with a micro-electrode and then remained inactive. They were made to fire action potentials by passing a depolarizing pulse of 1 s or shorter duration through the second electrode. In each buccal ganglion a neurone was found which was stimulated by a burst of spikes in a giant serotonin cell. The cell was located close to the entry of the cerebral-buccal connective in each ganglion. The response recorded in some preparations was a slight depolarization at normal membrane potential (Fig. 1*a*) which was usually within the range of 50 to 60 mV. In other preparations, usually when the buccal cell showed some prior spike activity, a burst of spikes in a giant serotonin cell resulted in depolarization and a spike firing in the buccal cell. In a few preparations a small individual response was recorded with each spike fired in a giant serotonin cell. There was facilitation of such responses with repetitive stimulation and the potentials summed (Fig. 1*b*). There was a constant delay of about 100 ms in appearance of these potentials, suggesting a direct link between the giant serotonin cell and the buccal cell described.

Further information on the connexions between the cells was obtained in other preparations by hyperpolarizing one of the buccal cells described and repeatedly stimulating a giant serotonin cell. The size of the responses varied slightly from one preparation to another, but they were increased in amplitude by hyperpolarization. The potentials summed with repeated stimulation of a giant cell and in most cases facilitation of the responses could be observed. Increasing the level of hyperpolarization did not result in a loss of the potentials. Depolarizing pulses of different durations which did not result in spike firing in a giant cell did not cause any potential changes in the buccal cells.

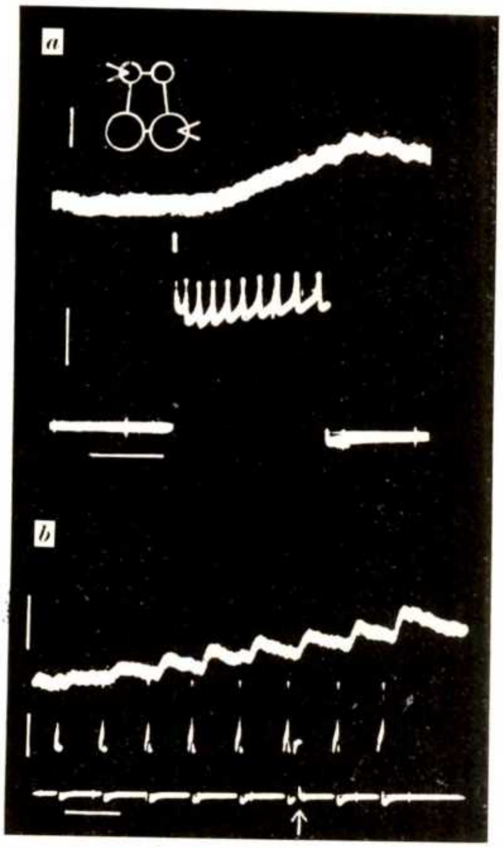

Fig. 1. Responses of a cell of the left buccal ganglion to spike firing in the right giant serotonin cell. The records are from two preparations. The buccal cell response is recorded on the upper beam in each case. (Sometimes, as in *a*, a giant serotonin cell would not fire spikes without relatively intense depolarizing pulses. Frequently axon spikes alone were recorded in these conditions.) In *b*, 50 ms depolarizing pulses, each resulting in only one spike, were applied to the giant serotonin cell. Each spike was followed by a small depolarizing potential in the buccal cell. The responses summed and were facilitated with repeated stimulation. A square wave alone did not affect the buccal cell (arrow). Calibrations: upper beam 2 mV; lower beam 20 mV; 0·5 s.

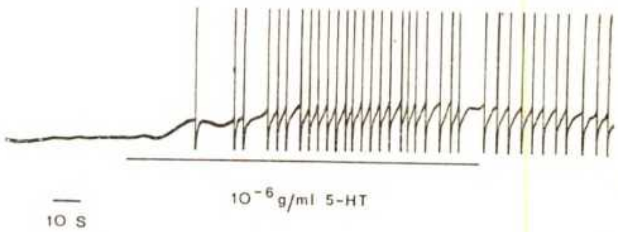

Fig. 2. Response of a cell, of the left buccal ganglion, which was previously shown to respond to spikes in the left giant serotonin cell, to perfusion with serotonin (5-HT). (The pen recorder did not record the full amplitude of the spikes.)

The data suggest that the small potentials observed are chemically mediated excitatory postsynaptic potentials (EPSPs). The view that the linkage was monosynaptic was supported by the observations that the EPSPs could not be lost by repeated stimulation, and the delay in appearance of EPSPs was always constant in a given experiment at about 100 ms.

The delay in response of the buccal cell was about what would be expected from information on conduction velocity of spikes in gastropod nerves. Conduction velocity along the intestinal nerve of *Helix pomatia* is at 5 cm/s (ref. 7). The distance between the giant serotonin cells and the buccal ganglia is about 0·7 cm.

Each of the two giant serotonin cells had an input on to a cell in each buccal ganglion and the conduction time for ipsilateral and contralateral connexions was observed to be the same. In some preparations both giant serotonin cells were stimulated while recording from the same buccal cell. No consistent difference in responses was observed depending on whether one or the other of the giant serotonin cells was stimulated.

It is thought that serotonin may be a transmitter substance in molluscs[7]. If this is the case with the giant serotonin cells, it would be expected that buccal cells would be activated by the amine. This was, indeed, shown to be so. The cells were depolarized and started firing spikes when serotonin, at a concentration of 10^{-7} g/ml. or greater, was added to the perfusion liquid (Fig. 2), whereas the giant serotonin cells were not depolarized and generally did not spike when the amine was added. Reduction in the potential, produced by applying a constant hyperpolarizing current, when serotonin was added to the bath showed that the amine increases membrane conductance of the specified buccal cells. Acetylcholine also stimulated the postsynaptic buccal neurone (as well as the giant serotonin cells). With respect to this observation, it may be important that each of the buccal cells receives at least one excitation input other than those from the giant serotonin cells. Dopamine, in concentrations of about 10^{-7} g/ml., hyperpolarized the postsynaptic cells. In the case of each of these drugs the responses of the specified buccal cells resemble those of the "CILDA cells" of gastropods which have been shown to have specific serotonin receptors[8,9].

The response of the cells in the buccal ganglia to activation of the giant serotonin cells was blocked with relatively high concentrations of the serotonin antagonists lysergic acid diethylamide (5×10^{-5} g/ml.) and "Methysergide" (10^{-4} g/ml.) but not by perfusing lower concentrations of these drugs for periods up to about 15 min. Further studies, however, need to be completed in order to evaluate the significance of the experiments with high concentrations of the blocking drugs in view of the observations[10] that the closely related compound 2-bromolysergic acid diethylamide can interfere with axonal conduction in another gastropod mollusc, *Aplysia*.

These results show that two symmetrically arranged serotonin-containing neurones form excitatory synaptic links with other neurones in the snail brain. They also provide evidence that serotonin is a transmitter in the central nervous system of the snail. The system that I have described may provide a favourable preparation for further pharmacological studies with drugs which modify the effects, or levels, of serotonin in nervous tissue.

I thank the MRC for financial support and Mr C. J. Roemmélé and Mr J. Brown for technical assistance.

Acute Toxicity of Aflatoxin B_1 in Wethers

THE original objective of this study was the preparation of milligram quantities of aflatoxin M_1. Holzapfel *et al.*[1] and Masri *et al.*[2] had collected sufficient quantities of the toxin from the urine of sheep which had eaten food containing aflatoxin B_1 for structural studies. We administered an exploratory dose of 4 mg of aflatoxin B_1/kg, a conservative value compared with a reported single dose LD_{50} of approximately 500 mg/kg (ref. 3). This was lethal to our wether. In subsequent correspondence Purchase advised that an (intraperitoneal) dose of 2 mg/kg had killed a Merino sheep, and Masri noted that a repeated oral dose of 0·38 mg/kg per day for seven days was lethal to both a Hampshire ewe and a crossbred western white-face wether. If the toxin is to be given over a period of time, a sublethal dose must be used. We undertook a toxicological study to satisfy this requirement and now report the results of our LD_{50} study.

The aflatoxin B_1 was obtained from extracts of cultures of *Aspergillus flavus* (FDA, DM Isolate No. M141) grown on sterile moist rice and purified by the procedure of Rodricks[4]. Recrystallization from chloroform yielded aflatoxin B_1 of 98 per cent purity based on thin layer chromatography and ultraviolet analysis (λ_{max} (361 nm) in methanol, ε 21,500). The required quantities of aflatoxin B_1 were weighed into gelatine capsules which were completely filled with powdered sucrose and sealed.

The animals used were two year old wethers, crossbred Hampshire–Shropshire–Merino–Southdown and an experimental Morlam breed derived from crossbred Dorset–Rambouillet–Merino sheep. They were kept in individual metabolism stalls adapted from a design by Briggs and Gallup[5] which allowed separate collection of faeces and urine. A mixture of alfalfa, clover and timothy hay was freely offered, and a grain feed, Beltsville 20C, was restricted to 0·9 kg per animal each day. While the animals were in the stalls, rectal temperatures were taken, and the droppings and general clinical appearance were observed. Sheep showing irregular or questionable results and abnormal behaviour without treatment were rejected.

After dosing, the clinical signs and body temperatures were recorded at 2–5 h intervals. Laparotomy was performed on surviving sheep, usually at day 7 and again after several weeks, to follow the course of liver restitution. Dead animals were necropsied. If the sheep survived, faeces were collected for 5 days and urine for 3 days after dosing and analysed for the content of aflatoxins B_1 and M_1.

Another single exploratory dose was given at 1·28 mg/kg and multiple doses were given on successive days (shown in parentheses): 0·9 (2), 0·59 (2), 0·23 (2) and 0·14 (6) mg/kg to separate wethers. None of these died.

Table 1. ACUTE EFFECT OF AFLATOXIN B_1 ON 2 YEAR OLD WETHERS

Daily dose mg/kg body weight	Days	No. of animals	No. dead
4·00	1	3	3
2·84	1	3	3
2·00	1	3	1
1·42	1	3	0
1·28	1	1	0
0·90	2	1	0
0·59	2	1	0
0·23	2	1	0
0·14	6	1	0

The single dose LD_{50} for crossbred wethers, calculated by the Weil[6] procedure, was 2·0 with a 95 per cent confidence interval of 1·6 to 2·4 mg/kg, where, according to the notations used by Weil, $K=3$, $n=2$, $r=0$, 1, 2, 2, $d=0{\cdot}1505$ and $Da=1{\cdot}42$ mg/kg. When one Morlam wether was added to each group, the LD_{50} was 2·0 (1·7–2·6) mg/kg where $n=3$, $r=0$, 1, 3, 3, and the remaining constants are as before. The dosing and mortality data are summarized in Table 1.

Loss of appetite and diarrhoea occurred at 0·23 mg/kg and higher, and persisted several days after a sublethal dose. Excessive salivation, frothing at the mouth and increased rectal temperatures of 0·9° ($P<0{\cdot}025$) within 12 h were seen at 1·28 but not 0·59 mg/kg. Higher doses caused an increased rate of respiration and increased the temperature 1·5° C or more. Much mucus and some bloody rectal discharge accompanied the scours after days 1–2 among sheep dosed at 1·28–2·00 mg/kg.

All the sheep that died in 15–18 h had massive centrolobular necrosis of the liver. One animal, dosed at 4 mg/kg, which died on day 6, had marked centrolobular necrosis of the liver with necrotic bridges extending to contiguous central veins. This produced an apparent reversal of the normal lobular architecture in that the portal triads, and surrounding normal parenchyma, were now central to a new pseudolobular pattern.

In liver biopsies of surviving sheep on day 7 there was periportal congestion with widely dilated sinusoids and loss of liver cells in these areas. On day 53 there was still focal congestion, along with microfocal liver cell degeneration.

An oral dose of aflatoxin B_1 0·5 mg/kg followed by 1–2 weeks' rest and subsequent redosing at the same level was tolerated by several sheep. This schedule, however, may have contributed to the cause of later death in two wethers. Other schedules therefore need to be examined for converting aflatoxin B_1 to M_1 without endangering the animals.

The susceptibility of sheep to an acute aflatoxin poisoning is thus similar to that observed with other animal species[7]. A limited number of biopsy observations indicate that the animals require several months to recover from sublethal doses of aflatoxin B_1.

We thank Dr George M. Sidwell, Sheep Branch, ARC, USDA, Beltsville, for supplying several sheep and technical advice; and Mr James E. Jackson and Mr Harry E. Zimmerman, jun., for technical assistance.

Vertebrate Fauna from the Lower Trias of Australia

AUSTRALIA'S lack of abundant Permian and Triassic tetrapod vertebrate fauna has long been an enigma to palaeontologists. Both labyrinthodont and reptilian remains are common in South America, Southern Africa and Madagascar, and fairly common in India, while part of a labyrinthodont mandible has recently been reported from Antarctica[1]. Apart from a recent find in Western Australia, and a small collection from Tasmania, the few described Australian labyrinthodonts have been isolated specimens, while a single individual from Tasmania is the only Australian pre-Jurassic reptile.

In 1965 Alan Bartholomai, following up a report of bone in the previously barren Upper Rewan (Lower Trias) red beds south of Rolleston in Central Queensland, found scattered labyrinthodont and thecodont reptilian remains. He added to the collection in 1966 and 1968, and in September 1969 was joined in the field by Alex Ritchie and Kingsley Gregg from the Australian Museum, and by Anne Howie. Most of the remains were found as isolated bone fragments which had weathered out from the Rewan's banded red and lime green mudstone, a small proportion occurred in rare sandstone layers, while the smaller specimens tended to be preserved in purple ferruginous nodules.

Although the greater part of the collection consists of labyrinthodont remains (Fig. 1), it also contains dipnoan tooth plates, a small quantity of thecodont material and some twelve small skulls of the earliest known Australian reptiles. Dissociated remains of at least thirty labyrinthodonts were recovered and four partial skulls were found in association with postcranial material. The most common species is a small parotosaur while a second species has a broad skull with large, laterally placed orbits in the anterior half of the skull roof and prominent tabular horns. Apparently associated with this second skull type are poorly ossified neorhachitomous vertebrae. These specimens are being prepared in Sydney by Anne Howie, who will publish a full description later.

Alan Bartholomai is describing the small reptiles, all of which are preserved in acid resistant nodules and thus present considerable problems of preparation. They appear on initial investigation to be two or three species of lepidosaurian reptile and are provisionally allied with the Paliguanidae (Fig. 2), or short skulled eosuchians, other members of which have been described from South Africa[2,3] and Central Asia[4]. It seems that, apart from the glaring absence (so far) of any trace of the Synapsida, a vertebrate fauna similar to that found in other southern continents did exist in the Lower Trias of Australia, and it is to be expected that a further search will produce more material.

Sperm Transfer by Spermatophores in *Glossina austeni* Newstead

SPERMATOPHORES have apparently never been reported from higher flies. Davies[1] named three nematocerous families that have spermatophores, and more recently Downes[2] added a probable fourth to the list. Here I describe the spermatophore of *Glossina austeni* (Muscidae, Cyclorrhapha), and briefly discuss the implications of the discovery for current experimental techniques of studying *Glossina* reproduction.

Female flies were 2–4 days old when used for the mating studies, and males were at least 10 days old; observations were made at 25° C. To obtain mated flies, virgin pairs were left undisturbed in glass tubes for 24 h.

The spermatophore is a prominent colourless object in the uterus of recently mated females (Fig. 1). A typical example measured 700 × 500 × 400 μm, but the size varies. By microscopical examination of fresh and fixed specimens, a single closely packed sperm mass is easily seen inside the transparent body of the spermatophore; the mass can be dissected out whole from the surrounding material even when fresh. When viewed through the microscope, sperm are active in spermatophores placed in saline solution. The part of the spermatophore in immediate contact with the rounded sperm mass appears more transparent than remoter parts and is firmer in consistency. It keeps its shape even after the sperm mass is dissected out, but breaks easily on compression. As shown in Fig. 1, the spermatophore and the sperm mass are visible through the uterus wall.

Spermatophores are found adhering to the antero-dorsal wall of the uterus, and project backwards into the uterine cavity to an extent depending on spermatophore size. At this point on the wall is the opening of the fused spermathecal ducts.

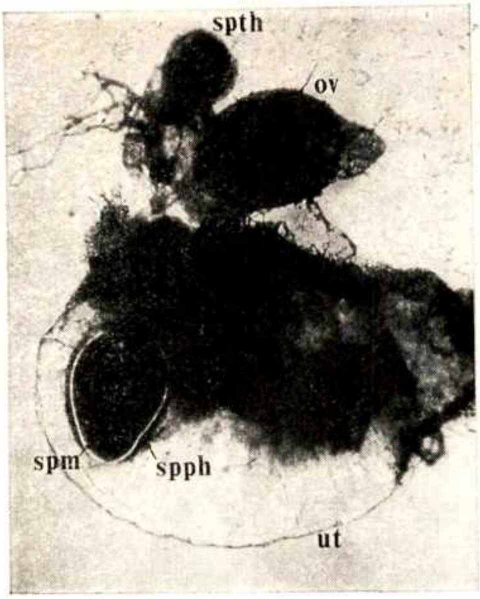

Fig. 1. Photograph of the reproductive system dissected from a recently mated female *Glossina austeni*, showing a spermatophore within the uterus. Lateral view (×25). *Ov*, ovary; *spm*, sperm mass; *spph*, spermatophore; *spth*, spermathecae; *ut*, uterus.

Some dissections of fixed, recently mated female flies have yielded a sperm mass bearing a bifid process that has precisely the shape of the sphermathecal ducts, showing that the sperm mass, though otherwise completely enclosed within the spermatophore, is placed exactly at the entrance to the common spermathecal duct. Whether the bifid process is made of the cuticular lining of the ducts or of fixed material taken intact from within them is not yet known.

Because the accessory glands of the male are partially exhausted after mating, it is reasonable to assume that at least the bulk of the spermatophore is of male accessory gland secretion, though the possibility that the female makes some contribution cannot be ruled out.

Most inseminated females dissected within a few hours of mating were found to have a spermatophore in the uterus, but some had none. To find out what happens to a spent spermatophore, fifty pairs of flies were set up in glass tubes and examined the next day, when twenty-nine tubes were found to contain expelled spermatophores. The spermatophores were somewhat shrunken but rapidly swelled to nearer normal size when placed in water. They contained considerable quantities of sperm; I noted also that spermatophores dissected from the uterus often contained more sperm than could evidently be accommodated within the spermathecae of the recipient female.

It seemed reasonable to suppose that the presence of an expelled spermatophore showed that the female concerned had been inseminated. This idea was tested by dissection, when it was found that all twenty-nine female flies had sperm in the spermathecae. It is worth recording that in two of these females spermatophores were also found in the uterus, showing that sperm transfer may occur twice between the same pair of flies within 24 h. The other twenty-one females were also dissected; eleven had spermatophores in the uterus and, of these, ten had sperm in the spermathecae, with one doubtful case. The remaining ten females had neither a spermatophore in the uterus nor sperm in the spermathecae. There was therefore an excellent correlation between the presence of a spermatophore in either the tube or in the uterus, and the presence of sperm in the spermathecae. I regard this as good preliminary evidence that the expelled spermatophore can be used to show that the female has been properly inseminated. On the other hand, the non-appearance of an expelled spermatophore after a day or two does not show failure of sperm transfer. Females tubed with males for 24 h and then isolated for another 24 h sometimes retained the spermatophore throughout the second period. Probably even these spermatophores would be expelled ultimately, but this point has not been verified.

The discovery of a spermatophore in *Glossina* has certain practical implications. First, the only current method for detecting whether a female has been inseminated (other than by breeding) is to dissect and examine the spermathecae for sperm content[3]. Empty spermathecae are taken to show that the fly is virgin. As already noted, the presence of an expelled spermatophore in the mating tube shows that sperm transfer has taken place, so that dissection is not necessary, and the female can be used for further studies. Second, I noticed that females dissected immediately after mating showed very few sperm in the spermathecae, though a full spermatophore was present in the uterus. There can be little doubt that in such cases sperm had not had time to migrate from the uterus to the spermathecae. Evidently, dissection of the females to determine their mated status would yield more information if the uterus were inspected as well as the spermathecae, especially when the latter seem to be empty.

Glossina morsitans was also found to use a spermatophore. A closer study of sperm transfer in other genera of advanced flies would perhaps reveal similar instances, for it is unlikely that *Glossina* is an isolated case. *Lucilia sericata* does not use one, and Khalifa[4] has listed species of Diptera in which he likewise failed to find spermatophores.

I thank Dr C. T. Lewis for his advice and encouragement, and Dr T. A. M. Nash, Tsetse Research Laboratory, Bristol, for the supply of tsetse flies. I also thank Professor T. R. E. Southwood for providing laboratory facilities and Mr R. H. Williams for taking the photographs. My study of mating in Diptera is supported by the Agricultural Research Council.

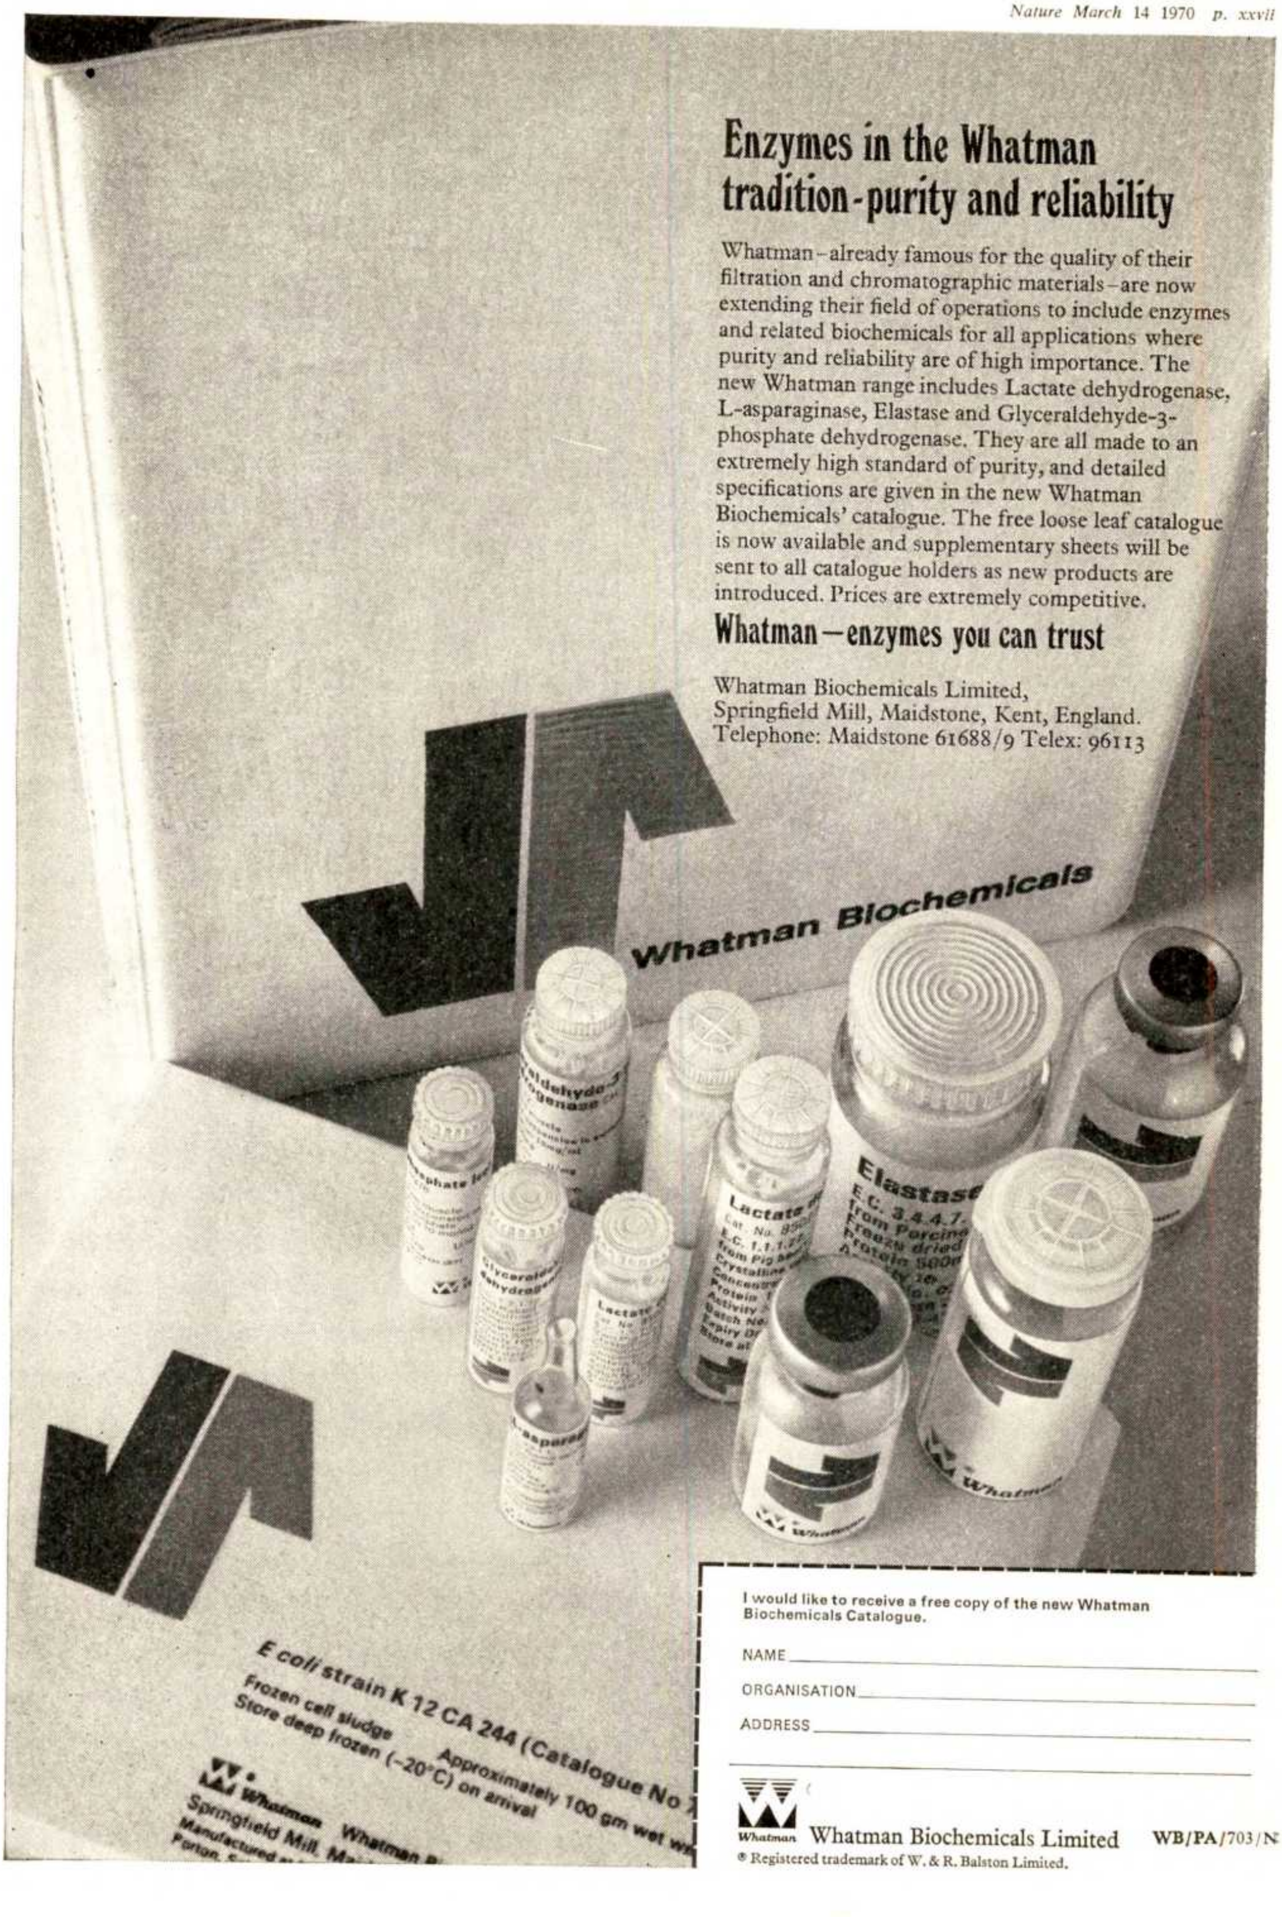
Courtship Behaviour of some *Drosophila melanogaster* Mutants

Hotta and Benzer (ref. 1), using loss of phototactic response as an indicator of defective vision in ebony^{11} and tan^{1} mutants of *D. melanogaster*, have shown that these mutants also possess abnormal electroretinograms (ERGs). Certain other body colour mutants, however, such as black, show normal ERGs, suggesting that body colour abnormality and defective ERG are unrelated. Pearce (now Crossley)[2,3] reported that the ebony gene influenced behaviour in a number of ways, not all of which could be related to defective vision. A more detailed analysis of the mutants studied by Hotta and Benzer is therefore of interest.

We have examined the behaviour of ebony^{11}, tan^{1} and black mutants kindly supplied by S. Benzer. The basis for comparison was ebony outcrossed flies (ebony^{0}) analysed previously[2,3] and the wild-type stock A which was used for outcrossing. Male behaviour was recorded on alternate beats of a metronome set at 80 beats/min. The numbers of single pair matings studied were 101 wild-type A; 91 ebony^{0}; 6 ebony^{11}; 17 tan^{1} and ^{10}black.



Enzymes in the Whatman tradition-purity and reliability

Whatman – already famous for the quality of their filtration and chromatographic materials – are now extending their field of operations to include enzymes and related biochemicals for all applications where purity and reliability are of high importance. The new Whatman range includes Lactate dehydrogenase, L-asparaginase, Elastase and Glyceraldehyde-3-phosphate dehydrogenase. They are all made to an extremely high standard of purity, and detailed specifications are given in the new Whatman Biochemicals' catalogue. The free loose leaf catalogue is now available and supplementary sheets will be sent to all catalogue holders as new products are introduced. Prices are extremely competitive.

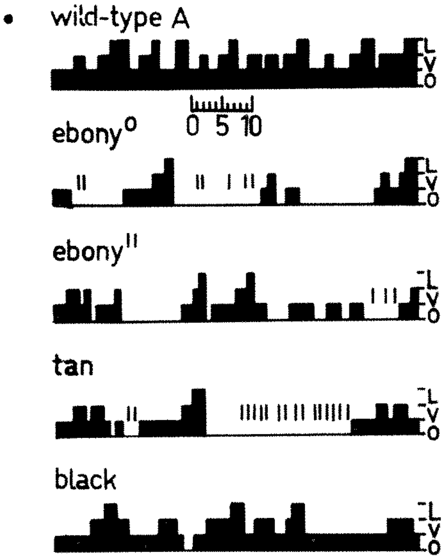

Fig. 1. Diagrammatic representation of typical courtships by different kinds of males courting their own females. Each sequence reads from left to right and the scale shows time units of 1·5 s. The height of shading indicates the courtship element being performed; the three levels are marked on the right (*L*, licking plus attempted copulation; *V*, vibration; *O*, orientation). Gaps in the records represent breaks in courtship. Wing flicks appear on the vibration row as vertical dashes.

Fig. 1 describes the courtship patterns recorded. Normal courtship is shown by wild-type A. The male first taps the female with his fore tarsi; he then faces her (orientation), and next extends one wing and vibrates it (vibration). During or after vibration he licks the female's genitalia (licking) and then attempts copulation. If this attempt is unsuccessful the sequence from orientation is repeated until copulation occurs. Black courtship pattern is essentially similar to that of wild-type A. The courtships of the two unrelated ebony stocks and tan^{1} are similar, but they differ strikingly from wild-type and from black. The main difference concerns breaks in courtship. These occur when a male ceases to follow a female or turns away from her. Wild-type males seldom break off courtship. Black males break off courtship more than wild-type but very much less than the other three forms studied. Another difference is that during a break ebony^{0}, ebony^{11} and tan^{1} males run in a zigzag path opening and closing their wings as they run (wing flicking). Tan^{1} males wing flick more than ebony^{0} and ebony^{11} males. Neither wild-type nor black males wing flick during breaks. Further analysis is incomplete, but the records so far suggest that, as in ebony^{0}, the courtship of these mutants contains fewer of the highly stimulating elements of vibration and licking than the courtship of wild-type A males. All the mutant males take longer to mate than wild-type males because of their inferior courtship. There are no obvious differences in female behaviour.

To what extent is the abnormal behaviour of ebony^{11} and tan^{1} related to defective ERG ? Behavioural observations suggest that courtship breaks occur because ebony^{0}, ebony^{11} and tan^{1} males do not use visual cues when courting. For example, all these males, unlike wild-type and black, make mistakes during courtship by licking and attempting to copulate with a female's head. The female then decamps and initiates a courtship break. Similarly, Crossley[3] showed that courtship of ebony^{0} males is uninfluenced by darkness but in contrast wild-type A males in red light (which to flies is darkness) behave as ebony^{0} males, making licking errors, breaking off courtship and zigzag running during breaks. The behavioural abnormalities shared by tan^{1} and ebony mutants probably stem, therefore, from impaired vision caused by changes in that part of the eye concerned with the ERG. Reduction in vibration and licking, however, is probably not the result of impaired vision, for ebony and tan mutants vibrate and lick in the dark and black, which has a normal ERG, also shows reduced vibration and licking. It is therefore unlikely that all the abnormal behaviour of tan and ebony mutants will be found attributable to their defective ERGs.

It is important to note that Rendel's[4] and Jacobs's[5] findings that ebony flies mate better in the dark than in the light are not supported here. Ebony^{0} did not mate better in the dark than in the light, so presumably selection of genes favouring improved mating in the dark had occurred in the stocks used by the earlier workers.

It may be concluded that certain courtship abnormalities are good indicators of impaired vision. Mutation may influence phototactic score or courtship behaviour or both without changing the visual system, for example, by changing activity. It is therefore suggested that in identifying behavioural mutants with defects in their visual system a more complete analysis than simple measurement of phototactic score is worthwhile.

Brassins—a New Family of Plant Hormones from Rape Pollen

WE report the discovery of new hormones, termed brassins, in rape pollen (*Brassica napus* L.). Following the general practice of designating gibberellins as plant hormones, we speak of brassins as hormones because they are specific translocatable organic compounds isolated from a plant and have induced measurable growth control when applied in minute amounts to another plant.

The chromatographic methods we used in purifying hormones from rape pollen were as follows: 1·5 g of finely ground air-dried rape pollen was extracted with 18 ml. of anhydrous ether for 30 min at room temperature. Decantate from this extraction was reduced in volume (40° C) and the concentrate was streaked across a 20 × 20 cm silica gel chromatographic plate 2 mm thick (Brinkmann). The plate was developed in benzene–methanol–acetic acid (45 : 8 : 4). The zone containing activity was located with the second internode assay[1] and visualized by spraying the plate with a 10 per cent alcoholic solution of phosphomolybdic acid followed by 15 min at 100° C. A zone of silica gel containing the activity (bounded by R_f 0·35 and 0·45) was removed, ground and put in a centrifuge tube with 10 ml. of absolute ethyl alcohol. We used the alcohol to avoid formation of condensation products[2]. The silica gel was stirred with the alcohol for 30 s at room temperature and separated by centrifugation, and the decantate was recovered. The extraction process was repeated and the second decantate added to the original one. The combined decantate was evaporated to dryness (40° C) in an evaporating dish. The residue was dissolved by swirling repeatedly five small portions of anhydrous ethyl ether (0·2–0·4 ml.) one at a time. The volume of the five combined extractions was reduced and the sample spotted across half the width of a silica gel plate of the type used before. The plate was developed with isopropyl

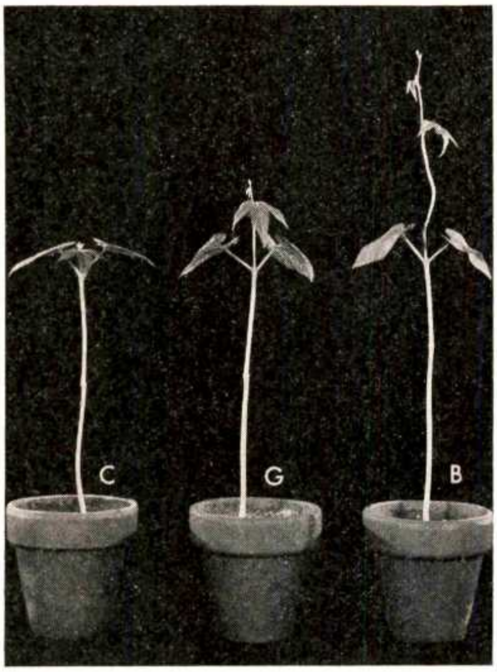

Fig. 1. Elongation of plants treated in the second internode assay with 10 μg of brassins (*B*); 0·001 μg of gibberellic acid (*G*); and the fractionated lanolin carrier alone (*C*). Duration of treatment 4 days.

ether and acetic acid (190 : 10). The activity remained at R_f 0·0. Silica gel in a zone that extended approximately 2 mm on each side of the zero R_f line was removed and extracted with absolute alcohol as described. The purified extract was evaporated to dryness, subjected to vacuum to remove traces of solvents and stored at 4° C for further studies.

The oily product obtained, termed "brassins", was assayed by the bean second internode test. Collectively the brassins induced very marked elongation of both second and third internodes of the intact plants when applied at the rate of 10 μg per plant. For example, second internodes grew an average of 155 mm during four days immediately after treatment, while controls treated with the fractionated lanolin alone grew only 12 mm. During nine days immediately after treatment, the third and fourth internodes grew an average of 8·9 and 11·7 times respectively more than the controls (Fig. 1). Further, the response to brassins was histologically different from the response induced by gibberellic acid.

The nuclear magnetic resonance spectrum of the brassins in deuterochloroform exhibited a pattern characteristic of fatty acid esters. The signals from internal tetramethyl silane (delta scale) appeared at 0·9 for a terminal methyl group split into triplet; a strong CH_2 (straight chain) absorption at 1·26, as a singlet; and other CH_3, CH_2 groups attached to the double bonds at 1·55 and 2·0 p.p.m., respectively. The resonance signal at 3·8 denoted the CH_2 attached to oxygen and the olefinic protons showed a multiplicity character at 5·3 p.p.m. There seemed to be no exchangeable protons, suggesting the absence of carboxyl and hydroxyl groups. The appearance of absorption at about 3·8 p.p.m. suggested that the brassins have a glyceride structure.

Analysis of the brassins by combined gas chromatography and mass spectrometry showed that the product contained several components with molecular weights ranging from 250 to 580. As well as the fragmentation of long chain hydrocarbon derivatives, we observed two characteristic and intense peaks at m/e 259 and 577 for two components. Furthermore, separations by 'Sephadex *LH*-20' gel chromatography with methylene dichloride resulted in five products that could be distinguished by ultraviolet absorption at 254 nm[3,4]. Each fraction proved to be active.

Strong ultraviolet absorption at 207 and 226 nm suggests unsaturation in all the components. Our data show that brassins are a family of new plant hormones that appear to have a glyceride structure.

We are investigating the fractionation of the five-component family of brassins and the structural determination of each compound. We did not determine a dosage response curve using the brassins collectively, for data based on response to the entire family of compounds would have relatively little meaning compared with response curves obtained from individual components of the brassin family.

Fats and similar compounds have been reported to control plant growth in some conditions (refs. 5, 6 and bibliography in ref. 6).

Pollen from plants other than rape may also contain hormones that are similar to brassins. For example, pollen from alder, *Alnus glutinosa* (L). Gaertn., was extracted and chromatographed as described above along with a parallel sample of pollen from rape. After simultaneous development in the same tank both plates showed similar fluorescence. The activity of these bands was typical of that obtained from all previous tests with brassins. The hormones obtained from alder and rape pollen thus seemed similar when compared biologically and chromatographically. Because the alder pollen was hand collected and not taken from bees, the brassins must be of plant origin.

We thank Marjorie E. Drowne and Bruce A. Sidwell for help with chromatographic separations; Norman E. Beckett for growing the necessary test plants; and L. N. Standifer, S. E. McGregor, and C. B. Reed for providing pollen.

Localization of Antigens associated with the Pollen Grain Wall by Immunofluorescence

MUCH of the protein detectable in short-term leachates from intact pollen grains[1] is probably released from the inner layer of the wall, the cellulosic intine, where protein and enzyme activity have been detected by cytochemical methods[2,3]. Extracts from intact grains are usually used in tests for pollen allergenicity, and we have considered the possibility that the proteins principally responsible come from the wall sites and not from within the cells. We report here the results of a study of the antigens present in leachates in which we have shown by immunofluorescence that they are indeed contributed largely from the intine and other wall locations.

We tested pollen from *Gladiolus gandavensis* Van Houtte cv. and *Ambrosia trifida* L. Earlier work showed that the relative thinness of the exine of gladiolus pollen facilitated the detection and localization of intine held proteins; *Ambrosia* (ragweed) pollen was selected for test because of its importance as a human allergen in the United States. The gladiolus pollen was taken from fresh flowers and partly dried at 2°–5° C, and that of ragweed was obtained from Greer Drug and Chemical Corp. One gram samples of intact pollen were extracted with 4–8 ml. of 0·85 per cent NaCl, adjusted to *p*H 7·5, in roller tubes for 24 h at 2° C. Rabbits were immunized with freshly prepared extracts in complete Freund adjuvant. Serum was collected on day 28 after three weekly injections. Double diffusion in agar showed that the extracts contained several antigens, and at least seven bands could be distinguished on immunoelectrophoresis. Faint cross-reactions occurred between the two pollens, but most of the antigenicity seems to be species specific.

30 min at room temperature, rinsed in buffer and mounted for observation with the fluorescence microscope.

RITC-labelled goat anti-rabbit globulin (7S fraction) was used in the indirect method. Samples of the unlabelled unfractionated or partly purified pollen leachate antisera were layered on to cryostat-cut sections, and the preparation incubated at room temperature for 30 min. The excess serum was then removed by rinsing with saline for 5–10 min, and the RITC-labelled goat anti-rabbit serum (globulin concentration, 1·5–2·0 mg/ml.) spread as before and left for 30–60 min at room temperature. The slides were then rinsed thoroughly with buffer and mounted. Control sections received RITC-labelled rabbit anti-guinea-pig serum direct, or rabbit anti-guinea-pig serum followed by RITC-labelled goat anti-rabbit serum.

Both methods gave good localization of antigens in the sectioned grains with appropriate antisera, but specificity was higher with the indirect technique. The clarity of the intine localization in gladiolus can be seen in Fig. 1. In the more complicated wall of ragweed pollen the intine was also labelled, and there was some indication of concentration of antigens at the apertures.

Immunofluorescence gave little evidence of antigens outside of the exine of gladiolus pollen, but the surface materials of ragweed pollen did give a reaction. These are derived from the tapetum, and are therefore products of the diploid parent and not of the haploid spores. The sporophytic origin of some of the antigens borne by the mature pollen grains was indicated also by a reaction between the tapetal plasmodium and labelled ragweed pollen–leachate antiserum in young anthers sectioned before maturation of the wall.

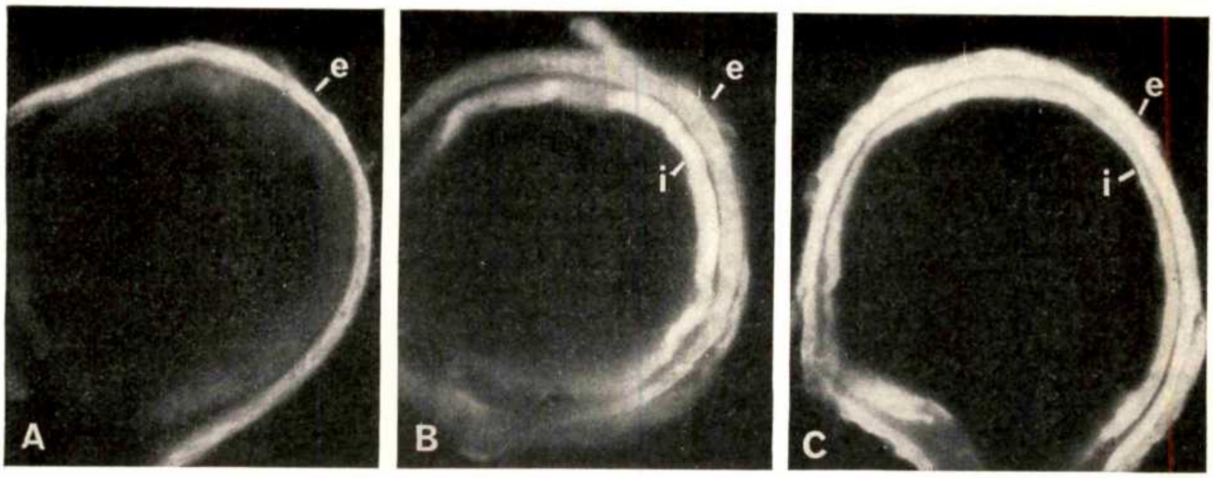

Fig. 1. Fluorescence photomicrographs (Bausch and Lomb 7–37 excitation filter, T2 barrier filter) of sections of unfixed pollen grains of *Gladiolus gandavensis* cut at −15° C. *A*, Control, treated with RITC-labelled rabbit anti-guinea-pig serum. The exine shows native fluorescence (*e*); the intine is barely visible. *B*, Direct method, RITC-labelled rabbit anti-gladiolus pollen–leachate serum. The exine shows native fluorescence, and the intine (*i*) is now heavily labelled. This section is not equatorial so that the thickness of the wall layers relative to the lumen is exaggerated. *C*, Indirect method, unlabelled rabbit anti-gladiolus pollen–leachate serum followed by RITC-labelled goat anti-rabbit globulin serum. Again the intine is heavily labelled. The micrographs were made from original colour transparencies in which a distinction could be made between the greenish fluorescence of the exine and the orange–red fluorescence of the RITC-labelled precipitins. Protoplasm is present in all three grains illustrated, but its fluorescence was too slight to be apparent in these prints. × *c*. 950.

The antibody globulin was partly purified with ammonium sulphate[4], and the concentration was estimated by absorption at 285 nm against a bovine γ-globulin standard. The concentration was adjusted to 10–20 mg/ml. for use. The most commonly used label, fluorescein isothiocyanate, proved unsatisfactory because its fluorescence matched the natural fluorescence of the exine too closely. Rhodamine B isothiocyanate (RITC) (Nutritional Biochemicals Corp.), which gives an orange–red fluorescence, provided better contrast.

Both direct and indirect methods of antigen localization were used. For the former, the labelling method of Cherry *et al.*[5] as modified by Goldman[4] was adopted. For use in controls, rabbit anti-guinea-pig serum was labelled in the same manner as the pollen diffusate antisera.

Pollen grains were sectioned in a cryostat to minimize loss of diffusible material[2,3], and the sections were brought quickly up to room temperature. The labelled antiserum, full strength or diluted with 0·02 M phosphate buffer at *p*H 6·5, was pipetted on to the sections and spread rapidly. The slides were then incubated in a moist atmosphere for

Various enzymes—for example, acid phosphatase and ribonuclease—are common to the intines of the pollens of gladiolus and ragweed[2,3]. The mixture of antigens present in leachates presumably includes these enzymes, but it remains possible that some of the wall-associated antigenic material is concerned with incompatibility reactions.

In emphasizing the wall sites as the source of the rapidly leached antigens, we do not suggest that saline extraction does not release proteins and other materials from within the vegetative cell of the pollen grain, but merely that these may not contribute very greatly to the total antigenicity of extracts.

Hydramoeba hydroxena (Entz) discovered on *Hydra graysoni* sp. nov.

While a population of hydras from the outflow of Hodson's Tarn in north Lancashire, England, was being examined, several specimens were observed to be parasitized by *Hydramoeba hydroxena* (Entz). A full taxonomic description has been compiled for the hydra concerned. It is to be called *Hydra graysoni* and is closely related to the group of hydras which possess a plano-convex embryotheca[1]. Although the hydras were examined periodically since September 1968, it was only in November 1969, when they went into a depression after 3 weeks in the laboratory, that the amoebae were discovered.

The amoebae were examined both live and after staining with iron haematoxylin. They generally resemble *Hydramoeba hydroxena*, as described already[2-5], and most closely resembles Ito's description, particularly in size and nuclear detail (Fig. 1). When at rest on the tentacles or column of the hydra, the so-called verrucosa-type[5] varies from 36 to 65 µm long. When detatched from the host the proteus-type[5] varies from 52 to 144 µm long. After being detached for a few minutes the proteus-type often turns into the limax-type[5], which varies from 90 to 220 µm long. Up to two nuclei have been observed, although only one is usually present. This is spherical and ranges from 8 to 17 µm in diameter. Polygonal crystals present in the cytoplasm vary from 1 to 3 µm across and granules can be seen which are up to 1 µm in size. Up to two contractile vacuoles have been seen, although there is usually only one, which is up to 23 µm in diameter.

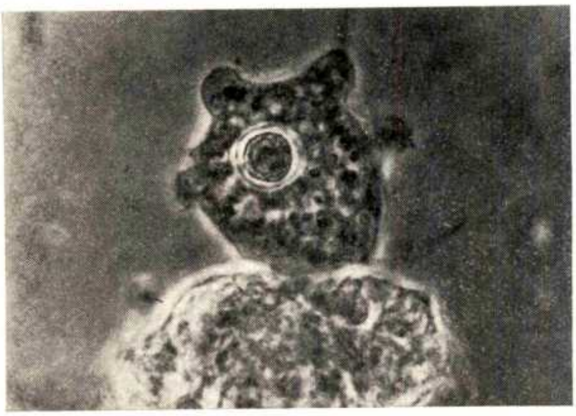

Fig. 1. A stained specimen of *Hydramoeba hydroxena* on the tip of a tentacle of *Hydra graysoni*. (× 500.)

This amoeba has been found to be a serious pathogen on several different species of *Hydra*. Infection experiments were carried out in culture water, *p*H 7·5 – 7·8, at 20° C. The hydras were not fed during the course of the infection. *Hydra graysoni* and *Hydra oligactis* (Pallas) died within 3 days. *Chlorohydra viridissima*, *Hydra pirardi* and *Hydra littoralis* died within 4 days. *Hydra pseudoligactis* died within 5 days and *Hydra vulgaris* (Pallas) was the most resistant to the parasite, surviving for 12 days. Many hydra populations have been examined from all over Britain by myself and my colleagues, and Hodson's Tarn is the only place, except for Esthwaite Lake[6], where *Hydramoeba hydroxena* has been found. The amoebae from both these localities are morphologically identical.

Umbellulidae Distribution extended in the Atlantic

On a recent Atlantic cruise of the USNS Kane, 1,540 exposures of the sea bed were obtained at 77 stations (Fig. 1). The Alpine multi-exposure camera system that was used consisted of a 35 mm camera fitted with a 33 mm *f*/11 Hopkins water corrected lens actuated by a bottom contact switch. At a typical station, twenty contacts would be made in the course of an hour, at locations varying with the drift of the ship.

The most remarkable forms of life photographed were organisms of the Phylum Cnidaria (Coelenterata) Family Umbellulidae (Fig. 2). Umbellulidae have previously been reported from the Atlantic by the Challenger Expedition (1873–1876)[1]. Dredged samples from this expedition form the basis for knowledge of the species of this family.

The basic appearance of the Umbellulidae is shown clearly in Fig. 2. The tall slender stalk (estimated height 1 m) is topped by a cluster of large flower-like polyps. The polyps are deep red, shading towards orange-red or purplish-red, each with eight long pennate tentacles[2,3]. The tentacles are used for feeding and defence. The base of the Umbellula is a long, hollow, muscular bulb which embeds itself into the soft-mud bottom and anchors the animal colony to the ocean floor[2,3].

Specimens of Umbellulidae have been found[2,3] at depths of 3,400–5,000 m. Fig. 2 comes from the lower continental rise of Africa at 05° 08·7′ N, 18° 06·5′ W at a depth of 5,300 m. Other stations that gave Umbellulidae sightings are shown in Fig. 1.

The sea floor at the camera station of Fig. 2 is fairly smooth. There are many scattered holes and small oblate mounds with a poorly developed bottom lineation. Occasional holes are distinguished by irregular groove patterns radiating from the centres. A sediment core taken at the camera station reveals the top 20 cm to be a greyish-brown fossiliferous lutite. The bottom water temperature is 1·78° C (unpublished results of B. C. Heezen and W. Fedukowicz). Other Kane camera stations that gave Umbellulidae sightings reveal a similar ocean bottom.

In Fig. 2 the specimen seems to be standing vertically, because of the camera's angle. A subsequent exposure

taken from a side view shows that the colony or specimen is leaning toward the camera at an angle of about 30°. The lean or bend probably results from the weight of the large cluster of polyps at the top. According to compass observations, the Umbellula is leaning to the west, perhaps showing bottom current movement in the area. The photograph gives no information about the current, although water movement must be present to sustain life processes.

The Kane photographs have extended the known range and concentration of the family Umbellulidae in the Atlantic.

I thank Mr L. Johnson for his help and technical assistance; Mrs R. Carson at the Smithsonian Oceanographic Sorting Center for identification; and Captain J. McCandless, the crew of the USNS Kane and participating NAVOCEANO personnel.

Isotopic Evidence for Diminishing Supply of Available Carbon during Diatom Bloom in the Black Sea

PLANKTON samples taken during the cruise of R/V Atlantis II in the Black Sea during March and April 1969 were analysed for their $^{13}C/^{12}C$ ratios. The results showed that over a large area of the Black Sea the plankton had uniform $\delta^{13}C$ values near -23 parts per 1,000. A sample from a very pronounced diatom bloom, however, was enriched in ^{13}C by 1·5 parts per 1,000. This isotopic shift was apparently produced by the organisms' accelerated carbon fixation which had decreased the available supply of inorganic carbon.

Samples were collected at seven stations (Fig. 1) with vertical tows of an open No. 2 net (mesh aperture 0·366 mm) through the upper 100 m of water. Although the net is designed primarily for zooplankton, appreciable amounts of phytoplankton were present in all samples. The samples were treated with dilute hydrochloric acid to remove carbonate and combusted to CO_2 in a vacuum line similar to that described by Craig[1]. The isotopic analyses were carried out on a high-precision isotope ratio mass spectrometer[2]; reproducibility of the entire procedure is $\pm 0{\cdot}1$ parts per 1,000. The analytical results together with other pertinent data on the samples and stations are shown in Table 1. $^{13}C/^{12}C$ ratios are reported in the δ-notation* and are relative to the PDB standard[3].

$$^{*}\delta^{13}C\ (^{0}/_{00}) = \left(\frac{(^{13}C/^{12}C)\ \text{sample})}{(^{13}C/^{12}C)\ \text{standard}} - 1\right) \times 1{,}000$$

* Order-of-magnitude estimate of the volume ratio zooplankton/phytoplankton in the fresh sample.
† Zooplankton separated from very large sample of diatom bloom.

After a first inspection of the data it was noted: (1) There is a remarkable uniformity in the δ^{13}C values of plankton over great parts of the Black Sea. The average value near −23 parts per 1,000 is typical for plankton from cold waters of a *p*H near 8·0 and relatively high content of free CO_2 (ref. 4) if the δ^{13}C of the total dissolved inorganic carbon lies near 0 parts per 1,000 (column 8 of Table 1). (2) With the exception of the samples from Station 1442 the varying ratio of zooplankton to phytoplankton does not affect the value of δ^{13}C—this has also been observed by others in the Atlantic and Pacific Oceans[5,6]. (3) There may be a significant difference in δ^{13}C between the sunset and sunrise tows at Station 1445. The difference is in the direction to be expected from the isotope fractionation between respired carbon and cell carbon[7].

The δ^{13}C values obtained on the plankton from Station 1442 are most interesting. The total yield of this tow was approximately 100 times that of all others. Although there were no apparent signs of it at the surface, there was a strong bloom of *Chaetoceros curvisetum* in the upper 100 m. The composite sample which contained a maximum of 1 per cent zooplankton gave a δ^{13}C value of −22·0 parts per 1,000. Zooplankton alone (almost all of which was *Calanus* sp.) yielded a δ^{13}C value of −23·3 parts per 1,000, identical to most other composite samples. In contrast, pure phytoplankton from this sample had a value of −21·8 parts per 1,000.

The greater ^{13}C content of the phytoplankton can best be explained as being caused by the high demand of carbon during the bloom. Because the cells cannot directly utilize the much more abundant bicarbonate, their carbon demand must be met by the dissolved free carbon dioxide which is continuously replenished through shifts in the equilibria of the aqueous carbonate system. As the rate of carbon fixation by photosynthesis approaches and eventually surpasses the rate of isotopic equilibration in the process of generation of new carbon dioxide, the fractionations between the cell carbon and the carbon dioxide and between the carbon dioxide and the bicarbonate decrease[4]. While the total carbon supply does not limit the development of the bloom here or in any other marine situation encountered[8], these results are an example of a natural situation in which the carbon demand of a developing algal bloom significantly decreases the supply of free carbon dioxide available for photosynthesis.

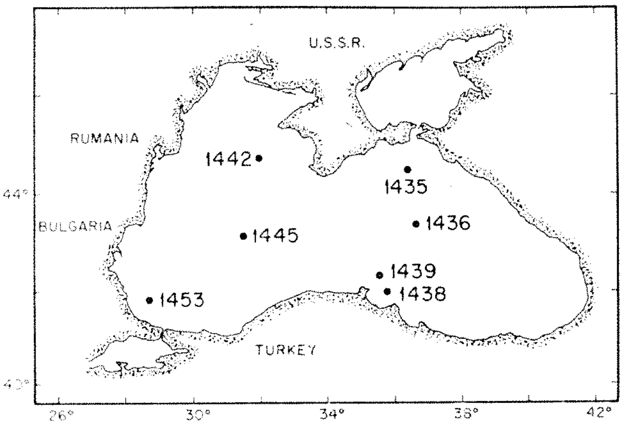

Fig. 1. Locations of plankton tows in the Black Sea.

The fact that the carbon of the zooplankton associated with the phytoplankton bloom is lighter by 1·5 parts per 1,000 can be attributed to the brevity of a diatom bloom relative to the time required for a complete metabolic turnover of the cell carbon in the zooplankton[8-10]. At the time of the sampling, the bloom had apparently not existed for a sufficient length of time to have allowed complete isotopic "assimilation" by the zooplankton. The carbon isotope content of the grazers was still similar to pre-bloom conditions typical for the Black Sea as revealed by the other samples analysed by us.

This inference was checked by an order of magnitude calculation. The carbon content of the catch was 2 g (30 per cent of dry weight). The volume of water which went through the net was estimated at 4 m^3 and contained about 160 g total inorganic carbon in solution. Of this carbon, roughly 2·5 g was free carbon dioxide (calculated using data of Alekin[11] and extrapolating values of Buch[12] and Saruhashi[13] to 10·2 parts per 1,000 chlorinity at 7·2° C and a *p*H of 8·0). The amounts of cell carbon and inorganic carbon available for photosynthesis were thus similar in the volume of water occupied by the bloom. Even with conservative estimates for the generation time of cells, in the advanced stages of the bloom the free CO_2 in the water must have been replaced at least once a day through the steps of association and dehydration or through direct dissociation of HCO_3^- ions. From values of Buch[14] one may extrapolate that it takes several minutes for these steps to proceed to 90 per cent completion in Black Sea conditions. Reaction rates for isotopic equilibria, however, are lower by orders of magnitude and the δ^{13}C of the newly formed carbon dioxide is bound to be greater than its equilibrium value of −8 parts per 1,000 at the prevailing temperature[15]. The dynamic situation of a bloom of this magnitude thus precludes isotopic equilibrium and results in an isotope content of the cells which is significantly closer to that of the inorganic carbon pool.

I thank Drs G. D. Grice and E. M. Hulburt for identifying the plankton and Dr R. R. L. Guillard for making a cell count on sample P-6. Mrs E. Ross provided valuable laboratory assistance. This work was supported by the US Office of Naval Research and by the US National Science Foundation.

Volatile Factor in Soil Fungistasis

SOIL fungistasis was originally described by Dobbs and Hinson[1] as a widespread phenomenon in which viable fungal spores were unable to germinate in natural soil. Although no precise and universally accepted explanation for this phenomenon is available, fungistasis is usually considered to result from biological activity in soil[2,3]. Failure to extract an inhibitory factor[5-7] has led to the nutritional theory[2,3] that the phenomenon can be explained wholly by the lack of nutrients essential for germination in the soil micro-environments of fungal spores. On the other hand, some have suggested that there are inhibitors in soil, the effects of which are nullified by the addition of suitable nutrients[4,6,8,9]. We report here evidence of a volatile factor in soil which induces fungistasis.

Three assay methods were used in a comparative study of volatile and diffusible fungistatic factors. First, the sterile 'Cellophane' agar diffusion method[10] (SCAD) was used: agar disks (8 mm in diameter and 5–6 mm thick) were placed on a sterile 'Cellophane' membrane in contact with 50 g of soil in a Petri plate. The disks were pre-activated in this manner for 24 h at 28°–29° C, transferred to another slide on a glass rod support in a sterile moist plate, and inoculated with a conidial suspension (150–200 conidia/field × 100) of a test organism. After 22–24 h at 25° C, agar disks were examined and germination of spores was recorded. Second, the soil emanation agar method (SEA) was used: the procedure was the same as the previous method except that there was no direct contact between soil and disks, which were placed on a sterile glass slide in a covered Petri dish containing 50 g of soil for pre-activation. Third, a direct assay method (D) was used: washed 'Millipore' filters were impregnated with a test conidial suspension (200–250 conidia/field, × 100) and inserted into tumblers of soil. The filters were gently removed after incubation, stained with lacto-phenol–cotton blue mounting medium, and examined for spore germination. Controls consisted of incubation of agar disks (for the first two methods) or 'Millipore' filters (for the direct method) without soil but otherwise in identical conditions. All tests were conducted in duplicate and repeated several times.

Some characteristics of soils collected from various localities in Colorado and stored air-dried before use are shown in Table 1. At the beginning of the experiment, soil was moistened to 60 per cent water-holding capacity and tests for fungistatic properties were carried out 1, 4, 7, 10 and 15 days later.

Only four of the twenty different fungi isolated from soil are discussed here, because their responses were representative of the species tested. Data obtained 10 days after soil had been moistened are omitted because results were intermediate to those collected after 7 or 15 days. Uninoculated agar disk controls in contact with 'Cellophane' (SCAD method) or on slides (SEA method) remained sterile at the end of the assay periods.

Results are given in Fig. 1. There have been conflicting views on the effect of soil *p*H on spore germination[7,10,11]. Our studies indicate a profound effect of *p*H (especially in recently moistened soils), for germination in all assays was highest in acid or neutral soils and lowest in alkaline soils.

In general, assay by the first two methods revealed a high percentage of germination in soil 1 day after moistening and declined thereafter, confirming earlier observations[1,12]. The spore germination after 1 day, as determined by the direct assay method, gives an indication of the direct effect of *p*H, for nutrients contributing to activity would be available[2,7].

Contact with soil was not necessary for inhibition of spore germination. The soil emanation agar method clearly showed reduced germination of spores, particularly when exposed to alkaline soils, thereby indicating the presence of a volatile inhibitory factor. Inhibition curves as measured by the first two methods were approximately parallel. A decline and steady state of inhibition by the volatile factor reached after 10–15 days probably resulted from the decrease and subsequent equilibrium of microbial activity in moistened soils[13]. Volatiles have been suggested[14] as fungistatic substances, but results of tests have proved negative[7]. Data shown in Fig. 1 demonstrate why this was true. Although inhibition in the soil emanation agar method was detected with all test organisms, at specific times after moistening, at some values of soil *p*H, and with certain organisms, inhibition was not evident: for example, for *P. chrysogenum* and *T. viride* in acid soils 7 and 15 days after moistening.

Particularly in alkaline clay loam soils with a low content of organic matter, little spore germination was demonstrated by the soil emanation agar method. Preliminary tests with alkaline loam and sandy loam types of soils containing low organic matter, however, indicated the presence of a volatile factor but in lower concentrations, as reflected by relatively higher germination of spores. It is not clear whether the lighter soils tested, by virtue of their physical properties, provide less favourable environments for microbial activity or lack particular organisms capable of producing inhibitory volatile substances, or whether such organisms exist but are not very active in such soils.

This research constitutes the first direct evidence of a volatile inhibitory factor[15] in soil contributing significantly to responses of fungal spores in the fungistatic phenomenon.

We thank Drs William Kreutzer, L. W. Durrell, Gary Griffin and Penelope Hanchey for advice and useful

Table 1. SOME PROPERTIES OF SOILS USED IN ASSAYING OF FUNGISTATIC FACTORS

Soil *p*H	Soil type	Organic matter (per cent)	Lime (per cent)	NO_3-N (p.p.m.)	P_2O_5 (lb/acre)	K_2O (lb/acre)	DTPA extractable micro-nutrients Zn (p.p.m.)	Fe (p.p.m.)	Mn (p.p.m.)	Cu (p.p.m.)
4·6	Loam	5·8	< 1	—	300	210	10·00	40·0	—	—

L-Amino-acid Oxidase, a Bactericidal System

THE antibacterial activity of glucose oxidase[1-3] and xanthine oxidase[4,5] was reported twenty-five years ago. The antibacterial effect was attributed to the H_2O_2 generated during aerobic oxidation of an appropriate substrate. Considering the potency and broad spectrum of the antibacterial action of these enyzmes, it is surprising

Table 1. BACTERICIDAL ACTIVITY OF L-AMINO-ACID OXIDASE AGAINST PATHOGENIC STRAINS

Estimated LD_{50} (μg)	0·7	9·0	15·0	10·0	3·0	3·5	22·0	50·0

* In 1 ml. phosphate buffered saline (pH 6·9) containing mM L-leucine.

that attention has not been focused on them or on other flavoproteins as agents in host defence. In this report, the bactericidal action of L-amino-acid oxidase is examined.

L-Amino-acid oxidase (from *Crotalus adamanteus*), purified according to Wellner and Meister[6], D-amino-acid oxidase (electrophoretically purified), and catalase were purchased from commercial sources. Stock solutions of enzymes and certain other reagents were prepared in 5 mM phosphate buffer saline at pH 6·9 and sterilized by filtration through 0·45 μm membranes. All bacterial strains were recent clinical isolates; they were maintained on trypticase-soy agar before subculture in trypticase-soy broth. The bactericidal assay used in these studies is described elsewhere[7]. The bactericidal activity of the L-amino-acid oxidase system was evident to varying degrees against all strains tested. The bottom line in Table 1 gives an extrapolated estimate of the LD_{50} for each bacterial strain.

Other data demonstrate that the oxidase is labile to heating at 60° C, the optimum pH is between 6·5 and 7·0; 3 μg of the oxidase is capable of killing up to 10^6 staphylococci. Several experiments were tried to demonstrate the bactericidal effect by a D-amino-acid oxidase system. Different batches of the enzyme in amounts ranging from 1–100 μg were incubated with bacterial strains in the presence of 10^{-2} to 10^{-6} M concentrations of D-serine; no antibacterial activity was noted. The addition of either D-leucine or D-methionine (10^{-4} to 10^{-6} M) to the system also did not elicit an antibacterial effect.

Certain characteristics of L-amino-acid oxidase as determined by bactericidal assay (Table 2) were in accord with the established behaviour of the enzyme in conventional assays with amino-acid substrates. The enzyme was heat-labile, insensitive to 10^{-3} M KCN and inhibited by excess substrate (L-leucine). Catalase effectively inhibited the antibacterial activity, most probably by destruction of H_2O_2, the actual lethal agent. A small synergistic effect is noted when amounts of exogenous H_2O_2 are added to the oxidase at levels where each agent alone is not very lethal.

Table 2. EFFECT OF SOME REAGENTS ON THE L-AMINO-ACID OXIDASE BACTERICIDAL SYSTEM

Reagent	Amount or concentration	Per cent lethal action *M. aureus* (2 μg oxidase)	*S. typhimurium* (20 μg oxidase)	
None		100	94	
Catalase	1·0 μg	0	0	
	0·2 μg	21	0	
	0·1 μg	86	32	
	0·01 μg	100	82

KCN	10^{-3} M	85	93	
L-Leucine*	10^{-1} M	0	0	
	10^{-2} M	100	99	
	10^{-3} M	100	93	
H_2O_2	None	28		0·5 μg oxidase in this experiment
	10^{-5} M	96		
	10^{-6} M	36		
	10^{-5} M	24		H_2O_2 controls
	10^{-6} M	0		

* L-Leucine at the indicated concentrations was also incorporated into the agar medium for overnight incubation.

The fact that the L-amino-acid oxidase system produces a bactericidal effect, while the D-amino-acid oxidase system does not, raises the question of the site of action of the H_2O_2 produced during oxidation of amino-acid substrates. Because staphylococci produce catalase but are quite susceptible to the L-amino-acid oxidase system, an intracellular site of the action of H_2O_2 seems unlikely. Furthermore, the marked inhibition of killing by small quantities of exogenous catalase argues against an intracellular site. The tendency of D-amino-acid oxidase to polymerize[8] may interfere with its ability to approach sufficiently close to the cell to obtain a lethal concentration of H_2O_2, which suggests that peroxide sensitive loci exist on or near the cell membrane. Similarly, the lesser sensitivity of all smooth enteric strains to L-amino-acid oxidase may relate to a greater difficulty of the enzyme to penetrate through surface lipopolysaccharides. An alternative possibility would be that the bactericidal flavoproteins produce a toxic intermediate, that is a reduced form of oxygen other than H_2O_2, which is not produced in the non-bactericidal D-amino-acid oxidase system.

Iyer and colleagues[9] suggested that the formation of H_2O_2 within phagocytic cells may represent an important antibacterial defence mechanism. These authors and others[10] reported significant increases in H_2O_2 production during phagocytosis. The lack of increased H_2O_2 formation in phagocytosing granulocytes from patients with chronic granulomatous disease[11] may account, in part, for the inability of these phagocytes to kill certain bacterial strains[12,13].

Rossi and Zatti[14] reported a stimulation of an NADPH-oxidase activity in leucocyte granules following phagocytosis. Such a granule bound oxidase may constitute an important bactericidal system in which the enzyme is delivered directly to the phagocytic pouch containing bacteria. This mechanism would exclude inhibition of bactericidal action by catalase, a cytoplasmic enzyme[15]. Continuing studies indicate that rabbit neutrophilic leucocytes do contain an oxidase system with bactericidal properties.

Altered Cell Walls of *Staphylococcus aureus* resistant to Methicillin

METHICILLIN-resistant (MR) strains of *Staphylococcus aureus*, those capable of multiplying in the presence of 12·5 μg of methicillin/ml. (eight or more times that tolerated by methicillin-sensitive (MS) strains), are also resistant to other commonly used antibiotics, including other semi-synthetic penicillins and cephalosporins[1–7]. They can cause major disease[6–11] and thus may pose a serious therapeutic problem.

The mechanism of resistance to methicillin seems to be independent of penicillinase (β-lactamase) because MR strains grow in the presence of high concentrations of methicillin[7,12], and because variants which have lost the ability to synthesize penicillinase remain MR[10,13]. Thus the mechanism is grossly different from that by which most strains of *S. aureus* resist benzylpenicillin—by means of penicillinase[14–16]. For this reason, and because penicillins are known to act by interfering with normal cell wall formation[17–19], the possibility that methicillin-resistance might be associated with some alteration in cell wall composition was considered.

Table 1. SUSCEPTIBILITY OF *Staphylococcus aureus* TO LYSOSTAPHIN (L) AND METHICILLIN

Strains	Proportion MR	Rate of lysis by L, (Δ% T/h)	Ratio of rates of lysis, parent/MR clone	*MIC* of methicillin, (μg/ml.)
MR 1*a*	$4 \cdot 2 \times 10^{-5}$	45–287	5·7–8·4	⩾1,600
MR 1*b*	0·57–0·73	14–34		⩾1,600
MR 2*a*	$3 \cdot 1 \times 10^{-7}$	99–328	3·7–6·3	800
MR 2*b*	0·57	20–83		800
MR 3*a*	5×10^{-5}	85	3·1	800

MR 5*a*	$4 \cdot 5 \times 10^{-6}$	72	2·8	800
MR 5*b*	0·61	26		⩾1,600
MR Col. *a*	0·06	35	2·5	⩾1,600
MR Col. *b*	0·75	14		⩾1,600
60/1	0	53–165		6·2
Oxford 167	0	396		3·1

MR, Methicillin-resistant, naturally occurring; *a*, clone from antibiotic-free agar (parent strain); *b*, clone from agar containing 50 μg/ml. of cloxacillin; 0, none detected, that is $< 10^{-8}$ of cells in the culture; T, transmission of light at 500 or 620 nm; *MIC* = minimum inhibiting concentration after 48 h at 37° C.

Cell walls of naturally occurring MR *S. aureus* were compared with MS cells with respect to amino-acid composition and susceptibility to lysostaphin (supplied by Dr P. Tavormina, Mead Johnson Research Center, Evansville, Indiana). The amino-acids of acid hydrolysates of cell walls of populations of predominantly (37–75 per cent) MR cells were found to have essentially the same molar ratios of glutamate, lysine, alanine and glycine as those of MS cells.

The predominantly MR cell populations were obtained by cloning three different clinical MR isolates in the presence of 50 μg/ml. of cloxacillin. Eight different MS cell populations were studied: two naturally occurring MS strains and six parent strains from which the MS cell populations were cloned and which originally contained only 6 in 10^2 to 3 in 10^7 highly resistant cells, or colony forming units (c.f.u.). The proportion of "highly resistant" c.f.u. was determined by comparing the total colony count on medium free antibiotic with that on medium containing 50 μg/ml. of cloxacillin. The cells were grown for 19 h at 37° C in Difco brain–heart infusion (BHI), washed, disrupted with the MSK mechanical cell homogenizer using 0·1 mm glass beads[20]. The cell walls were separated by differential centrifugation[21,22] and hydrolysed with 6 M HCl at 105° C. Amino-acids in the hydrolysates were analysed in the Phoenix (Philadelphia) amino-acid analyser.

Rates of lysis of MR and MS strains of *S. aureus* by lysostaphin were compared by observing changes in light transmission at 500 or 620 nm of intact bacteria suspended in *p*H 7·4 Tris–NaCl buffer[23]. "Parent" strains of naturally occurring MR *S. aureus* contained only a minority (6 in 10^2–3 in 10^7) of highly resistant c.f.u.; they were lysed by lysostaphin 2·5 to 8·4 times as rapidly as were clones derived from them, which contained 37–75 per cent highly resistant c.f.u. (Table 1). This consistent difference in rate of lysis was taken as evidence that the cell walls or surfaces of MR cells were different from those of MS cells because the wall is the substrate for the lysostaphin[24,25].

The fact that no difference in amino-acid composition of MS and MR cells was detected by the method used suggests that the difference in the walls is not attributable to different peptide composition. But the data presented could be accounted for by difference in amino-acid sequence, or the presence of some non-peptide component that prevented access of enzyme to its substrate, the glycyl–glycyl bonds[24,25].

The observed difference in the cell wall or surface could be either the cause of the resistance to methicillin, the result of the resistance mechanism, or a coincidentally linked trait.

Methicillin-resistance *per se* is not invariably associated with decreased susceptibility to lysostaphin. Two MS strains which were "trained" to methicillin resistance by serial transfers in increasing concentrations of the antibiotic until they grew in 100 μg/ml. underwent little or no change in susceptibility to lysostaphin. Similarly, a strain of MS *S. aureus* selected for resistance to lysis by lysostaphin showed no significant change in its resistance to semi-synthetic penicillins.

Book Reviews

WHITHER THE BRITISH LANDSCAPE?

New Lives, New Landscapes

By Nan Fairbrother. Pp. viii + 397. (Architectural Press: London, February 1970.) 75*s*.

THIS book is about the changing environment, though chiefly about the countryside. In it, the author projects a mass of information about ecology, geology, sociology, geography, agriculture, land economics, planning and associated law, and a few other disciplines. Some of this is relevant and in context, some not. Some is accurate, some probably accurate, and some not so. The information supports a pragmatic and socially orientated plea for better landscape planning, and, as such, is more persuasive than aesthetic arguments only. The style of writing is varied. Some passages are scholarly and thought provoking, some casual and entertaining, some chatty and irritating. The mass of information, and the presentation, tend to obscure the essentials of the argument: certainly from the point of view of the professional and the administrator.

The text is interwoven (usually in bracketed asides) with a synopsis of the author's life history, presumably designed to demonstrate that she knows how most of the groups in society think about the environment. Poor little girl from urban slum goes to university, and holidays pre-war in the remoter hills and coastal regions of the UK. Wartime evacuee mum lived in uncomfortable muddy countryside, but now has a house in London, one in the country, and fits in holidays in the United States with the widening interests of a professional, but not practising, landscape architect. This may of course be more typical of modern society than I suspect. She is certainly methodical. Her card index of suitable quotes from other writers must be voluminous, and if she does not keep an index of "ideas about the countryside, and so on" (her style, not mine), she must have an excellent memory, for nearly everybody I have ever heard, good, bad or madcap, appears somewhere. Some sentences are positively arresting. "In popular (recreation) areas, however, the natural vegetation is no longer forest but people and cars. . . ."

In part one, "A New Society in an Old Setting", the history of our changing environment is reviewed extremely well. Though this lacks the scholarship of writers like W. G. Hoskins, the interpretation is rewarding in its simplicity, its realism and a freedom from nostalgia. As an explanation of why the environment is like it is and how we, the people of Britain, have made it so, it provides excellent background reading for those developing an interest in the environment.

Part two, "Landscapes for an Industrial Democracy", reiterates some of the arguments of the first part. It presents a thesis that in Britain we have moved into an era where there are four basic environments: "Built-Up Urban", "The Green-Urban", "The New Farming", and "The Man-Made Wild". Will this classification make an impact and come into general use? Has it the merit of more simplicity than "Urban", "Rural" and "Urban-Rural Fringe"?

Part three, however, "A Four-Point Plan for a New Landscape Framework", presumably the essence of the sermon, is unconvincing and naïve. Our exploding cities are to have an aesthetic "cordon sanitaire" of tree belts used chiefly for recreation. Elsewhere, in landscape regions identified on ecological criteria, we are to convince all those concerned with managing land to plant the truly native tree and shrub species, thereby achieving beauty and regional character. Of course, states Miss Fairbrother, this will not cost very much.

I find this an irritating book. Perhaps because this is European Conservation Year when interest in the environment should stimulate the market for books about it, the Architectural Press, or the author, or both, hurried too much. Whatever the intended market, the book would have been better if half the length, and with the chatter, repetition and biography edited out.

I also find it a disturbing book. The simplicity of the ideas is such that they do not leave the mind. Presumably few authors would ask for more, but the feeling remains that the book fails. Without part three and with a slight redraft of part two, it could be accepted as a popular interpretative work. With some ruthless editing, enrichment of the nature conservation content, a deeper understanding of land use and recreation planning and its organization (particularly in the context of new legislation and the proposed reorganization of local government), it could have been a more challenging and influential work.

Nevertheless it makes interesting reading. Nan Fairbrother quotes Frank Fraser Darling: "We can be of little service to our fellows until we become disillusioned without being embittered". Nobody reading this book can conceive that she is disillusioned; optimism and hope so dominate the presentation that she may be criticized for being too ready to accept change. Moreover, when a writer has sufficient humour, imagination, and indeed commonsense, to propose a society "For enjoying the countryside without feeling virtuous", readers may be sure that there is no evidence of bitterness in her work.

R. J. S. HOOKWAY

CHOICE IN EDUCATION

Decision Models for Educational Planning

By Peter Armitage, Cyril Smith and Paul Alper. (LSE Studies on Education, from the Higher Education Research Unit of the London School of Economics and Political Science.) Pp. ix + 124. (Allen Lane (The Penguin Press): London, December 1969.) 75*s*.

EDUCATIONAL planning is a fashionable exercise. It arises from the fact that education takes a big part of the national income—roughly 6 per cent of the gross national product in the United Kingdom—and all the signs suggest that it will continue to take a rising proportion of the GNP. This large and rising proportion of the GNP ought to be allocated in order to get the best results. In some ways, in the private sector, gross profit rates are the criterion that can be used for such allocation; in some public sectors, of which roads are an instance, an approximation to gross profit rates can be reached by the use of so called cost–benefit techniques. In other areas, of which education and health are instances, the criteria are far less quantitative. It is difficult to see why £100 million should go to universities rather than to primary schools.

In actual fact, big decisions like that rarely have to be taken. In any one fiscal year most expenditure is predetermined because the teachers and buildings are there and have to be paid for. Such margins as there are tend to be committed to certain overwhelming objectives of which the most important is extra pupils who just turn up and have to be taught.

But over the longer term strategic planning is possible. It is not necessarily inevitable to raise the school-leaving age. We are not obliged by ineluctable forces to offer a place in higher education to all who ask for one. These are, to some extent, affective choices.

On what basis, other than sheer whim or preference, can these choices be made? This book does not answer that question. What it does is to show how interrelated the educational system is and the range of choices that are restricted by making any one decision. They offer a range of choices to those who are seeking to influence policy.

The trouble is that our political processes do not favour ranges of choice. As I have said elsewhere, in connexion with this excellent book, which is clearly written and helpful, in a system where the Department chooses the highest figure and the Treasury picks the lowest figure, rational decision is hindered. But the techniques suggested here will be used more and more and ultimately will prove their own case.

JOHN VAIZEY

EDUCATION MANIFESTO

Education for Democracy

Edited by David Rubinstein and Colin Stoneman. (Penguin Education Special.) Pp. 220. (Penguin Books: Harmondsworth, Middlesex, February 1970.) 6*s*.

EVERYBODY, it seems, wants to hear how new techniques in education are producing a generation of illiterates. The Black Papers, arguing for a return to an unashamedly élitist education system, to preserve the standards which they allege are fast slipping away, have had most of the press coverage while publications defending progressive techniques have passed almost without comment. Such a fate is, however, unlikely to befall this book. If the impressive list of contributors does not ensure a wide audience for this manifesto on progressive education, its sheer readability should do so.

The book is a collection of essays bound together by the common belief that education should be designed to cater for all children, and that a system designed to produce élites is both socially unacceptable and educationally unsound. Most of the contributors make no secret of the fact that they see education as a means of reforming society. Arthur Rowe, for example, makes the point that the present education system, being closely tied to class structure, can only perpetuate a class ridden society, and this theme is constantly echoed in other essays. Another fundamental belief that keeps cropping up is a rejection of the Black Papers' thesis of innate intelligence. Lewis Cohen and Colin Stoneman, in a carefully argued essay, outline a theory of intelligence based on several independent factors, some, if not all, of which may be genetically determined but which need to be developed to their full. They argue that labelling 80 per cent of British children failures, and treating them as if they are unlikely ever to excel in anything, will certainly not develop their potential.

In the essays on primary education, the contributors closely follow the progressive themes of freedom and of learning through experience rather than through formalized teaching methods. John Mitchell argues that traditional authoritarian teaching methods are likely to suppress any desire in the child to find out things for himself. The child will consequently lack any originality of expression, and the whole learning process will become a chore.

The section devoted to secondary education is, of course, bitterly opposed to selection of any sort at eleven-plus. In particular, Peter Mauger argues that the present system came into being based on pseudo-psychological grounds that were not even held at the time it was introduced, and, because middle class children have an overwhelming advantage in the selection process, the system is class biased, élitist and anti-democratic. But, although Brian Simon presents a good, rational argument against streaming, this section lacks any thorough discussion of alternatives.

Higher education does not fare so well in this book. Although there is a plea for higher education for all who want it, and various allusions are made to the educational absurdity of the binary system, little direct discussion of the structure of the present system is given. But this may be more a product of the length of the essays than their intention. Throughout the book, brevity occasionally takes precedence over depth of argument, with the result that the essays sometimes seem rather superficial. But loss of depth is matched by readability and immediate assimilation, which should ensure that the progressive message should get across to a wide cross-section of people. In any case, it is a book which every serving or aspiring teacher can ill afford to miss.

COLIN NORMAN

BOYLE'S LIFE

The Life of the Honourable Robert Boyle, F.R.S.

By R. E. W. Maddison. Pp. xxii + 332 + 40 plates. (Taylor and Francis: London, October 1969.) 190*s*.

NOTED for his law of which he was not sole discoverer, and associated with an apparatus he did not invent, Robert Boyle is among the few scientists of the seventeenth century still popularly known. Having connexions in both of the warring parties in the Civil War, but of an apolitical cast of mind, he quickly became absorbed in the philosophical and utilitarian designs of the circle of men which revolved about Samuel Hartlib. This was not, however, to be his single absorbing interest; charitable work and religious contemplation were of equal, if not greater, importance, and should not be forgotten in the assessment of his scientific work.

His life divides conveniently into the three periods of prolonged residence at Stalbridge, Oxford and London; it was largely uneventful. In spite of the reduction of his time by persistent ill-health, by the demands for entertainment of a stream of foreign visitors (he seems to have been considered a scientific sight of London), and by a number of public appointments, Boyle produced a stream of religious and philosophical works which were constantly esteemed and acclaimed. He could usually be relied on by the Royal Society for an entertaining experiment and, with John Ray, was one of the most frequent contributors to early numbers of the *Philosophical Transactions*.

Of Boyle's importance there is no doubt. As John Freind put it in 1712, it rests in the fact that he "has not so much laid a new foundation of Chymistry, as he has thrown down the old". It would be foolish, however, to look to this book for an explication of this, for this is not Maddison's purpose. This is strictly and limitedly defined. In the absence of any study of Boyle based on the original sources since Thomas Birch published his in 1744, and from which all others derive, Maddison has set out to recount accurately the events of Boyle's life as a supplement to Birch, and to offer a guide to his diverse interests. The book is scholarly and antiquarian and is, as such, an unfortunate rarity in the history of science. It draws together a great amount of esoteric information on various aspects, and sets out the state of discussion, together with the available facts, at controversial points.

It is a pity the publishers have not bothered to attain the standards of printing accuracy, illustration reproduction and typographical design of many cheaper works. Ugly is the only word appropriate to its physical appearance. This, of course, does not affect its value as a quarry for other scholars (and not simply those interested in science), but illustrations properly integrated with the text would have increased its usefulness considerably. The general reader may well find it heavy going, especially the opening chapter, where the weight of Maddison's annotation will defeat all but the most indefatigable. Elsewhere, however, one wishes for rather more: the book's scholarly usefulness would have been surely greater if references to correspondence printed by Birch had also indicated the manuscript source where this is extant. Equally one sometimes wishes for more extended treatments of particular aspects (especially that of the Invisible College). Maddison assumes a great deal of background information in the reader of what is, none the less, a basic work.

A. J. TURNER

SOLVENT CHEMISTRY

Non-Aqueous Solvents

By T. C. Waddington. (Studies in Modern Chemistry.) Pp. vii+88. (Nelson: London, November 1969.) 40*s* boards; 20*s* paper.

THE book is short, comprising six chapters covering solute–solvent interaction, protonic solvents, liquid oxide solvents, oxyhalide solvents, liquid halides and fused salts. The first chapter is deservedly the longest, dealing with the energetics and mechanisms of solvation and solvent self-ionization. In this field it is refreshing to find recognized a few non-aqueous solvents, for example, acetone, which are not noted for self-ionization or participation in reactions. It is also encouraging to find solvation differentiated from ligand coordination. All the solvents discussed are adequately documented by their physical data. Each chapter ends with a short bibliography and some revision exercises.

The sections on particular solvent types are excellently furnished with explicit stochiometrical equations, which makes for smooth reading. The book is suitable as a rapid sketch of the field for a student, but some additional background explanation would improve it in this respect. Thus, for example, Lewis acids and the Lux–Flood theory are rather taken for granted. Similarly, while the electrochemical aspects of the various solvents are well recognized, apart from a reference to the Shedlovsky equation the theoretical bases of Λ_0 and K_A are left undefined. On page 44 the author identifies chemical affinity with exothermicity and it is to be hoped that he will subsequently correct this general impression even if the case in point seems an approximate justification.

S. R. C. HUGHES

MODULAR FORMS

Modular Forms and Dirichlet Series

By Andrew Ogg. (Mathematics Lecture Notes Series.) Pp. xviii+173. (W. A. Benjamin: New York and Amsterdam, 1969.) n.p.

THESE notes cover the basic properties of Hecke operators on the modular group and its principal congruence subgroups, and of Dirichlet series with Euler products and functional equations. Chapter one is an account of Hecke's work on Dirichlet series with signature (λ,k,C). Chapter two discusses Hecke operators on the full modular group, treated as correspondences on a set of lattices, completed in chapter three using the Petersson inner product. Chapter four extends the theory to congruence subgroups, including the explicit construction of Eisenstein series. Chapter five gives Weil's characterization of forms on $\Gamma(N)$ by means of functional equations for associated Dirichlet series, and chapter six gives a brief account of theta series based on quadratic forms following Hecke and Schoeneberg.

The book covers material not readily available elsewhere, because the literature is diffuse even for readers of German. Hecke's own papers do not use the Petersson inner product, and Petersson's refer remorselessly back to Hecke for basic results, as well as being too general for a first reading. The author's style is discursive, with frequent digressions and anticipations, but this is an advantage for didactic purposes. A disadvantage for the novice is his cavalier treatment of the main definition: a "modular form" is defined three times (II-2, III-5, IV-3), each relevant for its immediate context, but the reader should be told that other writers might allow poles but disallow any subgroup of $GL^+(2,\mathbb{R})$. Similarly the author's definition of "dimension" agrees with those of Klein, Hecke and Petersson, but his notation (k for $-k$) does not; and "level" is not always confined to congruence subgroups. Finally, the author's convention (I-32 *et seq.*) that $-1/\tau+1$ means $-1/(\tau+1)$ really is peculiar to himself, and he should warn the reader in advance. But these are minor issues which do not arise if the book is used as a text for a lecture course, and the author's treatment of the subject is largely both logical and readable.

It is therefore unfortunate that the presentation and appearance of the book do not do the text justice. The book was printed directly from a typescript, in the interests of rapid publication. The typing is neatly done, though inevitably not as clear as print when so many suffixes and indices are used, but there are some needless visual difficulties. The text runs on continuously, broken only by chapter headings and the underlining of definitive words, so that the main results do not stand out. It is often hard to see when the statement ends for a theorem proved in advance, or the proof for one proved in arrear. These faults, however, can largely be remedied with a pen and ruler, and do not detract seriously from a useful addition to the literature.

A. O. L. ATKIN

MATHEMATICAL LOGIC

Mathematical Logic and Hilbert's ϵ-Symbol

By A. C. Leisenring. (University Mathematical Series.) Pp. ix+142. (Macdonald (Technical and Scientific): London, October 1969.) 60*s*.

THIS book on mathematical logic is very much devoted to Hilbert's ε-symbol, a subject that normally is not given prominence in textbooks. The author has tried to make the book self-contained and hopes that it will be useful as supplementary reading in an undergraduate course. The ε-symbol has some advantages in formal set theory; only time will tell whether it should have a higher status as a topic in mathematical logic—my opinion is that its status will not change very much.

The book is well written, but the reader will need to start with some background knowledge of logic. The content of the book is sufficiently distinctive for it to be recommended as supplementary reading to any course on logic, and the book would be a useful addition to any library.

The text begins with an eight page introduction that is readable and worth reading. The first chapter introduces a formal language and studies the semantics of this language. Deductive properties of systems based on the formal language are studied in the second chapter. Some knowledge of a standard text may be helpful to put in perspective the author's stress on the ε-calculus and its advantages over the predicate calculus. In chapter three Hilbert's ε-theorems (which say, very roughly, that the ε-calculus and predicate calculus are equally powerful) and some related results are proved, and in chapter four it is shown that the ε-calculus is useful in formal set theory and in proofs of consistency. In the last chapter, a Gentzen type system that incorporates the ε-symbol is introduced and a cut elimination theorem is proved.

The book is well produced and ends with a four page bibliography and eight pages of indexes.

R. M. DICKER

PLANT ANATOMY

Anatomy of the Monocotyledons

Vol. 3: Commelinales–Zingiberales. By P. B. Tomlinson. Pp. xx + 446. (Clarendon Press: Oxford; Oxford University Press: London, February 1969.) 105*s*.

Vol. 4: Juncales. By D. F. Cutler. Pp. ix + 357. (Clarendon Press: Oxford; Oxford University Press: London, October 1969.) 100*s*.

THESE two volumes make further substantial progress in the serial publication of the *Anatomy of the Monocotyledons*. The editor, Dr Metcalf, has now retired from the Royal Botanic Gardens, Kew, but he will continue to edit the series; and both he and the authors of these volumes are to be congratulated on the excellent progress which is being made.

Volume three is in two sections. In the first, Dr Tomlinson deals with the eight families which form Engler's order, the Farinosae, including the Bromeliaceae. The second covers another series of eight families in the order Zingiberales, including the Musaceae. The account of each family begins with several pages of general anatomical description (though, regrettably, a formal description of the family is not given); this is followed by sections, of variable length, on the individual anatomical features. The literature is well covered, and there are many clear diagrams and drawings. The text is chiefly designed for reference, but it is well written and set out, so that it is comparatively easy to gain an impression of the anatomical features of a family. There are some special sections, such as that on the ecological anatomy of the Bromeliaceae, which are brilliantly done. There are short appendices on the distribution of diagnostic features in the families, which will be of use in identification, and there is also an interesting short discussion on stomatal ontogeny. Some taxonomic problems, in both orders, are discussed in the light of the new anatomical evidence available, and the weight of this evidence is assessed. The amount of original work presented is large, and the volume represents a major contribution to our knowledge of tropical monocotyledons.

Volume four differs in several ways from volume three. Dr Cutler deals with only a single order, the Juncales, with six families, in a book which is three-quarters the length of volume three; and the treatment, which is of a high standard in both text and illustrations, is accordingly much more detailed. In particular, 215 pages are devoted to the Restionaceae, a family of the southern hemisphere. This account consists of a general introduction (but again, there is no formal description), followed by an artificial key to the twenty-four genera. The anatomy of each genus is then described, the genera being arranged alphabetically. Some of the descriptions are very detailed; thus 50 pages are devoted to the genus *Restio*, of which eighty-four species have been examined anatomically by the author. This very thorough treatment is not only important for identification and morphological study; it has considerable potential value as a means of elucidating the taxonomy of the group in relation to its geographical distribution. While this aspect of the matter is not omitted in the author's account, it is not, in my view, given sufficient prominence, nor are the threads drawn together as neatly as they might be. Thus, three somewhat inconsistent statements are made (p. viii, p. 116 and p. 296) about the South African and Australian species of *Restio* and whether they should continue to be regarded as being within the compass of a single genus. This is a question of great phytogeographical interest. It is unlikely that anybody knows more about it than Cutler; and it is a pity that he has not been able to devote a few pages to a critical discussion and a decision.

Both volumes are well printed and indexed and are reasonably priced. D. H. VALENTINE

GREENFINGERS IN AMERICA

A Short History of Botany in the United States

Edited by Joseph Ewan. Pp. ix + 174. (Hafner: New York and London, 1969.) $7.50.

HOST countries to international botanical congresses in recent years have provided participants with a brief guide to their country's contribution to the development of botanical science. The proceedings of the eleventh International Botanical Congress, which was held in Seattle in August 1968, are reported in this volume. It outlines the growth of knowledge of the floral richness of the United States, and the important role of American botanists in the advance of botanical research. The type of presentation, a volume of essays by experts in their respective fields, is not ideal, but the method was obviously dictated by the short space of time available for the volume's production. Professor Joseph Ewan, one of the leading historians of biological science in the United States, has contributed two essays and edited the other contributions. His essay, "Early History", opens the door to the fascinating story of the gradual discovery of the natural wealth of America. Many of the early naturalists came from Great Britain and later in the early nineteenth century a number of British plantsmen conserved and enhanced the floral wealth of the USA. This contribution was in no way one-sided, for many of the garden plants and trees loved today in Great Britain came from America in the seventeenth and eighteenth centuries. Britain's countryside and the gardens of many famous country houses were also greatly enhanced at that period by the extensive planting of American trees.

The other essays deal largely with post-World War II advances. The individual treatment of these subjects is unavoidably uneven, but they present a useful record. The essays could not be more concise. The editor has wisely omitted references to the published work of the various botanists mentioned. This detail can, however, be obtained from consulting the items given in the list of "Recommended Reading". The "Calendar of Events", a chronological list of important American events, discoveries and publications of botanically significant works, is a unique feature which with the "Index of Persons" giving birth and death dates must have been a labour of love on the part of the editor. I have noted one error in the "Calendar"—Schweintz, L. D. *de Snyopsis fungorum Carolinae* . . . is listed as being published in 1818 whereas it should have appeared under the date 1822.

This book will prove a valuable, up to date, quick reference to the development of botanical science in general and the achievements of American botanists in particular. The editor and the publishers are to be congratulated on producing an attractive publication which should be in every botanical library. PHYLLIS I. EDWARDS

AUSTRALIAN GEOLOGY

Stratigraphy and Palaeontology

Essays in Honour of Dorothy Hill. Edited by K. S. W. Campbell. Pp. xxiii + 390. (Australian National University Press: Canberra, October 1969.) $A17.50.

THIS volume consists of twenty papers of varying length distributed into four groups: interpretative palaeontology, biostratigraphy and biogeography; descriptive palaeontology and palaeoecology; geomorphology; and sedimentation.

In the first group, Bulman demonstrates that protheeal folds originated more than once among graptolites and that *Dicellograptus* is probably polyphyletic. Wells indicates that details of the actual growth of dissepiments have not been directly observed in recent corals, but the growth patterns support the idea that it is centripetal.

Sutherland and Haugh give a detailed account of the structure and development of a discoid rugose coral, *Gymnophyllum*, from the Westphalian of Oklahoma. Birenheide adds to knowledge of a stromatophore from the Oligocene of Germany. Jell, in a study of the septal microstructure of the Phillipsastraeidae, indicates the polyphyletic nature of many of its genera and also suggests that ultimately fasciculate, cerioid, thamnasterioid and aphroid species with similar internal structure may come to be regarded as congeneric and that the corallum form is unlikely to be of suprageneric significance. I would point out that this is a state of affairs similar to that in the Graptoloidea.

The first paper in the second group is by Campbell and McKellar on the Eastern Australian Carboniferous faunas. These are of general interest because they are associated with glacial deposits in New South Wales and recent palaeomagnetic studies have provided a stimulus to the consideration of the palaeoclimatic and palaeolatitudinal distribution of these faunas. A zonal scheme based largely on brachiopods is given. It is claimed that, for Australia, the palaeomagnetic evidence summarized by Irving and the geological data here summarized are remarkably consistent. The authors, on the other hand, are critical of the data so far known from other continental areas for the same period. Jull on the Lower Carboniferous corals of Eastern Australia has important comments on the taxonomy of *Lithostrotion* and *Orionastraea*. Cretaceous faunas are treated in two papers by Day, Dettmann and Playford from the point of view of the palaeogeography and correlation especially by palynology which has received much attention and proved its worth in relatively detailed correlation. Two papers by Dickins, Gostin, Runnegar and Whitehouse summarize notable advances in various aspects of the correlation, palaeoclimatology and faunal distribution of the Permian of New South Wales and Queensland. Pursuing the same general theme Wass, in a study of Permian Polyzoa, shows that there is greater similarity between Eastern and Western Australian forms than suspected hitherto and that the distribution routes probably lay to the north rather than to the south of the continent.

The third group of papers is descriptive. Bartholomai describes a Cretaceous elopid fish and Fleming adds to the relatively meagre knowledge of uppermost Carboniferous faunas by describing that from the Neerkol Formation of Queensland. Runnegar, in a paper on Permian fossils from the southern extremity of the Sydney basin, shows that current interpretations of the palaeogeography of the basin are in need of revision, and Dear describes a new linoproductid from the Upper Permian of Queensland whose closest comparison is with forms from the Kazanian of the Taimyr Peninsula of north USSR. Strusz in a description of certain Devonian cystiphylloid corals demonstrates their close affinity with species from Europe and less so with those of North America.

In the last group of papers, Ferguson gives an account of two Cainozoic erosion surfaces, one pre-volcanic and one lateritic, in south Queensland. Driscoll provides an interesting study of animal sediment relationships of Mississipian formations in Michigan and successfully applies recently published concepts from studies by oceanographers of present day conditions. The last paper is a valuable summary by Maxwell of the structure and development of the Great Barrier Reef. The complexity of the factors involved is well indicated, and it is to be hoped that this account will help in the efforts currently being made to conserve this extraordinary and unique feature of the Earth for the research and enjoyment of future generations.

The volume is well produced and the illustrations, both line and half tone, are excellent. It gives an indication of the enormous recent advances in the knowledge of Australian palaeontology and stratigraphy. It is a worthy tribute to Professor Dorothy Hill, whose research and teaching have inspired many of these papers and whose efforts to interest authority in the wealth of material in Australia are now meeting, in some measure, the support they deserve.

J. SHIRLEY

COMPARATIVE ZOOLOGY

Principles of Comparative Anatomy of Invertebrates

By W. N. Beklemishev. Translated by J. M. Maclennan. Edited by Z. Kabata. Vol. 1: Promorphology. Pp. xxx + 490. Vol. 2: Organology. Pp. vii + 529. (Oliver and Boyd: Edinburgh, February 1970.) 200*s* the set.

IT is difficult to do justice to this intellectual *tour de force* in a short space. My first impression of the work was that it would have gladdened the heart of McBride. On further acquaintance, I still approach it with some reservations. It should be made clear at the outset that this is not a book for the beginner. Rather, it should be read by those who have been devoted to invertebrates for some time and have a considerable knowledge of invertebrate structure and systematics. To give but one example: while the fate of the rosette cells resulting from spiral cleavage is discussed, there is no explanation of how $1a^{111}$–$1d^{111}$ are derived. Great stress is laid on such details, and terms such as homoquadrant may confuse the average student. Acceptance of *Polygordius* as showing a "primitive" type of development will not appeal to all.

The book is published in two volumes separately paged but with all the references and an index at the end of the second volume. It is a translation of the third (1964) edition. In the same year, Oxford University Press published Professor R. B. Clark's *Dynamics of Metazoan Evolution*. It would be hard to find a more contrasted approach. Beklemishev's is strictly classical. Yet, when so many new books present fewer and fewer facts, fewer arguments and more conclusions, those of us who still believe that comparative morphology is of vital importance in understanding the way in which animals have evolved can but welcome the translation of this outstanding work. On the other hand, there is much with which one must disagree. And it is for this reason that the book will perhaps best be appreciated by those with some knowledge of invertebrates. Sedgwick's, and later Remane's, views on the origin of the coelom and the mesoderm are stressed. The ctenophores thus occupy a special place, and while the book does bring together so many diverse facts in a well ordered manner, it is surprising to find serious comparisons made between the tentacles of *Rhabdopleura* and of ctenophores. Hadzi's book is not mentioned; nor, for that matter, is Sharov's—though perhaps this is a blessing.

Personally, I do not like such terms as "promorphology", and "architectonics". There are also some errors of judgment on the part of the translators, though these are few and the translation for the most part is excellent. Annelid "septa", for example, are unfortunately translated as "dissepiments", while (page 256, vol. 1) septum is used to describe the thoracic collar of serpulids. The nereid peristomium is said to have three segments (page 243, vol. 1) but elsewhere (page 258, vol. 1) only two. But I have found few statements likely to cause confusion.

The bibliography is remarkably good, yet there are omissions. Some have been mentioned already. Beklemishev was clearly acquainted with Manton's work, and also that of Tiegs, yet Tiegs and Manton's important paper[1] is not mentioned. Nor, of course, when this edition appeared, was Anderson's work[2] or that of Åkesson[3] on the *Lopadorhynchus* larva known. I would like to think that less stress would have been laid on the earlier work of Kleinenberg and of Meyer and on the importance that other zoologists attached to their work at that time if the author had known of this new work. Similarly, it is a pity that Ivanov's views on the germ layers and his concept of "primary" and "secondary" segments which cannot now be accepted should occupy such important corners in Beklemishev's argument. He therefore uses terms such as "kinetoblast" and "phagocytoblast".

Yet there is much to be gained from a reading of these volumes. The comparative approach to the muscular systems, circulatory systems, reproductive organs and to the development of the colonial habit in diverse phyla is stimulating in the detail in which each comparison is made.

This is a book which every zoology department should have in its library. It is a mine of information, much of which is not readily available except in specialist texts or papers. It is well printed and produced, and the publishers are to be congratulated on making this work available in English. R. P. DALES

STUMPTAIL BEHAVIOUR

The Behavioral Repertoire of the Stumptail Macaque

A Descriptive and Comparative Study. By Mireille Bertrand. (Bibliotheca Primatologica, No. 11.) Pp. xi+273. (Karger: Basel and New York, 1969.) 122*s*; $14.65.

THIS monograph describes in detail the behavioural repertoire of *Macaca speciosa*. Most of the information was obtained from observations of captive animals—usually ones living in groups in large cages. A brief field study allowed a few comparisons to be made with the behaviour of wild animals, and in some cases comparisons are made with the behaviour of other primate species.

The first two chapters deal with the taxonomy and distribution of stumptails, and with the materials and methods used in the study. The next chapter presents quantitative data on the proportion of time spent in various occupations (for example, feeding, grooming, locomotion) by the groups of captive animals. The group structure was manipulated so that the behaviour of non-adults alone could be compared with that of non-adults in the presence of adults and vice versa. Not surprisingly there were differences, and furthermore a few observations on a wild group suggested that they differed from the captive ones.

The following seven chapters each contain detailed descriptions of different types of behaviour. It is unfortunate that the criteria for the assignment of patterns or groups of patterns between these chapters are not consistent. For instance, play is assigned as follows: locomotory play is with locomotion because some of the same motor patterns are involved (a descriptive criterion); rough-and-tumble play is with agonistic and friendly behaviour because of its comparability with agonistic behaviour and because of a similarity in function in establishing dominance (descriptive and functional criteria); investigatory play is with watchful and alarm behaviour because they are elicited by the same kinds of environmental stimuli (a causal criterion). The behavioural category "play" is undoubtedly too broad to be specially useful, particularly when function is being considered, but the subdivision of this or any other such category on variable criteria is no more than a hindrance.

The observations are, however, of high quality, and the details of the postures, facial expressions and vocalizations, and of the contexts in which they occur, provide a solid basis for comparison with other species. Furthermore, anybody who has the opportunity to study the species in the wild will be much helped by the descriptions in the book. The descriptions are well supported by good photographs, including sound spectrographs, and line drawings. There is a good bibliography but, unfortunately, no index. Y. SPENCER-BOOTH

Obituaries

Earl Russell

EARL RUSSELL, OM, FRS, died on February 3, 1970, at the age of 97. As a philosopher in the widest and oldest sense of the word, he had the rare ability to communicate lucidly with layman and professional philosopher alike, and to extend the range of his interests consistently from symbolic logic to social involvement. His intellectual scope included politics, the history of philosophy, mathematics and, not least, science.

Bertrand Russell's philosophy of science was very much a product of his wider philosophical and logical interests. After his pre-1900 abandonment of idealism, Russell became a logical realist and a pluralist. His analysis of science was dominated by two powerful maxims. The first was a determination to pursue a robustly realistic "common sense" attitude to those objects, both concrete and abstract, with which science deals. The "real" things in the world were not inextricably mental—the pervading orthodox view—but independent, individual things whose discovery and description required an analysis of human belief in order to find their correct form. These forms were to be expressed in simple or "atomic" propositions.

Pursuing this analysis in *The Principles of Mathematics* (1903) Russell was to find an overabundance of "real" things: "A man, a moment, a number, a class, a relation, a chimaera or anything else that can be mentioned"—such an excess constituted a challenge to an orderly and disciplined mind. Nevertheless, his pursuit of this analysis placed and kept him firmly in the British empiricist tradition.

In the writing of his *magnum opus*, the celebrated *Principia Mathematica*, Russell developed the techniques of "logical construction" of one entity from another which were to support his second maxim: "Whenever possible, substitute constructions out of known entities for inferences to unknown entities". Numbers become classes of classes of objects and later, in *The Analysis of Matter* (1927), objects became classes of events, which were constructed from classes of sense impressions.

Although a good deal of Russell's analysis of the content and validity of our knowledge of the world is conducted at an abstract level (as, for example, in *Our Knowledge of the External World*, 1914) he did not hesitate to plunge where necessary into a detailed analysis of current scientific theories. An example of this was *The Analysis of Matter*, in which he discussed the theory of quanta, special relativity, geodesics, invariants, differential equations, the theory of measurement and of space and time.

Perhaps his most direct influence on the philosophy of science has been in these applications of logical construction and other symbolic techniques which first appeared in the *Principia*. Their effect on modern logic (and mathematics) has been incalculable. The success of this analytic approach moved many other philosophers, including the Vienna Circle group of logical positivists, to attempt similar projects in the physical sciences.

Much later in his career (*Human Knowledge: Its Scope and Limits*, 1948) Russell turned again to a sustained attack on the problems specifically related to science and provided a more modern analysis of a number of basic scientific concepts. In this work he presented his analysis of two problems that have been prominent in the philosophy of science: namely, the difficulty of providing a formally correct and materially adequate definition of the nature of probability statements, and the provision of a theory of non-deductive inferences as they are used in the sciences. In 1950 Russell was a founder member of the British Society for the Philosophy of Science.

Characteristically, Russell had no hesitation in attempting the difficult task of bridging the ever widening gap between philosophy and science. In writing *The ABC of Quanta* (1923) and *The ABC of Relativity* (1924) he presented, perhaps somewhat idiosyncratically, the fruits of modern science predigested for philosophers, and demonstrated the benefits of analytic philosophy in a manner palatable to scientists. A Herculean task!

Beyond his philosophy of science, Russell was an indefatigable popularizer of science and an exponent of the application of scientific method to the solving of social, political, moral and philosophical problems. *Our Knowledge of the External World* was subtitled "As a field for Scientific Method in Philosophy". He was undoubtedly among the pioneers who called for social responsibility on the part of scientists and he acted accordingly, in repeatedly analysing the impact of science and technology on society.

Perhaps some insight into the source of Russell's continuing influence is found in the concluding paragraph of *Human Knowledge*. "In this sense, it must be admitted, empiricism as a theory of knowledge has proved inadequate, though less so than any other previous theory of knowledge. Indeed, such inadequacies as we have seemed to find in empiricism have been discovered by strict adherence to a doctrine by which empiricist philosophy has been inspired: that all human knowledge is uncertain, inexact and partial. To this doctrine we have not found any limitation whatever."

Can a Scientific Article be Libellous?

SIR,—In a case before the Court of Appeal, reported in *The Times* (February 13, 1970), a dental surgeon was given leave to take libel action against the British Medical Association and others. The Court held that "a scientific paper in the *British Medical Journal* which was critical of a technique for dental anaesthesia introduced, used and recommended [previously in the same journal] by a named dental surgeon was held by a majority of the Court to be capable of bearing a meaning defamatory of the surgeon in the way of his profession and that it should not therefore be struck out *in limine* as disclosing no reasonable cause of action". While the judges avoided implications as to the likely outcome of such action in court, they maintained that a suit for libel was justified. As suggested in the dissenting judgment by the Master of the Rolls, Lord Denning, the ramifications of this decision on the scientific world could be serious.

The central issue in the majority judgment was expressed by Lord Pearson, who was reported as saying that "the author's name, practice and reputation have been and were closely associated with the technique in question". Therefore, an attack on the technique held forth the possibility of being an attack on the author and must be entered to jury-decision. In suits claiming libel, the defendant must prove to a jury's satisfaction that his actions did not constitute a personal, subjective defamation of the plaintiff. However, the cost in time and funds to prepare a case to the satisfaction of a lay-jury could be prohibitive to many research efforts and personally ruinous to the defendant.

The Master of the Rolls was reported as expressing that "it would be a sorry day if scientists were to be deterred from publishing their findings for fear of libel actions. So long as they refrained from personal attacks, they should be free to criticize the systems and techniques of others. It was in the interest of truth itself. Were it otherwise, no scientific journal would be safe". On the basis of the judgment in this case, allowing the libel action to proceed, there is clearly cause for concern for all of us. Within the scientific community one accepts that criticism is given and taken. While reputations may be enhanced or damaged in this manner, it rarely becomes a legal issue. However, individual criticism of any research involving commercial interests would appear now to be open to the risk of expensive libel action.

Should Slides be Seen Blind?

SIR,—The suggestion is in the wind that, in the safety evaluation of drugs and potential food additives, histopathological material derived from studies on animals should be examined "blind"; that is to say, by a pathologist who is not told which material is derived from treated animals and which from untreated controls. If this suggestion is being seriously put forward, and if it applies to the first time that slides are to be examined, then we believe it to be ill-advised.

The pathologist's appraisal of toxicity should begin with a consideration of the overall design of the experiment and of details of mortality and morbidity in animals subjected to each form of treatment. Next he should acquaint himself with the clinical history of each animal. Central to his appraisal will be observations made by the naked eye at necropsy. Subsequent microscopic examination of material taken for histopathology may or may not add to the information already gained; but it is more likely to do so if detailed clinical and post mortem reports are available to the pathologist at the time he examines the slides. In any case, unless he has these reports before him, he cannot be sure that the microtome knife has found all the lesions seen macroscopically, and he may be in doubt as to the exact location and size of lesions. This description is nothing more than a statement of the general principles of sound pathological practice as they apply to the special problems associated with the safety evaluation of drugs and other agents.

Many variables face the pathologist as he examines histological material from toxicity studies. It would be impracticable for him to consider all of them. Awareness of the nature of the experiment, the clinical and post mortem findings, and other pharmacological or toxicological information must inevitably direct his attention to relevant features which might otherwise be overlooked.

Once a preliminary survey of the slides from a safety-evaluation experiment has been made, there may be a case for the slides from selected tissues to be re-examined to confirm the presence of a qualitative change in response to treatment, or to measure an apparent quantitative difference between material from treated and control animals. This may be the point at which it would be prudent to ask the same, or a second, pathologist to examine slides "blind". Perhaps the suggestion that is in the wind concerns only such selective re-examination of material. But if primary "blind" examination is proposed, it might as well be done by a blind pathologist !

Understanding Media

Sir,—On February 15, 1969, *Nature* published a communication from Drs R. G. Edwards, B. D. Bavister and P. C. Steptoe entitled "Early Stages of Fertilization *in vitro* of Human Oocytes matured *in vitro*". To a biologist, the results seemed to be in the nature of a sound record of work in progress, more likely than not to be consistent with a true fertilization *in vitro*, and further communications were awaited with great interest. But there was at that time no evidence of the critical final stages of the fertilization process, and no development to the stage of an embryo. The results could not certainly be distinguished from those to be expected from abortive parthenogenesis, a phenomenon that bedevilled much earlier work on animals before fertilization *in vitro* was conclusively demonstrated in the rabbit by M. C. Chang and others. There was incontrovertible evidence of gross maldistribution of chromosomes in many eggs. All this was made explicit or given due reference in the paper itself.

Shortly after, if my sense of public opinion is correct, large numbers of people came to believe in some or all of the following propositions: (1) that an absolute, unequivocal proof of fertilization of the human egg *in vitro* was available; (2) that this was the first experiment on fertilization *in vitro* in man; (3) that human foetuses had for the first time been cultured *in vitro*; (4) that "life" had been "created".

Since the authors had claimed none of these things, and since all the propositions seemed at that time false, or, at best, arguable, it seems—unless my understanding of public opinion is at fault—that certain misconceptions had spread throughout the world on a large scale. Some still appear to be current. Embarrassment must certainly have been caused to the authors as well as to all others who share with them a regard for the good name of reproductive biology.

The public must necessarily derive its information on technical matters largely from the popular media of mass-communication. It might be opportune for formal enquiry to be instituted into the extent to which these media do actually succeed in giving the public a correct version of scientific material. It would be easy to blame the public itself for its misunderstandings—but perhaps it is the lines of communication that are at fault.

Yours faithfully,

R. A. Beatty

Capacity for Misunderstanding

Sir,—An important question of terminology arises in the teaching of thermodynamics. In this subject the word "heat" means energy transmitted because of a temperature difference. It very often happens that this is confused with internal energy, as a result of which serious misunderstanding arises. A recent test showed that not one of 148 university entrants in science and engineering knew the scientific meaning of heat. Consequently the first law of thermodynamics and even such an elementary concept as an adiabatic process must be meaningless to them. A contributory factor in this widespread misunderstanding may well be the use of the misleading term "heat capacity". The word capacity conveys the idea of containment, hence this term falsely suggests the containment of heat in matter. Unfortunately the equally misleading term "specific heat capacity" is coming into use.

I suggest that there would be a great educational advantage in discontinuing the use of the word "capacity" in this connexion. It would be better to use some such word as "acceptance". The "heat acceptance" of a body would mean the heat added divided by the consequent temperature rise. Heat is usually partly converted into internal energy in the body and partly into some other form of energy by means of external work. The word acceptance avoids the false implication that heat as such is contained in the body.

Yours faithfully,

J. W. Warren

Department of Physics,

Appointments

V. A. Kotel'nikov, Institute of Radio Engineering and Electronics, Moscow, has been elected to the position of vice-president of the **Academy of Sciences of the USSR.**

Dr Mahlon B. Hoagland, Dartmouth Medical School, has been appointed director of the **Worcester Foundation for Experimental Biology.**

The Secretary of State for Education and Science, **Mr Edward Short,** has appointed four new members of the **Council for Scientific Policy:** Professor G. S. Brindley, London Institute of Psychiatry; Professor A. H. Bunting, University of Reading ; Dr H. Morrogh, British Cast Iron Research Association ; Dr R. G. West, University of Cambridge.

Announcements

The Grand Prix Technique de la Ville de Paris has been awarded to **Professor Max Serruys.**

Dr Richard D. Deslattes has received an **Arthur S. Flemming award,** for his direction of research which led to the successful design, construction and demonstration of the first device combining an X-ray and optical interferometer.

The **International Commission on Radiation Units and Measurements** invites nominations for the award of the **Gray medal.** The medal will be awarded for outstanding contributions in a field of interest to the Commission, and will probably be presented during the ICRU meeting in 1971. Further details can be obtained from W. R. Ney, ICRU, 4201 Connecticut Avenue NW, Washington, DC 20008.

Between six and nine fellowships in microbiology, each lasting nine months, will be sponsored jointly by **Unesco** and the **International Cell Research Organization** to enable young scientists from developing countries to be trained in research laboratories abroad. Further information can be obtained from Unesco, Place de Fontenoy, 75 Paris 7.

ERRATUM. In the article "Effect of β-Adrenergic Blockade and Alcohol on Simulated Car Driving" by V. Goldman, B. Comerford, D. Hughes and G. Nyberg (*Nature*, **224**, 1175; 1969), the measurements of alprenolol levels in plasma in Table 2 should be in nanograms (ng) rather than micrograms (μg).

Sabbatical Itinerants

In the hope of providing some practical assistance in the good cause of mobility between laboratories, *Nature* advertises the needs for housing of families about to take up periods of sabbatical leave. To begin with, no charge will be made for advertisements like this. It is hoped that a period of experiment will show what form these advertisements could most usefully take and whether they are effective.

Wanted: 4-bedroomed accommodation for English university lecturer and family in Boston, Massachusetts area (Natick or Framingham preferred), from April 1 to December 31, 1970. Please contact Dr F. Jones, Department of Colour Chemistry and Dyeing, The University, Leeds LS2 9JT (telephone Leeds 31751, extension 6125).

Wanted: Furnished house or apartment (2 bedrooms will do) for American professor, wife and two school-age daughters in London (or convenient transport to Imperial College) from late July to December 31, 1970. Will exchange for 3-bedroom furnished house with garden within walking distance of University of California, Berkeley, available July 1 to December 31, 1970. Please contact Dr J. G. Hancock, 2225 Ward Street, Berkeley, California 94705, USA.

Wanted: 1–2 bedroomed, furnished house or flat, preferably in the London WC1 area, for visiting fellow and his wife, from September 1970 for 12 months or more. Please contact Dr G. Gregoriadis, Department of Medicine, Albert Einstein College of Medicine, 1300 Morris Park Avenue, Bronx, NY 10461, USA.

Vacant: From September 1970 to September 1971, detached, furnished house, 3 bedrooms, central heating, garage, gardens. Quiet location in Congleton, Cheshire, close to Jodrell Bank telescope; also good access to Manchester and Keele Universities. Please contact Dr T. J. Franklin, 23 Birch Road, Congleton, Cheshire (telephone Congleton 3796).

Vacant: From July 6 to September 26, 1970, 3-bedroom furnished house in Aberdeen. Central heating; adjacent to University. Please contact Professor P. C. Sylvester-Bradley, Department of Geology, the University, Leicester.

British Diary

Monday, March 16

Measuring Man's Needs (5.30 p.m.) Dr A. J. O'Hara-May, British Society for the History of Science, in the Lecture Theatre of the Science Museum, Exhibition Road, London SW7.

Sonar (5.30 p.m.) Mr T. N. Reynolds, Institution of Electrical Engineers, at Savoy Place, London WC2.

The Choice of Industrial Drives up to 100 hp (5.30 p.m. discussion) Institution of Electrical Engineers, at Savoy Place, London WC2.

The Parliamentary and Scientific Committee (5.30 p.m.) Mr Roger Gresham Cooke, MP, Royal Institution, Library Circle, at 21 Albemarle Street, London W1.

Tuesday, March 17

Aspects of Fertilizer Usage (10.30 a.m.) Society of Chemical Industry, Agriculture Group; and the Fertilizer Society, at 14 Belgrave Square, London SW1.

Deformation and Fracture of Soft Materials (3): Strength of Adhesive Bonds (4.30 p.m.) Professor A. N. Gent, University of London, at Queen Mary College, Mile End Road, London E1.

Differential Thermal Analysis (2.30 p.m.) Society for Analytical Chemistry, East Anglia Section, at Spillers Ltd, Technological Research Station, Station Road, Cambridge.

Electrical Methods of Machining, Forming and Coating (three-day conference) Institution of Electrical Engineers, at Savoy Place, London WC2.

Management and Economics in the Electronics Industry (four-day international symposium) Institution of Electronic and Radio Engineers; and the Institution of Electrical Engineers, at the University of Edinburgh.

Noise Reduction in Manipulative Machinery (6 p.m. discussion) Institution of Mechanical Engineers, at 1 Birdcage Walk, London SW1.

Rubber and Plastics for Use in Hovercraft (7.30 p.m.) Institution of the Rubber Industry, at Retford.

The Nature and Hazards of Nuclear Fallout (7.30 p.m.) Dr R. E. Ellis, British Society for Social Responsibility in Science, at the Blackhorse, Rathbone Place, London W1.

UNIDO and Its Work in the Petrochemical and Plastics Field in Developing Countries (6 p.m.) Mr H. May, Society of Chemical Industry, at 14 Belgrave Square, London SW1.

Wednesday, March 18

Chromosomal Abnormalities in Blood Diseases (2 p.m.) Dr Sylvia D, Lawler, University of London, at the Royal Postgraduate Medical School, Du Cane Road, London W12.

Computer Typesetting (7 p.m.) Mr R. Chapman, Institution of Electronic and Radio Engineers; and the British Computer Society, at the University of Bristol.

Electronic Engineering in the Solution ot Harbour Approach Problems for Large Ships (6 p.m.) Mr T. W. Welch, Institution of Electronic and Radio Engineers, at 9 Bedford Square, London WC1.

Filtration (9.30 a.m. symposium) Institution of Chemical Engineers, at Victoria Halls, Bloomsbury Square, London WC1.

Foams (2 p.m. symposium) Plastics Institute, at the Great Western Royal Hotel, Paddington.

Gas Turbines—Combustion Chambers—One Large or Many Small? (6 p.m. discussion) Institution of Mechanical Engineers, at 1 Birdcage Walk, London SW1.

Is It Strong Enough? (1.10 p.m.) Professor M. L. Meyer, City University, at the Graduate Business Centre, Gresham College, Basinghall Street, London EC2.

Manoeuvre Demand Control for Aircraft (5 p.m.) Mr G. T. Shanks, Institute of Navigation, at the Royal Institution of Naval Architects, 10 Upper Belgrave Street, London SW1.

Modern Dairy Science (2.30 p.m.) Mr E. L. Crossley, Royal Society of Arts, at John Adam Street, London WC2. (E. F. Armstrong Memorial Lecture.)

Recent Advances in Diagnostic Agents and Techniques (10 a.m.) Nuclear Medicine Committee, Middlesex Hospital Medical School, at the British Institute of Radiology, 32 Welbeck Street, London W1.

Thursday, March 19

Automation in Production, Sampling and Testing of Silicate Materials (9.30 a.m.) Society of Chemical Industry, Road and Building Materials Group, at Victoria Halls, Bloomsbury Square, London WC1.

Clay and Colloid Particles: Size, Shape and Dispersion (two-day spring meeting) Mineralogical Society; jointly with the Basic Science Section of the British Ceramic Society, at the Department of Agricultural Science, Downing Street, Cambridge.

Electronic Aids to Night Vision (4.30 p.m.) Mr P. Schagen, Royal Society, at 6 Carlton House Terrace, London SW1.

High Energy Ignition on Jet Aeroengines—a Survey of Current Techniques and Future Trends (7 p.m.) Mr B. R. Clifford, Institution of Electronic and Radio Engineers, at Medway College of Technology, Chatham, Kent.

Inducers and Supercavitating Pumps (6 p.m. discussion) Institution of Mechanical Engineers, at 1 Birdcage Walk, London SW1.

Influence of Stricture on the Base Metal Deposits of Southwest Sardinia, Italy, Mr J. C. McM. Moore; **Genesis of the Forari Manganese Deposit, New Hebrides,** Mr A. J. Warden (5 p.m.) Institution of Mining and Metalurgy, at the Geological Society, Burlington House, Piccadillly, London W1.

Laser Applications in Electronics (7.30 p.m.) Professor W. A. Gambling, Institution of Electronic and Radio Engineers, in the J. J. Thomson Physical Laboratory, University of Reading.

Neutron Therapy (5.45 p.m. discussion); **Tissue Heterogeneity and Treatment Planning** (7.15 p.m.) Dr A. H. Laing, Mr G. Innes and Dr T. E. Burlin, British Institute of Radiology, at 32 Welbeck Street, London W1.

Paint User Test Methods (half-day conversation) Oil and Colour Chemists' Association, in the New Engineering Block, University College, London, Gower Street, London WC1.

The Code of Practice for Cathodic Protection (5.30 p.m. discussion) Institution of Electrical Engineers, at Savoy Place, London WC2.

Friday, March 20

Automatic Methods in Analysis (6.30 p.m. discussion) Society for Analytical Chemistry, Western Section, at the George Hotel, Chepstow.

Cosmetics—Odour and Colour (6.30 p.m.) Mr J. P. Slater, Oil and Colour Chemists' Association, at the Chamber of Commerce House, 75 Harbourne Road, Birmingham 15.

European Conservation—Action Now (1.15 p.m.) Mr R. J. S. Hookway, Institute of Rural Life at Home and Overseas, at Friends International Centre, Courtauld House, Byng Place, London WC1.

Microwave Filters (5.30 p.m. discussion) Institution of Electrical Engineers, at Savoy Place, London WC2.

Proteolytic Enzymes (6.30 p.m.) Dr R. G. W. Spickett, Society of Chemical Industry, at 14 Belgrave Square, London SW1.

Technological Forecasting and Corporate Long-range Planning (5.30 p.m.) Dr B. C. Lindley, Institution of Electrical Engineers, at Savoy Place, London WC2.

The Mechanism of Visual Receptors (9.45 a.m. all-day meeting) British Photobiology Society, at the Institute of Ophthalmology, Judd Street, London WC1.

Saturday, March 21

Village Craftsmen of Buganda (3.30 p.m.) Mr Bruce Kent, Inner London Education Authority, at the Horniman Museum, London Road, Forest Hill, London SE23.

Monday, March 23

Electrical Aspects of Spacecraft (7.30 p.m.) Mr H. J. H. Sketch, Institution of Electrical Engineers, at the J. J. Thomson Laboratory, University of Reading, Whiteknights Park, Reading.

Integrated Management Systems in Manufacture (5.30 p.m.) Mr F. N. Stephenson, Institution of Electrical Engineers, jointly with the Institute of Measurement and Control and the I.Mech.E., at Savoy Place, London WC2.

Memorial Service for Lord Jackson of Burnley, FRS (12 noon) at Holy Trinity Church, Prince Consort Road, London SW7.

Newer Polymers (10 a.m. symposium) Society of Chemical Industry, Plastics and Polymer Group, in Physics Lecture Theatre 1, Imperial College, London SW7.

Overhead-line Oscillations and the Effect of Aerodynamic Dampers (5.30 p.m.) Mr J. C. R. Hunt and Mr D. J. W. Richards, Institution of Electrical Engineers, at Savoy Place, London WC2.

Structural Dynamics (three-day symposium) Loughborough University of Technology, in association with the British Acoustical Society; the Institution of Civil Engineers; the Institution of Mechanical Engineers; and the Royal Aeronautical Society, at the University.

The Biochemistry of Steroid Hormone Action; Cerebral Enzymes and Isoenzymes; Membrane-bound Enzymes; Mitochondria and Calcium Transport, Professor A. L. Lehninger (Fifth Jubilee Lecture) (two-day meeting) Biochemical Society, at University College, London, Gower Street, London WC1.

The Dielectric Properties of Heterogeneous Systems including Biological Materials (three-day meeting) Dielectrics Discussion Group, at the University College of Wales, Aberystwyth.

The Shape of Things: General Conceptions of the Nature of Things (7.45 p.m.) Mr Ian Ross, H. G. Wells Society, in the Common Room of the Electrical Engineering Department, Imperial College, Exhibition Road, London SW7.

APPOINTMENTS VACANT

UNIVERSITY OF EDINBURGH

DEPARTMENT OF BOTANY

Applications are invited for posts of LECTURER and UNIVERSITY DEMONSTRATOR in the above Department.

LECTURER

Preference will be given to applicants having qualifications in Botany and Biochemistry. The duties involve teaching plant biochemistry and plant physiology to elementary and advanced students. The successful candidate will also be expected to engage in research. A number of workers in the Department are developing an investigation into certain aspects of the relation between protein synthesis and growth. A candidate already working in this general field would be of particular interest.

Salary Scale: £1,240 to £2,850 per annum, together with F.S.S.U. benefits.

DEMONSTRATOR

The successful candidate will be expected to assist with the teaching of advanced and elementary students, and to engage in research.

Salary Scale: £1,060 to £1,445 per annum, together with F.S.S.U. benefits.

Applications, by letter (three copies), giving full details of qualifications and experience, together with the names of two referees, should be sent to the Secretary to the University, Old College, South Bridge, Edinburgh, EH8 9YL, not later than March 20, 1970. Please quote reference 1018 Lecturer and 1019 Demonstrator.

(1006)

UNIVERSITY OF DURHAM

DEPARTMENT OF CHEMISTRY

POST-DOCTORAL RESEARCH ASSISTANTSHIP
in Organo-transition Metal Chemistry

Applications are invited for a Post-doctoral Research Assistantship tenable for a period of up to two years in collaboration with Dr. M. Kilner. The investigation will be concerned with an infrared spectral study of the interaction of small molecules, particularly CO, H_2, N_2, $RCH{=}CH_2$ and O_2, with a series of organo-transition metal complexes at high pressures and temperatures using a specially constructed high pressure cell.

Salary in the range £1,200 by £85 to £1,455 per annum with F.S.S.U. Starting date negotiable.

Applications (three copies, overseas one copy), including a curriculum vitae and the names of three referees, should be sent by April 20, 1970, to the Registrar and Secretary, Old Shire Hall, Durham, from whom further particulars may be obtained.

(1034)

MICROSCOPE SALES

WILD HEERBRUGG (U.K.) LIMITED require a **Technical Field Representative** for their Microscope Division promoting and selling Swiss precision instruments. The territory to be covered will be in the North of England.

Applicants should either be Representatives experienced in microscope selling or men with wide experience in the application of microscopes. The post is an important one in an expanding Company and a high salary will be paid to the successful applicant.

Applicants should write to:

The Managing Director,
Wild Heerbrugg (U.K.) Limited,
49-51 Church Street,
MAIDSTONE, Kent.

(1040)

IRELAND

BIOCHEMIST

required for
CORK HEALTH AUTHORITY
Salary: £2,385–£2,900.

Essential: M.Sc. in biochemistry or physiological chemistry, or equivalent, and five years' experience of biochemistry or chemical pathology. If a suitable candidate is appointed, University College, Cork, proposes to establish in the College a Part-time Lectureship in the subject. The salary envisaged for such a post is of the order of £1,000 per annum. Post-entry training in Clinical Biochemistry, if necessary, with full pay.

Application forms and further particulars from Secretary, Local Appointments Commision, 45 Upper O'Connell Street, Dublin 1.

Latest date for receiving completed application forms:
April 15, 1970

(1043)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BOTANY

CARBOHYDRATE METABOLISM IN FUNGI

Applications are invited from those with the relevant research experience in biochemistry, plant physiology or microbiology to take a major part in a programme of research in the Department of Botany into carbohydrate biochemistry of fungi with particular emphasis on the metabolism of sugar alcohols. The appointment commences on October 1, of this year and is for three years. Initial salary £1,265 per annum.

Applications, stating age, academic qualifications and experience, together with the names of two referees, should be received not later than May 2, 1970, by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Please quote Ref.: RV/5753/N.

(1064)

UNIVERSITY OF STRATHCLYDE

Department of Biology

LECTURESHIP

Applications are invited from suitably qualified candidates for the above post. Candidates should have a Higher Degree and/or research experience in Parasitology.

Salary scale: Lecturer, £1,240 to £2,850 per annum with F.S.S.U.

Application forms and further particulars (quoting 16/70), may be obtained from the Registrar, University of Strathclyde, George Street, Glasgow, C.1, with whom applications should be lodged not later than March 31, 1970.

(1077)

Ministry of Overseas Development

AGRICULTURAL ECONOMIST

(graded Principal Scientific Officer)

£2674–£3671

This post is based in the Land Resources Division of the Directorate of Overseas Surveys, at Tolworth, Surrey, but could involve some service overseas.

The division undertakes integrated land resource appraisals at reconnaissance semi-detailed or detailed level, advises on planning for the development and use of these resources, and undertakes or advises on feasibility studies, under technical assistance arrangements for Overseas Governments (mainly tropical countries within the Commonwealth).

The successful candidate will be concerned with appraisal of the economic aspects of project assessment and planning, and of feasibility studies for agricultural and forestry developments (including those involving irrigation); and with the collection and processing of agro-economic data in land resource surveys.

Candidates (men only) should normally have a first or second class honours degree in Agricultural Economics, or in Agriculture with postgraduate qualification in Agricultural Economics. Experience in tropical agriculture and related development and feasibility studies, and a knowledge of modern statistical and computer techniques are important. Preference will normally be given to those between 30 and 50.

Starting salary may be above minimum of the quoted scale. There is a non-contributory pension scheme, and there are prospects of promotion to Senior Principal Scientific Officer (£4,045–£4,620) and above.

For full details and an application form, write to Civil Service Commission, 23 Savile Row, London WIX 2AA, or telephone 01–734 6010 ext. 229 (after 5.30 p.m. 01–734 6464 "Ansafone" service), quoting *S/7426/70*. Closing date 9 April 1970.

(1028)

UNIVERSITY OF LONDON

READERSHIP IN SOCIAL STATISTICS AT LONDON SCHOOL OF ECONOMICS

The Senate invite applications for the Readership in Social Statistics tenable at the London School of Economics and Political Science (salary scale £2,770 to £3,670 plus £80 London Allowance).

Applications (ten copies), must be received not later than May 1, 1970, by the Academic Registrar, University of London, Senate House, W.C.1, from whom further particulars may be obtained. (1091)

UNIVERSITY OF GLASGOW

LECTURESHIP IN STATISTICS

Applications are invited for a Lectureship in Statistics. Initial salary placement within the £1,240 to £1,470 per annum range of the Lecturers' scale. F.S.S.U.

Applications (eight copies), should be lodged not later than April 4, 1970, with the undersigned from whom further particulars may be obtained. In reply please quote Ref. No. 3005-M.

ROBT. T. HUTCHESON,
Secretary of the University Court.

(1063)

UNIVERSITY OF NEWCASTLE UPON TYNE

THE MEDICAL SCHOOL

DEPARTMENT OF DERMATOLOGY

Applications are invited from suitably qualified University graduates for appointment as Junior Research Associate for research into the aetiology and treatment of acne. The appointment will be for one year in the first instance but will be renewable up to a maximum of three years in all. A suitably qualified candidate would be encouraged to read for a higher degree. The successful candidate will be paid allowances equated to those paid in the case of M.R.C. or S.R.C. Studentships.

Applications should be sent to Professor S. Shuster, The Deparament of Dermatology, The Royal Victoria Infirmiry, Newcastle upon Tyne, NE1 4LP, as soon as possible. (1062)

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

(UNIVERSITY OF READING)

BACTERIOLOGY DEPARTMENT

Microbiologist required to study the metabolism of lactic acid bacteria in pure culture and in association with other bacteria isolated from cheese. A basic study of the production of those metabolic end-products, which are related to cheese flavour, is involved. Facilities for gas-liquid chromatography and mass spectrometry are available and there are opportunities for obtaining a higher degree. Appointment will be in the grade of Scientific Officer (£1,071 to £1,827) or Senior Scientific Officer (£2,021 to £2,491) according to age and experience. F.S.S.U.

Applications, on forms obtainable from the Secretary, N.I.R.D., Shinfield, Reading, RG2 9 AT, are invited from honours graduates. Quote ref. 70/8. (1041)

UNIVERSITY OF BRISTOL

DEPARTMENT OF AGRICULTURE AND HORTICULTURE

LONG ASHTON RESEARCH STATION

FOOD CHEMIST/ BIOCHEMIST

Applications are invited for the appointment of a SCIENTIFIC OFFICER in the Domestic Food Preservation Section to undertake biochemical research on quality changes in preserved foods, with particular reference to textural changes.

The successful applicant will be required to commence on September 1, 1970, and should hold a good honours degree in Food Science, preferably having postgraduate research experience. An Honours graduate could expect to have opportunities of working towards a higher degree.

Appointment will be in the Scientific Officer grade (£1,071 to £1,827 per annum). Starting salary dependent upon age, date of degree award and postgraduate experience. Membership of the Federated Superannuation System for Universities will be compulsory.

Applications (one copy), together with the names and addresses of three referees, should be forwarded to the Registrar, University of Bristol, Senate House, Bristol BS8 1TH, by April 6, 1970, from whom further particulars of the post are available (please quote reference E.B.). (1032)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF METALLURGY

Applications are invited for the posts of

LECTURER in physical metallurgy. For one post the candidate should have a special interest in the physical metallurgy of steel; for the other post a candidate having special interest in any branch of physical metallurgy would be considered. It is hoped to make appointments from younger candidates who will have recently obtained higher degrees in the fields of research outlined. Informal inquiries should be addressed to Professor Nutting, Department of Metallurgy, Houldsworth School of Applied Science.
Reference No. 36/2/D.

SALARY SCALE: £1,240 to £2,850 (efficiency bar £2,045).

Applications (three copies), stating age, qualifications and experience and naming three referees, should reach the **Registrar, The University, Leeds LS2 9JT** (from whom further particulars may be obtained), not later than April 6, 1970. *Please quote reference number* (1047)

UNIVERSITY OF SURREY

DEPARTMENT OF MATHEMATICS

Applications are invited for the post of LECTURER IN PURE MATHEMATICS. Salary will be on the scale £1,585 to £2,045 (bar) to £2,850 per annum, with F.S.S.U. benefits.

Applications, together with the names and addresses of two referees, should be submitted by March 23, 1970, to the Academic Registrar (LFG), University of Surrey, Guildford, Surrey, from whom further particulars may be obtained.

(1035)

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF BOTANY

Applications are invited for the post of **LECTURER or ASSISTANT LECTURER** in the Department of Botany. Candidates should have an interest in Taxonomy and will be expected to assist in organising the Botanic Garden and to take part in elementary teaching. Salary scales: Lecturer, £1,585 to £2,850 with a merit bar at £2,045; Assistant Lecturer, £1,240 to £1,585. The initial salary will depend on qualifications and experience.

Further particulars may be obtained from the Deputy Secretary, The University, Southampton, SO9 5NH, to whom applications (seven copies from United Kingdom applicants) should be sent as soon as possible, quoting ref.: Na. (938)

GHANA CIVIL SERVICE

Applications are invited for the following positions in the Geological Survey Department:

SENIOR CHEMIST

Duties: To take responsibility of and supervise work in chemical laboratory; training chemical technicians and other junior personnel.

Qualifications: Postgraduate degree in chemistry with at least six years experience.

Salary: N¢4,788 by N¢126 to N¢5,544 per annum.

SENIOR PETROLOGIST

Duties: To take charge of Petrological laboratories, research into relationships of Ghana rocks and non-economic minerals.

Qualifications: A first- or upper second-class Honours degree in Geology and a postgraduate degree in Petrology with four years postgraduate experience.

Salary: As for Senior Chemist.

Supplementation of salary is payable to eligible British subjects designated by Ministry of Overseas Development for the purpose.

Appointments on contract for three tours each of 15 months. Tax free gratuity at rate of 10 per cent of salary at end of each tour of duty. Also tax free resettlement gratuity of 20 per cent of aggregate salary on satisfactory completion of contract. Free passages for officer, wife and up to three children under 18 years. An education allowance for children when not resident in Ghana and attending full-time school of £100 a child for up to three children under 18 years. Generous leave on full pay. Income Tax at low local rates.

Application forms may be obtained from: The Director of Recruitment (Overseas), Ghana High Commission, 38 Queen's Gate, London, S.W.7. (1066)

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF ANATOMY

Applications are invited from registered Medical or Science graduates, male or female, for the post of Lecturer in Anatomy and Histology. The appointment carries responsibility for teaching preclinical medical students at ordinary and honours levels. Previous teaching experience is an advantage. The appointee must engage in research work and candidates with strong investigative inclinations will be favourably considered. Duties to commence October 1, 1970. Salary will be within the scale £1,240 by £115 to £2,850. Permanent appointment of medical graduates at not less than £1,585.

Applications (two copies), together with the names of three referees, should be received by the Registrar, University College, Cardiff, from whom further particulars may be obtained not later than April 11, 1970. Quote ADV/414/N. (1065)

MINISTRY OF AGRICULTURE, FISHERIES AND FOOD

Chief Scientific Adviser (FOOD)

up to £6500

The prime accountability of this post is to advise the Minister and the Ministry generally on all questions relating to scientific and technological aspects of food and the food industry. Specifically duties will include (a) liaison with organisations conducting research and the scientific and technological side of industry; (b) representing the Ministry on committees concerned with research and consumer protection on the domestic and international fronts and (c) the co-ordination of the work of the Ministry's food science branches.

Candidates must be of high professional standing and must have a comprehensive knowledge of the general structure of the food industry and wide experience in food science and technology and in related scientific fields.

The appointment may be taken up on a short term contract if this is preferred to the normal established basis. Salary is negotiable up to a maximum of £6500.

Fuller details of this appointment may be obtained by writing to the ***Civil Service Commission, 23 Savile Row, London, W1X 2AA,*** *or by telephoning* ***01-734*** *6010, ext. 229 (01-734 6464 "Ansafone" service after 5.30 p.m.). At all times please quote* ***S/7328/U****. Closing date 31st March 1970. Candidates who have already applied should not do so again.*

(1054)

UNIVERSITY COLLEGE OF RHODESIA

Applications are invited for SENIOR LECTURESHIP OR LECTURESHIP IN DEPARTMENT OF AGRICULTURE. Appointment, available in mid-1970 may be held in one of the following disciplines:

Soil Physics: Applicants should be qualified to teach an introductory course in Physics to agricultural students as well as Soil Physics to students specialising in Soil Science. There are interesting opportunities for research in irrigation, the effect of tillage and the mechanics of soil erosion.

Crop Science: Applicants should be qualified to participate in teaching crop ecology and Physiology and Crop Pasture Production and to carry out research and to supervise that of postgraduate students.

Animal Science: Applicants should be Veterinarians or Animal Physiologists qualified to teach and carry out research in the spheres of either Bacteriology/Animal Health or Animal Physiology/Beef Cattle Production.

Salary scales: Senior Lecturers, $R5,616 by $R240 to $R7,536; Lecturer Grade I, $R4,968 by $R216 by $R5,832; Grade II, $R3,624 by $R192 to $R4,776 ($R1 = 11s. 8d. sterling). Family passages and allowance for transport of effects on appointment. Installation loan of up to half of one year's salary if required. Assistance with accommodation for three years for persons recruited from outside Rhodesia. Sabbatical and triennial visits with travel allowance. Superannuation and medical aid schemes.

Detailed applications (six copies), naming three referees by April 10, 1970, to Inter-University Council, 90/91 Tottenham Court Road, London, WIP ODT, from whom particulars are available. (1080)

AGRICULTURAL RESEARCH COUNCIL

INSTITUTE FOR RESEARCH ON ANIMAL DISEASES

COMPTON, NR. NEWBURY, BERKS

A new appointment has become available in a group studying host-pathogen relationships and other aspects of disease processes. The successful applicant would have a large measure of choice of research in relation to livestock kept under intensive methods of production. A veterinary qualification is desirable and previous experience in a relevant field such as pathology, histochemistry, immunology or microbiology, would be an advantage. Appointment in the Scientific Officer or Senior Scientific Officer grade with prospects of promotion. Superannuation under F.S.S.U.

Applications should be sent to the Secretary, quoting reference 113, together with the names of two referees, not later than April 14, 1970. (924)

UNIVERSITY OF GLASGOW

ST. MUNGO (NOTMAN) CHAIR OF PATHOLOGY

The Board of Curators invite applications for appointment to the St. Mungo (Notman) Chair of Pathology (at the Royal Infirmary), which will become vacant on August 1, 1970.

Applications (twenty copies), with the names of three persons to whom reference may be made, should be submitted not later than April 8, 1970, to the undersigned, from whom further particulars may be obtained. In reply please quote Ref. No. 1000-M.

ROBT. T. HUTCHESON,
Secretary of the University Court.
(1015)

BEECHAM RESEARCH LABORATORIES

BROCKHAM PARK, BETCHWORTH, SURREY

have the following vacancies:

IMMUNOLOGICAL TECHNICIAN

who is required to join a team of scientists working on projects connected with Immunosuppression. The work involved would include responsibility for evaluation of novel biochemicals as agents for the modification of the immune response.

Age is immaterial but the candidate, either male or female, would be expected to possess O.N.C. or A level qualifications in a Biological subject. Previous experience in animal work and/or Haematology preferred.

ANIMAL CARE ASSISTANT

A young person is required to join a team of scientists working on certain aspects of virus disease in experimental animals. No qualifications are required but I.A.T. training would be an advantage and opportunities would be given for further study. The person appointed will be expected to handle small laboratory animals, including feeding and maintenance, as well as some laboratory work. Possession of a Home Office licence would be an advantage.

Beecham Research Laboratories is part of the Beecham Group and is situated in a pleasant area of Surrey within easy reach of London. The successful applicants will qualify for the Group's generous profit-sharing and non-contributory pension and life assurance schemes. There are excellent dining facilities and a flourishing sports and social club.

For both these positions, applicants, stating briefly age, qualifications and experience, should apply in writing to the Personnel Officer, or telephone BETCHWORTH 3202, Ext. 83.

(1085)

OXFORD UNIVERSITY

BOTANY DEPARTMENT

Applications are invited for two posts of DEPARTMENTAL DEMONSTRATOR (equivalent to Assistant Lecturers elsewhere but with opportunities for College tuition) to begin in October, 1970:

(1) Appointment for up to three years in the first instance. Candidates should be interested in Genetics of Flowering Plants.

(2) Appointment for one year. Candidates should be interested in the experimental systematics of Flowering Plants.

Salary up to a maximum of £1,515 per annum.

Applications (or inquiries) should be sent with the names of two referees, to the Administrator, Botany School, South Parks Road, Oxford by March 25, 1970.

(1044)

UNIVERSITY OF HOHENHEIM

STUTTGART, W. GERMANY

CHAIR OF POPULATION GENETICS

An der Universität Hohenheim ist ein neugeschaffener ordentlicher Lehrstuhl für Populationsgenetik zu besetzen. Der Lehrstuhlinhaber soll die experimentelle und theoretische Populationsgenetik in Lehre und Forschung vertreten.

Interessenten werden gebeten, ihre Bewerbung hit Lebenslauf und Publikations-liste bis zum 31. Mai 1970 einzusenden an den Vorsitzenden der Berufungskommission, Prof. F. W. Schnell, Universität Hohenheim (LH), 7 Stuttgart-Hohenheim, Postfach 106. (1100)

Robertson Research International Limited

Further expansion in the United Kingdom and overseas has produced additional vacancies for both senior staff with up to ten years industrial experience, and for students graduating in 1970, in the following divisions:

Analytical Chemistry
Civil Engineering
Library and Information Office
Metallurgy
Micropalaeontology
Mineral Economics and Statistics
Mineral Geology
Mining Engineering
Petroleum Geology
Rock Mechanics
Sedimentary Petrography
Soil Mechanics

All permanent and pensionable appointments with incremental salary scales. Overseas allowances appropriate to different areas when operating outside United Kingdom. For further details apply to Personnel Officer, Robertson Research International Limited, Tyn-y-Coed, Llanrhos, Llandudno, Caernarvonshire, United Kingdom.

(1087)

UNIVERSITY OF STRATHCLYDE

Department of Biochemistry

RESEARCH ASSISTANT

Applications are invited for the above post in an M.R.C. Research Group studying biochemical aspects of uterine metabolism.

Applicants, with postgraduate experience, who possess either a first degree or have postgraduate experience in Biochemistry, should have interests in either: (a) nucleic acid metabolism, or (b) protein fractionation, or (c) study of interaction between chemical agents and macromolecular substances.

The appointment will be for a period of five years in the first instance. Commencing salary £1,200 to £1,300 per annum with F.S.S.U.

Applications (quoting R5/70), to Professor P. J. Heald, Department of Biochemistry, University of Strathclyde, George Street, Glasgow, C.1, from whom further particulars can be obtained. (1076)

AUSTRALIAN NATIONAL UNIVERSITY

RESEARCH SCHOOL OF PHYSICAL SCIENCES

TECHNICAL OFFICER/SENIOR TECHNICAL OFFICER

DEPARTMENT OF GEOPHYSICS AND GEOCHEMISTRY

Applicants should have experience in quantitative X-ray Fluorescence analysis and will be responsible for the operation of this facility within the Department.

Salary will be within the following ranges depending upon qualifications and experience: Technical Officer Grade I, $A3,475 to $A4,285 per annum ; Technical Officer Grade II, $A4,283 to $A4,553 per annum ; Senior Technical Officer, $A4,684 to $A6,032 per annum (limits only). In addition a salary loading at the rate of $A200 per annum is payable to Technical Officers for an approved University degree or $A100 per annum for certain recognised Technical College diplomas or membership of a professional body recognised by the University. Assistance with passages and accommodation will be provided. The successful applicant will be required to undergo a medical examination.

Written applications, quoting reference number 70040, should be forwarded to the Registrar, Australian National University, Box 4, P.O. Canberra, A.C.T. 2600, Australia, with whom applications close on April 20, 1970. (897)

POSTGRADUATE POSITIONS IN PHYSICS

QUEEN'S UNIVERSITY
KINGSTON, ONTARIO, CANADA

Research and Teaching Assistantships are available to postgraduate students, both theoretical and experimental, in the fields of solid state physics, nuclear physics, low temperature physics, and radioastronomy. Special experimental facilities include: equipment for ultra high vacuum, magnetic resonance, microwave spectroscopy, luminescence studies, and for electron structure studies of metals by positron annihilation; a 3 MV Van de Graaff positive-ion accelerator, and use of the MP Tandem at Chalk River; a 60-ft. radio-telescope and use of the 150-ft. radio telescope at Algonquin Park. Financial assistance in a combination of Scholarships and Teaching and Research Assistantships is provided in the range $3,500 to $5,000 per annum.

Postdoctorate Fellowships are available in the above fields.

Letters of application, requests for brochures and further information should be addressed to Professor A. T. Stewart, Head, Department of Physics, Queen's University. (1058)

Nature in North America: The *Nature* office in Washington DC has opened and contributors in the United States and Canada are invited to submit manuscripts for publication either to the address given below or to the present London office. The intention is that each office will be able to answer inquiries about all manuscripts and other matters. This is one of several steps by which it is hoped to provide a better service for readers and contributors.

London Office
4 Little Essex Street,
London WC2.

Why Pye Chromatography

The crowning success in the design of complex analytical instruments is the achievement of simplicity. You will find it in Pye Analytical Gas Chromatographs.
Take the simple, functional glass-to-metal seal, for example. It makes column changing quicker and easier, improves sensitivity by reducing contamination of the gas stream and pushes the effective working temperature of glass columns up to 350°C.
Pye gas chromatographs are easy to use because we design them to give you what you want in instrumentation – accuracy, reproducibility, flexibility, simplicity.
Two systems are available, both with a wide range of optional modules—
The Pye Series 104 Chromatograph for research or routine work, with many accessories including wide-range amplifier and auto-solids injection . . . and the Pye Model R Research Chromatograph with modular colum oven, unique "total-loss" cooling system and simultaneous two column multi-detector operation.
To learn more about Pye chromatography including industrial instrumentation, the GM60 Gas Chromatograph-Mass Spectrometer system and the DP90 Datac computerised chromatograph system, write or 'phone today.

'MICHROME'

STAINS & REAGENTS FOR BIOLOGY

Acridine orange, Aquamount, Fluormount, Lipid crimson, Matamount, May-Grünwald, Leishman, Giemsa Toluidine blue, Cresyl fast violet, Papanicolaou stains, Thioflavine S, Brilliant cresyl blue, Nile blue, Pyronin Y, Trifalgic acid, Rhodanile blue, Haplo, etc.

CATALOGUE AVAILABLE ON REQUEST

DYES FOR USE IN ALL INDUSTRIES

RESEARCH & PRODUCTION CHEMISTS: if you are seeking dyes with specific chemical and physical properties suitable for particular manufacturing and/or testing processes you are invited to contact us for supplies.

We hold stocks of an enormous variety of dyes, ready for immediate despatch, including:

Cyanine, Dicyanine, Fast Bordeaux O, Aurantia, Crystal violet, BPC-Scarlet R, BPC, Diazonium salts, Neutral violet, Lacmoid, Nile blue Janus green, Brilliant green BPC, Rosolic acid, Methyl green, p-Ethoxy-chrysoidin, Methyl red, Nitrazine yellow, Pinacryptol green, etc.

INDUSTRIAL RESEARCH ESTABLISHMENTS

are invited to make use of our professional services as consultants on the selection and use of dyes as research and production tools.

Weighing Machines

In Three Volumes

T. J. METCALFE & E. H. GRIFFITHS
Chief Inspectors of Weights and Measures

Part III Electrical & Electronic Applications (GRIFFITHS; 248 pp., 169 illus., £3) has very wide technical interest; in the last 10 years more novel weighers have come out than in the preceding 50. The others (by METCALFE)] are **I Non-Self-Indicating Mechanisms** and **II Semi S-Ind. and S-Ind. Mechanisms;** each £3

BAUER

Precious Stones

— the long-scarce classic work — is now reprinted in two soft-covered volumes with the coloured plates, for 50s. the set (SBN 85264 195 8). Also, as a superb facsimile volume 10 × 8 in. — an opulent gift — at £8 10s. (SBN 85264 185 0)

GRIFFIN

1820

72 pp Cat. from 42 Drury La., London, WC2
has interesting Notes for Authors

Precision Instruments

Announcing—

A New Spectro-polarimeter

The Spectro-C_D ORDograph*

**A combined polarimetric and circular dichroic spectrograph*

An entirely new instrument for the measurement of Optical Rotatory Dispersion and Circular Dichroism over the wavelength range 180–800 nm of samples of optical density in the region 0–5. The data is stored photographically in an exposure time of 1 second for samples of O.D. 2; higher densities take a little longer. Both O.R.D. and C.D. data recorded simultaneously thus enabling studies of rapid reactions to be made in successive exposures. The elimination of electronics gives a low cost, trouble free, highly stable instrument with unique features.

We now have the capacity for aluminising certain types of mirrors, at short notice.

NATURE Volume 225
MARCH 21, 1970

The Next Decade in Space

THE anticlimax after the landings on the Moon has, if anything, been accentuated by President Nixon's statement on the immediate future of the United States space programme (see *Nature*, **225**, 995; 1970). A part of the trouble, unavoidable perhaps, is that the new programme lacks a clear definition of a tangible goal which can match President Kennedy's declaration ten years ago that the United States would go to the Moon "within this decade". To be fair, it is just as well that President Nixon has chosen not to compete on terms like these. A sharp commitment to a specific goal would have been imprudent, and may even have been impossible. Although some extremists have been urging, for example, that a journey to Mars within some specified interval would be a sufficiently tangible goal to keep people working hard for the next decade, and to keep Congress sweet as well, the truth is that a journey to Mars in the next decade would serve no purpose that could not more easily and cheaply be accomplished by the proper design of automatic instruments. This time, there is not even the excuse that such a journey would help to advance the technique of sending people about the solar system. But if it is wise to have relegated the Mars journey to the list of tasks that will be attempted "eventually", it is far from easy to appreciate the philosophy on which the new programme has been put together. Is it simply a ragbag compromise between those who would be off to Mars like a shot if only somebody would provide the money and those who would shut down the space programme tomorrow if they could, spending the money instead on urgent social problems or even just the relief of taxes ?

There is a great need that the principles on which the future of space research is based should be made much more explicit than they are. A useful starting point is a simple empirical recognition that it would be a great mistake, and a great waste of resources, to dismantle the apparatus for space research which has been constructed in the United States in the past decade, chiefly the organization of the National Aeronautics and Space Administration. It is true that if it had not been for the Apollo programme, NASA would not have grown as quickly and would not now be spending more than $3,000 million a year. At the same time, however, it is clear that it would now be impossible for the United States to sustain even the most spartan space programme if NASA were, say, a tenth as expensive as it is at present. And as things are, the continuing cost of housekeeping within NASA is substantially more than that. The chances are that it would cost approximately $1,000 million a year simply to keep NASA ticking over, to maintain its laboratories, its capacity to brood about what might be done next and to preserve an efficient organization for collecting data from the Earth satellites which already exist. But with such a machine in being, is it not at least reasonable to spend twice as much again, making a total of $3,000 million a year, to allow the organization to include a modest amount of innovation in its programme ? This line of argument is as good as any other advanced in the past few days to justify the scale on which the forward plans of NASA are now determined. This sum of money, after all, is a mere 1·5 per cent of the United States budget and merely 0·3 per cent of the GNP. It is also a politically realistic sum of money—there would be great weeping in Congress in what is, after all, an election year if more of NASA's establishments had to be closed down—the shutting of the Electronics Research Center at Cambridge, Massachusetts, has shown how local prosperity depends on NASA establishments, while it would take a veritable pied piper to charm a substantially larger sum of money out of the Administration in the present climate of financial opinion. To be sure, NASA is badly served by its authorization committee in the House of Representatives, which regularly wastes the chance to make a constructive appraisal of what the agency is up to for the sake of foolish and empty gestures of goodwill such as the voting of unwanted and unspendable money (see page 1097), but it would be a splendid starting point in working out a strategy for the next few years to say that NASA should be asked to make the best it can of an annual budget which is not very different from the $3,500 million which it is likely to be getting for the coming fiscal year.

The question, then, is what should NASA do on such a pension ? This, plainly, is the kind of question that Mr Nixon sought to answer when he put together the package of new developments which he described last week. The first thing to be said is that the new programme—strategy is too strong a word—is too diverse. President Nixon said that he wants to continue with the exploration of the solar system, the application of Earth satellites to useful tasks such as telecommunications, the development of cheap methods of getting into and out of space (which to NASA means the space shuttle), the development of the techniques of extended spaceflight (which implies the experimental space station) and involvement of nations other than the United States in this ambitious programme of development. For the sake of some of the newer fun and games, NASA is plainly willing to let some urgent needs be overlooked. There is, in short, a danger that even though the panic to reach the Moon has now been exorcised, NASA will still find itself having to give less attention to the things it could accomplish well.

Scientific exploration is a case in point. President Nixon was right to say that a better knowledge of the solar system should be one of the objectives in the coming decade and there is, of course, great elegance in the scheme for sending a rocket to the outer planets by using the chance coincidence of planetary positions in the eighties to make the journey to Pluto with a less powerful rocket than would ordinarily be needed. The problem, unhappily for the new programme, is that NASA does not have a monopoly of the exploration of the solar system, and that there has never been a serious attempt to balance the very large sums of money to be spent on the grand tour, and, for that matter, on the complicated telescope to be carried on the first space station (see *Nature*, **225**, 994; 1970), against the much more modest sums of money being spent on other kinds of basic research in this field. Certainly it is irrational that these ventures should be launched at a time when the United States is being waywardly deprived of radio telescopes, to name only one way in which the cause of scientific exploration of the solar system might be advanced. It must also provoke questions that NASA could afford $145 million in 1969 for physics and astronomy, when the pressure of the Apollo programme was intense, but has only asked for $127 million in the coming year, when ordinary people would have thought that there might be a chance to fill in some of the gaps left behind in the scamper to the Moon.

There is also a danger that the plans for the better application of Earth satellites which have now been handed down as if by Moses will spend too little effort on important work. To be fair, the programme for the year ahead does include the development of the improved weather satellites, to be launched in 1972 and 1973, which will make it possible to recover a detailed temperature profile in the atmosphere of the Earth and thus to provide numerical data of a kind which may yet provide a basis for an international weather forecasting system. The value of the programme which may make this possible has been a welcome surprise, and a prudent NASA will be ready to commit extra funds to schemes like this in the years ahead. But why should "budgetary restraints" have forced the postponement by a year of the two satellites called ATSF and ATSG, originally to have been launched in 1972 and 1973 respectively? These, after all, will provide the first tests of the feasibility of air traffic control, millimetre waves and even lasers in telecommunications and, for that matter, the experimental use of satellites for educational broadcasting in India. If, as President Nixon says, one objective for the next few years must be the speedy exploitation of such uses as there may be for Earth satellites, surely these instruments should have been given a place closer to the Sun. (By comparison, Earth resources satellites are still nebulous entities, hardly deserving of the over-sharp talk still frequently lavished on them.) If President Nixon and NASA wish to be taken seriously, this is also a field in which good sense requires that useful jobs which can be done should urgently take priority over the more speculative ventures also now included in the shopping list.

But should there not be some consideration for the continuing development of the technology of space research and even of space travel? Having travelled as far as this, it would obviously be foolish to let the techniques ossify, yet, even so, it is a great mistake that President Nixon's statement should have made conspicuous the two particular notions of cheaper space travel (implying re-usable launchers) and extended space travel. To be sure, these are schemes which have been widely talked of for much more than a year, and were explicitly mentioned in the report of the Task Force which advised the President on what should happen next. It is also the case that NASA has already worked hard on both of them—so much is clear from the study on the subject carried out by the staff of the House Science and Astronautics Committee and published on February 12 this year. But are these schemes as urgent as they are being made to seem? What damage would be done if the space station were postponed a year? Most probably, only the potential contractors would notice the difference. And is it really acknowledged that NASA will have by the late seventies the need to launch the thirty or so satellites a year that will be necessary to repay within five years the difference between the cost of developing the shuttle rather than using rockets which already exist? And does not this imply that by then the budget of NASA should have risen substantially, so that the cost of making rockets is only a small part of the total? Even though this estimate of the point at which the shuttle project will break even depends on the assumption that military interests will also need to launch some thirty 25,000 pound payloads into orbit every year, which lends the space programme a sense of importance which it has been able to manage without so far, this is quite a tall order. Has the Administration really appreciated how great will be the cost of making the new space shuttle cheap?

These uncertainties are one reason why NASA is mistaken in hoping to kindle international interest in collaboration on the shuttle. Dr Paine is probably right in believing that there must be some way in which space could become a focus for international cooperation, but he seems bent on offering his potential partners the wrong end of the stick. It is unfortunately a plain fact that the journey to the Moon has not budged the industrialized nations which are the most likely collaborators in the new space programme from their pragmatic view that the best ventures are those most likely to yield some economic benefit. Telecommunications, weather analysis and air traffic control (with navigation as a kind of sideline) are the only immediate candidates. In each case, however, successful collaboration would require not merely a thorough sharing of costs but joint planning as well. The kinds of collaboration of which Dr Paine is so far rightly proud raised only a few of the thorny problems which must be created by programmes of collaboration which consist not simply of the parcelling out of work but the permanent commitment of hopes as well as of resources to some common venture. There is every reason why the United States should take the initiative in this field, but it should begin at the humdrum end of the spectrum. There is no reason why NASA should not be able to look forward to a time when it is a kind of international public service agency, living as much off fees for services provided as from the bounty of a taxation-conscious Congress.

This is probably the sense in which NASA and the Administration have most seriously misjudged the present need. By now, there is probably good reason to believe that space research and exploration has come to stay. Such benefits as there may be will be diverse and scattered. In the long run, however, this implies that no single agency within one state can hope to remain a dominating influence. Much of what is now considered NASA business will eventually be regulated by private or international organizations. But this means that NASA should be working hard to divest itself of its responsibilities. It should also be vigilant in making sure that what can be done properly is done well. The most disappointing feature of the new space programme is that it seems to be somewhat aimlessly intended to keep the machine in being without specifying what it is intended for.

Straight and Narrow

THERE is nothing openly wrong with Mr Callaghan's bill on the control of drugs. The notion that pushers should in future be dealt with more severely than possessors is sensible enough, and fourteen years in gaol is not too severe a penalty for those who make a business of addiction. The attempt to relate the terms of imprisonment which drug possessors will in future risk to the pharmacology of the materials on which they are dependent is less successful.

What precisely is the logic by means of which it has been decided that the possession of heroin and LSD should both incur the risk of seven years in gaol, that cannabis should rate a mere five and that the amphetamines and pep pills derived from them should be worth just two years? The World Health Organization, from which this classification is ultimately derived, was right to say that LSD is as great a hazard to the health of an individual as heroin or opium. The social risk, by contrast, is of a quite different order. Presumably these sentences are meant to be deterrents, ways of protecting people from themselves and ways of restricting the market for narcotic drugs—if the potential customers can be frightened off, there will be less business for the pushers. Certainly there is no reason to hope that a prison sentence will actually cure an addict (in the old-fashioned sense) of his addiction. But in circumstances like these, it would have been worth the trouble for the Home Office to have tried to relate these prison sentences not so much to the pharmacology of the material concerned as to the manner in which it is used. Why not, in other words, let judges and magistrates know explicitly that some degree of restraint in the way in which the drug of choice is shared with friends and acquaintances should be a substantial mitigation of the misdemeanour, for example? The danger, as things are, is that the arithmetic of the sentences now spelled out will only perpetuate the arbitrariness in sentencing and even prosecution which has been one of the most harmful features of the British handling of drugs in the past few years. This is one of the points to which the House of Commons should pay close attention.

Most argument in the weeks ahead is, however, very likely to be concentrated on the proposal that doctors who systematically over-prescribe dangerous drugs for their patients should be banned from prescribing these materials. This is an extremely tricky proposal, as the Home Office is no doubt well aware. Ever since the Brain Committee, it has been well understood that the so-called "English system" of dealing with drug addiction, under which the drug-dependent were given maintenance doses by their physicians, finally broke down when a handful of doctors were found to have lavished unwarranted quantities of narcotics on their patients. One difficulty, however, is that of knowing how to define what "over-prescribing" means. Is it now to be supposed that physicians will be required to vouch not merely for the physical needs of their patients for materials such as the amphetamines but for their honesty as well? And what are the implications of an arrangement under which medical practitioners are barred from some kinds of medicine? There are genuine difficulties in a system under which the government, even with the approval of a medical tribunal, has the right to curtail a doctor's licence. How can a general practitioner function properly if he is unable to treat his patients for specified conditions? And is there even a danger that the next step will be to prevent surgeons with bad records at some kinds of operations from repeating their performance? The trouble is that any attempt to restrain doctors from socially disagreeable practices must necessarily involve the kind of qualitative judgment of a doctor's work which society has usually avoided. Especially because of the retributory air which the new proposal carries, any alternatives to this proposal which the House of Commons can devise would be most welcome.

No amount of patching in the House of Commons can, however, turn the new Home Office bill into the positive measure which might have some lasting influence on the social problems of drug dependence. The most urgent need is for better ways of treating drug dependence on heroin and such hard drugs. Not merely research but facilities are needed. Everybody is aware of the haunting difficulty of this problem, but there are some hopeful experiments—the use of methadone as a substitute for heroin, for example, and the several experiments in the United States in which people who are dependent on drugs help each other to escape from their problems. There is a danger that the new array of penalties, devised with good intentions, may make it even harder than it has now become to treat drug dependence as if it were what it is —a physical condition.

Mr Callaghan is not the kind of man who takes risks in what will almost certainly be an election year. "Jim the Pot" would be an awkward label on the hustings in Cardiff. But is it wise to avoid the illogicality of a system under which commonly used but damaging drugs such as alcohol, barbiturates and even nicotine (or the carcinogens which accompany it) are permitted, but materials such as cannabis carry the risk of two years imprisonment? As a temporary expedient, such as the ban which King James I once imposed on the consumption of coal in London, it may have some value. In the long run, it will prove to be unstable.

100 Years Ago

He was about to apply his spectroscope to the observation of a solar prominence when his attention was attracted to certain shadows traversing the disc of the sun, which became bright streaks when they had passed beyond it. At first he thought these appearances were due to sparks in the tube of the telescope, but the phenomenon lasted too long for this explanation to be available. He next thought that perhaps a system of meteors might be in transit, and prepared to subject the phenomenon to careful scrutiny. The equatorial was set in motion, the sun's disc being projected on a screen. The shadows were seen persistently traversing the solar disc, but at different velocities, the larger ones travelling most swiftly. There appeared to be two streams. He noticed that when the sun was in focus the objects were indistinct, and that they appeared very distinctly when he focussed on a distant cloud. At length, while he was attentively scrutinising the phenomenon he saw one of the objects come suddenly to a standstill, and then whisk off in a different direction; and then he perceived that the phenomenon he had been examining with such anxious care was not in reality an astronomical phenomenon at all, but consisted merely of a flight of locusts. He considered, however, that not only was the existence of so enormous a swarm of locusts as the duration of the stream indicated, an interesting fact in itself, but that we might find in the occurrence the explanation of many statements which had been made respecting meteors supposed to have transited the sun, and also of some peculiarities noticed by astronomers in America during the total eclipse of last year. Mr. Stone said that it was important when appearances of this sort were noticed that the observer should examine, as Lieut. Herschel had done, whether the objects seen in transit required the same focus as the sun. This was the best way of determining whether the objects were terrestrial or not.

From a letter written to Professor Alexander Herschel by his brother and read to the Royal Astronomical Society (Nature, **1**, 543, *March* 24, 1870).

OLD WORLD

COMPUTER POLICY

Computer Society's Lack of Push

ALL aspects of the British computing scene were covered during the appearance of the British Computer Society before subcommittee D of the House of Commons Select Committee on Science and Technology last week. Eager for change, the society in its evidence talked of the poor state of computer education in Britain, the doubts surrounding government policy, and the uncertainty that clouds the future prospects of British computer firms. But enthusiasm alone is not enough, and the subcommittee under the chairmanship of Mr Airey Neave was disappointed that the society has not been more forthright in pressing its views on the government.

The deputy president, Mr A. d'Agapeyeff, pleaded the voluntary nature of participation in the society as the reason why the society's recommendations on education could not be backed by more research. In particular the society was taken to task for presenting a memorandum to the subcommittee talking of computer courses "offered by bodies reputable and disreputable" without being prepared to back up its allegations with evidence.

The British Computer Society nevertheless represents most sections of the British hardware and software industry as well as user organizations, and is the nearest the subcommittee has yet come to a disinterested party in its investigation of the British computer industry in the seventies. Although some of the society's recommendations were dismissed by Mr E. Leadbitter as a series of generalizations, the witnesses were prepared to go further when speaking as individuals. Professor S. Gill startled the subcommittee with his ideas for pruning the jungle of departments which deal with computer purchasing for the government. These include the Stationery Office, the Civil Service Department and the Ministry of Technology, which has the final say. Professor Gill thought it would be a good idea to remove the Mintech link from the chain. This would avoid the clash of interests caused by competition from a foreign computer, between the ministry, which also has the job of fostering the British computer industry, and the Civil Service Department, which is responsible for the efficient working of the civil service.

On the subject of education and training the society was keen to see changes from school level upwards. University training was called "formal and irrelevant", chiefly because the universities provide little expertise in the growing field of business computing, although the witnesses agreed that this is a difficult area for the universities to cover.

The society had a lot to say about government policy. In particular it complained that the government could be more aware of the importance of software, that departments are too cautious (citing the slow rate of installations in the Inland Revenue) and, echoing earlier witnesses from IBM (UK) and from Honeywell, that there should be less hypocrisy over the policy of favouring British computer manufacturers. The society said it should be consulted by government on matters of computer policy. But the subcommittee found the society's lack of initiative in making representations to the relevant departments, as other professional bodies do, an unimpressive comment on this suggestion.

NUCLEAR POWER

Fuel Company Announced

BRITAIN'S nuclear fuel business is to be handled by a new government controlled company, British Nuclear Fuels Ltd, according to a bill put forward by the Minister of Technology, Mr Anthony Wedgwood Benn, published last week (*Atomic Energy Authority Bill*, HMSO, 3*s*). The AEA's smaller but buoyant radio-isotopes business will also be established as a separate company, to be known as The Radiochemical Centre Ltd.

The setting up of British Nuclear Fuels is the second stage of the reorganization of the nuclear industry that was begun by Mr Benn in 1968 and represents the next step in switching from a research-oriented to a market-oriented industry. The third stage of the reorganization was outlined in the green paper, published in January this year, which envisaged the merger of the research side of the AEA with other research establishments of the Ministry of Technology to form a new British Research and Development Corporation.

Five establishments of the AEA will be transferred to British Nuclear Fuels if the new bill is passed. These are at Capenhurst in Cheshire, Calder Hall in Cumberland, Chapelcross in Dumfriesshire, Springfields in Lancashire and Windscale in Cumberland. Radiochemical Centre will be comprised of the radiochemical centre at Amersham in Buckinghamshire and a contingent from the Atomic Energy Research Establishment at Harwell. BNF will become the British component in the joint scheme negotiated by the governments of the Netherlands, Britain and West Germany for the production of enriched uranium by the gas centrifuge process, and will assume a minority shareholding in the two reactor consortia, TNPG and BNDC.

There is not expected to be much opposition to the setting up of the fuel companies. The present British market for nuclear fuels is estimated at £25 million, and is expected to rise to £100 million by 1980. The world market is likely to have exceeded £1,000 million by 1980, and the need for a strong commercially oriented body to manage this expanding business is widely recognized. Nuclear fuel is, of course, the most lucrative side of the nuclear power business. Sales of radio-isotopes are also growing, with half the radiochemical centre's £4 million trade coming from overseas.

The exact composition of the BNF shareholding is not yet known, but companies believed to be interested in participating include Imperial Chemical Industries, Rolls-Royce and Rio Tinto Zinc. Mr Benn is known to be in favour of cooperation between government and private industry in this sort of venture, a view which may, however, be challenged by the opposition spokesman on trade and technology, Sir Keith Joseph, when the bill is debated in the House of Commons. The bill was introduced in the House of Lords last week, but even the most optimistic estimates make it unlikely that either of the companies will start operating before October.

DRUGS

Hard and Soft Distinguished

STIFFER penalties for drug "pushers" and stringent provisions to prevent doctors prescribing "irresponsibly" are the main features of the Home Secretary's comprehensive new drugs bill. Controlled drugs are divided, according to their harmfulness, into three groups so that for the first time "hard" and "soft" drugs such as heroin and cannabis are treated differently (*The Misuse of Drugs Bill*, HMSO, 5*s*).

The bill assigns different penalties for misuse in each of the three controlled groups. The group considered most dangerous includes heroin, morphine, cocaine and LSD, and the penalties for producing or supplying these "Class A" drugs are up to fourteen years imprisonment and an unlimited fine. The penalty of seven years for being in possession of these substances is less than the present maximum sentence of ten years for drugs included under the Dangerous Drugs Act, 1967, a concession which reflects the present practice in the courts of imposing lighter sentences on drug users than on drug pushers.

Amphetamines, cannabis and codeine are bracketed together as "Class B" drugs. Maximum penalties for pushing these drugs are still fourteen years imprisonment and a fine, but the penalty for illegal possession is down to five years. Sentences for possession of the least harmful group of drugs ("Class C"), which includes some of the less dangerous stimulants, are up to two years imprisonment and a fine. Barbiturates are not specifically carried by the new bill but their position is under review.

A new power proposed in the bill is that of adding new drugs to the controlled list as soon as it seems that they may become dangerous. The danger would be assessed by an advisory committee and a panel of experts, but the formal procedures involved in getting a drug classified could take place quite quickly, within a few weeks if necessary. The present system of putting new drugs on the list requires international agreement and can take up to two years.

Another new provision in the bill concerns information on the supply of drugs. In regions where the misuse of drugs is causing "social problems", the Home Secretary can ask doctors or pharmacists for details of the quantity of drugs and the number of prescriptions they have supplied.

SATELLITE

SRC Advertises its Vacancy

THE Science Research Council has strange ways of announcing its achievements. Advertisements in the daily press last week (*Daily Telegraph*, March 13) for a satellite engineer to work on a new satellite in the Ariel series concerned with cosmic X-rays have revealed that at least project definition and feasibility studies are complete for the most attractive British satellite payload yet attempted. This is part of the long-standing US-UK cooperative programme (drawn up in 1959) according to which NASA provides the launch and Britain the scientific ideas and hardware. So far three satellites have been launched and one more is in the pipeline—called UK-4 until 1971 when a successful orbit will rechristen it Ariel-4.

As the programme has progressed, the partition of activity has become more equal. For Ariel-3 British industry has undertaken design and construction of the satellite body. The fourth in the series is to carry an American experiment in addition to four British (see *Nature*, **223**, 3; 1969). This hospitality is being repeated on the UK-5 stellar X-ray satellite.

The six experiments planned for UK-5 are designed to complement each other. All are concerned with stellar X-rays. A spin-stabilized design enables both broad sky surveys and precisely pointed detailed observations of individual sources to be carried out from the same vehicle. The four experiments concerned with individual sources will look along the spin axis of the satellite which, by means of fine gas-jets, can be aimed with an accuracy of one degree to any point in the sky. The two survey experiments look out of the side of the spinning satellite so that between them the whole sky will be covered. The US experiment, a survey instrument from the Goddard Spaceflight Center, has a wide fan-shaped field of view forward and aft of a Leicester University survey instrument.

To date, some 50 X-ray sources have been observed but less than ten of these have been precisely fixed. Precise location of individual sources is the predominant problem at present. Some X-ray sources are thought to be short-lived or highly variable so that it will be useful to compare the Goddard and Leicester survey findings with data from an American X-ray survey satellite (SASA—small astronomical satellite A) which is to be launched shortly.

A fine-pointing instrument designed by University College, London, is intended to obtain positional accuracy of individual sources to within 1 arc minute. Another University College experiment employs a proportional counter which is expected to obtain high sensitivity but low resolution of the spectra of individual sources. A complementary experiment mounted by Leicester University makes use of a crystal spectrometer giving low sensitivity but high resolution of spectra and also a measure of polarization.

The Imperial College experiment extends the observations of X-ray sources to energies in the Mev range. It derives from techniques using a shielded scintillation counter developed by the cosmic ray group for observing magnetosphere particles.

Because all the work has been carried out from brief rocket flights, the total amount of observing time of X-ray sources probably does not exceed 3 hours. Satellite observations should increase the sensitivity by a factor of 100, thereby substantially increasing the number of known sources. At present teams at University College and Leicester are keeping British work in X-ray astronomy to the fore.

The development by Elliott Automation, Frimley, of a refined gas-jet system for obtaining fine alignment of instruments on target in space has played its part in maintaining British success in this exacting new field. This system is in view for controlling the attitude of the UK-5 spacecraft. Elliott Automation is now part of the GEC complex and another member of the group, GEC–Marconi, is the prime contractor for the satellite expected to be launched by an American Scout rocket in 1973. Because the ride for the Goddard experiment is being offset against launch costs, the total cost of the project to Britain is only £2 million.

ARCHAEOLOGY

The Amsterdam and the Lawyers

THE manifestations of underwater archaeology have come late to this country. Now that worthwhile material is emerging it is clear that we have neither the law nor enough suitably trained people to cope, which is a curious situation for a traditionally maritime country. The predicament is highlighted by the romantic case of the Amsterdam, the fully laden Dutch East Indiaman that has been stuck in the Hastings mud since 1749, and received its most complete exposure for 221 years in the press last week.

It is beginning to be appreciated that, properly excavated and preserved, the Amsterdam offers a unique view into trading life and conditions at sea in the mid 18th century. No ship—much less a merchant ship—is known from such an early period with virtually all its contents intact and even stowed in the positions they were placed at loading. Not even Sweden's 17th century flagship Wasa can claim this because, being half empty when she sank, she heeled right over, and the final location of objects found within her on raising bore little relation to their original position.

Yet at present none of this has any protection by law. The salvage law (which goes back to the Merchant Shipping Act, 1894) tends to encourage vandalism by rewarding quick recovery of goods regardless of the methods by which they are obtained.

An attempt was made in the Commons last week through a joint-party backbench motion to introduce clauses into the government's current Merchant Shipping Bill which would provide for the protection of historic wrecks by scheduling them like historic buildings. The Merchant Shipping Bill is framed to amend the law as it relates to seamen's pay and conditions of service in line with the Pearson Report, and is not a total revision of the old Merchant Shipping Act. The government spokesman (Mr Goronwy Roberts, Minister of State, Board of Trade) made sympathetic noises but declined to extend the measure to include the protection of historic wrecks. The clauses were withdrawn but may be reintroduced when the bill

Wreck of the Amsterdam, sunk in Hastings quicksands since 1749 and here exposed to the greatest extent in 221 years through a combination of equinoctial low spring tide and mechanical excavators.

reaches the Lords shortly if only to give an opportunity for the Board of Trade to reveal if it has an official inquiry or other action in mind, as seems likely.

In theory, an historic wreck could be scheduled as a public monument under present law. But the Ancient Monuments Board, which is responsible for unoccupied and immobile historic buildings, classes a ship as "a chattel" and therefore not within its purview.

Meanwhile the gaps in the British regulations are becoming a disgrace. Almost all other European maritime nations have introduced legal protection for historic wrecks and cargoes, although few can rival Britain's nautical heritage.

PHYSIOLOGY

Study in Depth

The Royal Navy last week broke the world record for deep diving on dry land by taking two volunteers to an equivalent of 1,500 feet in a pressure chamber. The subjects endured ten hours in an atmosphere of oxygen and helium at 666 pounds/inch^2 (just over 45 atmospheres) and spent the next eleven days in a gradual mock ascent. The exercise was organized by Dr Peter Bennett of the Royal Naval Physiological Laboratory, who seems to have achieved his aim of disproving the "helium barrier" at 1,200 feet which was thought to represent the greatest pressure at which an oxygen–helium mixture could be breathed. There is no sign yet of any physiological limit for diving, and at least a further 300 feet of the sea are now opened up to explorers who take the requisite precautions.

Besides the intrinsic interest of seeing what depths the human frame can attain, the experiment has provided an opportunity for studying the tremors and dizziness often suffered when high-pressure helium mixtures are breathed, and at the same time has made possible a wide range of physiological observations which have yet to be analysed.

Because of the experimental nature of the exercise, frequent safety checks were made during the descent; the subjects paused for 24 hours at a time in atmospheres corresponding to 600, 1,000 and 1,300 feet, and made intermediate one-hour halts at 1,100, 1,200 and 1,400 feet. One of the subjects was temporarily affected by helium tremors after changes of pressure, but the other only suffered from occasional dizziness. It seems that limitations of time rather than physiology are the chief obstacle to really deep dives. Descents must be gradual to allow divers to acclimatize to each small increase in pressure, and there is also the need to decompress very slowly on the way up. Even with the eleven days that the experiment allocated to resurfacing, one of the subjects suffered slightly from "bends" so that the decompression time had to be extended by several hours.

The belief in a helium barrier came from a Franco-American simulated dive in 1968. When the subject reached 1,190 feet he found himself falling asleep unless he stayed constantly active, and the pressure was reduced after only four minutes because his EEG showed serious abnormalities. Dr Bennett says that the stimulus for his own test came from a later exercise in which 1,150 feet was held successfully for five hours. People at the naval laboratory became convinced that so marked a difference was unlikely to occur over just 40 feet and that another trial was needed.

DISEASE

Mortality Patterns

People who live south of a line joining the Wash to the Severn have a better chance of living to a ripe old age than those living in the north. But what is the significance of that information? Professor G. Melvyn Howe, of the University of Strathclyde, whose revised and enlarged edition of the *National Atlas of Disease Mortality in the United Kingdom* (Nelson, 105*s*) is published this week, believes that the mapping of diseases may provide a useful tool in understanding and pinpointing underlying factors associated with disease. The regional variations may help to exhibit associations with climatic conditions, type of soil, pollution, or other physical parameters, or they may reflect the habits or mental tensions which are more common in certain areas. In a relatively immobile population, area differences in mortality could also reflect hereditary mechanisms for some diseases.

The patterns certainly show that mortality from all causes is well above the national average in parts of the north of England and Scotland, while the south coast and most of southern England are relatively healthy. Salford earns the unenviable title of the unhealthiest town in the UK, and other disease black spots are central Scotland, the mining towns of South Wales, and the rest of Merseyside and South Lancashire.

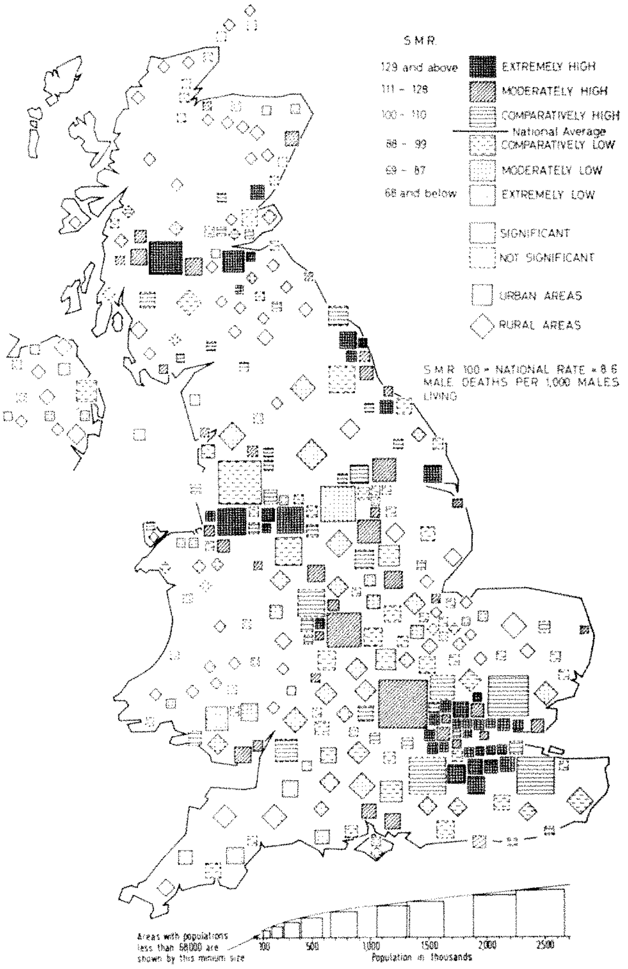

Fig. 1. Mortality rates for cancer of the trachea, lung and bronchus (males). *National Atlas of Disease Mortality in the United Kingdom*, p. 110.

London fares relatively well in the health league, although the boroughs of Southwark, Shoreditch, Stepney and St Marylebone have mortality rates well above the national average. In contrast, Bournemouth seems to be the healthiest town in the UK. These variations seem to suggest that disease mortality is highest in areas of poor housing and heavy industry.

The variations in mortality from specific diseases are even more striking. The similar distribution of high mortality from lung cancer for both males and females suggests that an environmental factor is particularly important in this disease. As might be expected, the disease is more common in areas of heavy industry, the four areas with the highest incidence being greater London, Merseyside, northeast England and Central Scotland. A different environmental factor seems to be operating in the case of diseases of the circulatory system. Although Professor Howe does not rule out the possibility of genetic factors and regional habits, his maps seem to support the theory that there is an inverse correlation between high incidence of these diseases and the hardness of the water supply. A particularly interesting finding is that the coronary mortality in Birmingham, which has soft water, is below the national average. The Birmingham water authority has neutralized the acidity of its water for several years.

Mortality from bronchitis follows the expected pattern, with the areas of highest incidence being those associated with heavy industry. London, in particular, fares worst in the central boroughs. Although the richer boroughs of London escape many of the diseases associated with poor housing and polluted air, they come off badly in mortality associated with mental stress. In Westminster, Hampstead, Chelsea and Kensington, mortality from suicide is more than twice the national average.

EUROPEAN NUCLEAR POWER

ENEA takes the Pulse

THE application of nuclear power in Europe has lately been going through a period of reappraisal rather than of innovation. This is the verdict of the European Atomic Energy Agency in its report for 1969 which was published last week. Largely because of the economic situation in Europe, the processes of decision-taking in the area of nuclear power are becoming more protracted. But according to the report, these changes in attitude are not greatly affecting forecasts of the growth of nuclear power in Europe.

The European Atomic Energy Agency is, of course, the agency of the OECD which promotes the Dragon high temperature project at Winfrith, the boiling heavy water reactor project at Halden in Norway, and the Eurochemic fuel reprocessing plant at Mol, Belgium. The report notes with pleasure that recent months have seen decisions to continue with each of these projects, all of which came up for renewal recently. As well as supporting other less ambitious cooperative projects, such as the maintenance of a computer program library at Ispra in Italy and a Neutron Data Compilation Centre at Saclay (France), the agency keeps a watching brief over the fortunes of European nuclear power programmes.

Because the demand for electricity has not risen quite as quickly as expected, there has been a slackening in the ordering of new power stations, and this is particularly so in Britain and France, which have so far made the running in the growth of European nuclear power. The report points out that neither lack of confidence in the nuclear power nor concern over uranium supplies, two popular bogies, is implicated.

But the report makes the point that the economics of plants for enriched uranium, such as the British–Dutch–German centrifuge project, are extremely sensitive to the amount of enriched uranium which is to be produced, so that forecasts of demand need to be accurate. Unfortunately the predictions seem to be less certain now than they have been. With the demand for electricity not rising at the expected rate, the estimate of 100,000 MW of nuclear capacity installed in Europe in 1980 is in doubt. This estimate followed from the anticipated need for 40,000 MW of nuclear power by 1975, which with 26,400 MW already installed by half-way through last year implied the ordering of 13,600 MW during the next year or so to meet the deadline. The protagonists of the centrifuge project, who promise to produce enriched uranium competitive with the American product, will no doubt be keeping a close eye on the way the demand develops.

SOVIET UNION

Lightning Communication

from our Soviet Correspondent

THE launching last month of the latest in the series of "Molniya-1" ("Lightning") communications satellites of the Soviet Union, coinciding as it does with the Washington conference on communications satellites, must inevitably draw attention to what may be classed as one of the less publicized achievements of the Russian space programme.

It may well be true to say that in no other country are communications satellites less of a luxury and more of a necessity. The sheer geographical extent of the USSR, sprawled as it is across so many time-zones, has always placed rapid communications at a premium. And since, in spite of the great development schemes of the 1950s, much of the vast area of Siberia is still an emerging rather than a developed region, the problems posed by a satellite communications system have been solved in rather a different manner than in, say, the USA. Indeed, the basic concept of Molniya-1 differs from the American Comsats, since Molniya-1 is not a geostationary satellite, and more than one must be employed if round-the-clock coverage is to be achieved.

Molniya-1 is a heavy satellite, with a reported transmitter power of 40 W. The accepted proportion for communications satellites is that each watt of radiated power corresponds to 2 kilograms of transmitter weight, and that the transmitter weight is about a quarter of the total weight. Thus the Molniya-1 satellites must have a weight of the order of 320 kg.

With satellites of this power, it is possible to use comparatively small ground stations. Under conditions in the Soviet Union, this is a considerable advantage, since a wide network of ground receiving centres can be erected relatively quickly and at comparatively low cost—an important factor when dealing with the rapidly developing areas of Siberia.

In the words of an official bulletin (*Pravda*, July 22, 1969) the Molniya-1 satellites are "intended to guarantee the working of the system of long-distance telephone and telegraphic communications, as well as transmitting the programmes of the central television network of the USSR to points of the 'Orbita' network (the ground stations) situated in the Far North, Siberia, the Far East, and Central Asia".

The Molniya-1 satellites are given a highly elliptical orbit to ensure the maximum transmission time over Soviet territory. The first successfully launched Molniya-1, which went into orbit on April 23, 1965, had an apogee of 40,000 km and a perigee of 500 km, giving it a period of 12 hours and an effective transmission time of 6 to 8 hours. These parameters have apparently proved satisfactory, since the latest Molniya is close to these values with an apogee of 39,175 km and a perigee of 487 km.

One of the most interesting uses of the Molniya-1 satellites has been the transmission of newspapers from Moscow and Leningrad to the Far East. Test transmissions carried out as early as February 1968 proved highly successful. The system of video transmission used has not been published in full; it has been stated, however (*Elektrosvyaz'*, **5**; 1969), that the necessary frequency multiplexing is most simply achieved on the video frequency, for this does not require a special transmitter and eliminates the danger of transient noise in the onboard retranslator of the satellite. It is arranged that the newspaper columns can be transmitted simultaneously with the regular TV transmissions, by the addition at the edge of the TV video signal of a subcarrier modulated by the video signal of the newspaper.

On the expansion of the Molniya–Orbita system, V. P. Minashin, chairman of the governing body of the Ministry of Communications of the USSR, stated in a recent interview that the USSR now has the widest network of "reception points" (ground stations) in the world "especially in sparsely populated and inaccessible regions".

Colour television transmissions were introduced on July 22 last, and experimental exchanges of colour TV programmes between Moscow and Paris proved most promising.

By the end of 1969, 30 Orbita ground stations were to be in operation, covering many of the Siberian "new towns" particularly in the newly opening petroleum and natural gas belt.

An extension to the Orbita network to cover Mongolia is planned as a joint venture between the Soviet Union and the Mongolian People's Republic. This, said Minashin, will pose particular problems in view of the "local climatic conditions and requirements of the country".

Easier, technically speaking, will be another proposed extension—the launching of an "Intersputnik" Comsat system by the Soviet Union in conjunction with the countries of Eastern Europe.

One final refinement of the Molniya-1 should be noted: besides the transmitting apparatus, it has on board a "command-measuring complex" and systems for the correction of orbit and orientation, which are used to bring the satellite from its initial orbit into the optimum orbit for maximum transmission time, and thereafter to correct any deviations which may occur—thus maximizing the effective transmission lifetime of each satellite of the series.

Parliament in Britain

Britain's Space Programme

THE Prime Minister seems to be unmoved by a new request from Mr Neil Marten that more effort and resources should be put into space activities. Mr Wilson said that he does not believe that spending large amounts of money on prestige space projects is the most efficient way of using Britain's technological resources. Mr Marten thought, however, that it is high time that Britain moved towards getting its own capability for launching satellites for commercial purposes, instead of relying on the United States. (Oral answers, March 12.)

University Files

THE Privy Council cannot prevent universities from keeping files containing information on the politilac activities of students and staff. Its powers are restricted to approving amendments to university charters and statutes, and it has no jurisdiction over the internal administration of individual universities. This information was given by Mr Fred Peart, Lord President of the Council, in reply to a question from Mr J. P. W. Mallalieu, but Mr Peart also said that he believes that the practice of keeping such files should be condemned. The political opinions of staff and students are no business of a university, he said.

Mr Short, Secretary of State for Education and Science, said later that he also is powerless to prevent universities from keeping such files. Mr Short said that this is the responsibility of the university authorities, and he has no power to intervene in their internal affairs. (Oral answers, March 11 and written answers, March 12.)

Herbicide 2,4,5-T

ALTHOUGH the US government has banned the civilian use of the herbicide 2,4,5-T, and limited its use in Vietnam to unpopulated areas, it is not necessary to ban it in this country. This statement was made by Lord Delacourt-Smith, Minister of State, Ministry of Technology. The decision of the US government was based on toxicological tests which indicated that a toxic impurity in the herbicide may cause foetal abnormalities, but the British-manufactured variety is free from this particular impurity, said Lord Delacourt-Smith.

A voluntary safety scheme is operated with the assistance of a committee which gives guidance on the use of pesticides and herbicides, and Lord Delacourt-Smith said that, provided 2,4,5-T is used in accordance with the instructions laid down by the safety scheme, no danger and no hazard should arise.

Lord Brockway, for one, was not convinced. He suggested that many scientists are doubtful whether even the clean process used in Britain eliminates all the toxic impurity, because it may be regenerated by heat and light. He also accused the government of hushing up an accident in one of the factories manufacturing the herbicide, in which some people were poisoned. But Lord Delacourt-Smith said that the accident occurred because of overheating of the reaction mixture, and in such conditions the toxic impurity would be expected to form. He did not say whether anybody was injured by the accident. (Oral answers, Lords, March 11.)

NEW WORLD

Bleak Record of International Collaboration

ONE of the chief advocates of closer international collaboration in space research, Dr Thomas Paine, the director of NASA, had a sad tale to tell the Senate Committee on Aeronautical and Space Sciences last week about his agency's efforts to collaborate with others elsewhere. The most sombre part of his tale was the record of attempts at collaboration with the Soviet Union. He said that first attempts to cooperate in planning go back to the preparations for the International Geophysical Year in 1955, but that even then "agreements for exchange were held to a minimal or token level. The Soviet side has not fully complied even with these". Efforts at cooperation by the United States in 1959 are said to have come to nothing, and Dr Paine says that he considers "disappointing" the outcome of the agreement between the Soviet Union and the United States of June 1962 which allowed for the coordinated launching of experimental weather satellites and the exchange of such data as might result, the coordinated launching of Earth satellites equipped with absolute magnetometers and the use of communications satellites for joint experiments. This agreement was followed by one in November 1965 which would have produced a collaborative review of "space biology and medicine". Dr Paine explained that although the communications channels between Washington and Moscow intended for the exchange of meteorological data were established in October 1964, Russian transmissions of satellites as distinct from conventional weather data had not been "operationally useful". In the same spirit, he said that the Soviet Union has not yet said which of the data from the second of the orbiting geophysical observatories it wishes to receive, and that the exchange so far had been restricted to ground based data in an irregular fashion. The experiments with communications satellites may not be a good test of good will, for they were intended to be built around the Echo II satellite, but Dr Paine said that the Russians did provide reasonable data about radio reception even though they declined to transmit; a part of the difficulty with this experiment seems to have been at Jodrell Bank. The plan to produce a joint review of space biology, on the other hand, seems to have been frustrated by difficulties with correspondence.

Dr Paine gave a detailed account of the attempts that have been made to extend the collaboration between the United States and the Soviet Union in space research (see panel). In the past six months, according to this list, several invitations by NASA to the Soviet Union to collaborate in American space ventures have been rebuffed or ignored, although on December 12, 1969, Academician Keldysh, the president of the Academy of Sciences of the USSR, agreed that there should be a meeting "in three or four months" to discuss the further development of collaboration between the two countries while at the same time declining an invitation to mount Russian experiments in American interplanetary rockets.

Another thorn in Dr Paine's flesh seems to be the reluctance of the Russian authorities to provide more than "generalized assurances" that Russian rockets to other planets or to the Moon are in fact sterilized so as to prevent contamination. But Dr Paine seems to be a realist about this and accepts that collaboration with the Soviet Union "is not limited so much by technical considerations as by political considerations on the Soviet side", so that there is little prospect that the Russians will accept substantial proposals even though "we do not propose to stop trying".

Elsewhere, according to Dr Paine's account last week, collaboration has been more successful, even in comparatively humdrum fields such as the development of vertical and short range take-off aircraft, in which Canadian, French, German and British teams are involved. Dr Paine singled out the proposal for the German–American solar probe, towards which the West German government will contribute the greater share of the cost—more than $100 million altogether. There has been particular interest in collaboration on the space shuttle. According to Dr Paine, the principles of these agreements are that NASA should enter "only into concrete, carefully defined projects of clear mutual interest" and that the partners in the collaborative schemes should pay for their own responsibilities. Last October, 43 foreign governments as well as ELDO were given an outline of the plan for the space shuttle. Last week, ESRO, ELDO, the European Space Conference and a number of other governments were represented at a quarterly review of the development of the proposed space station. Similar meetings will follow later this year. Clearly, however, the degree to which these countries will participate, which Dr Paine says "depends on decisions that only they can make", is limited not merely by the novelty of the exercise but by the fact that countries other than the United States and the Soviet Union spend only about $300 million a year on space.

The difficulties are not merely financial. A spokesman for NASA said that the administration had been anxious not to lay down in advance the principles on which collaboration in new ventures should be based, but considered it was for "third" countries to make proposals themselves. The governments concerned are however at a loss to know how the kinds of contribution they might be able to make could win anything but a nominal part in ventures such as the space shuttle. As things are, where bilateral agreement to cooperate involves an American launching of, say, a French satellite, the French will pay for and build the satellite and NASA will provide the rocket on the understanding that information is equally shared. Where some practical use for the satellite is foreseen, as with the launching of telecommunications satellites for Intelsat, the manager of Intelsat (Comsat) will reckon to pay not merely for the satellite (which it contracts for directly) but for the direct cost of launching and something towards research and development.

Chronology of Collaboration

December 7, 1959. US offer of help in tracking Russian manned flights—Russians reply that they would ask for help "if the need arose".

March 7, 1962. Exchange of tracking and data acquisition stations declined.

September 20, 1962. No response to Kennedy's offer in the UN General Assembly for joint exploration of the Moon.

December 8, 1964. Proposed exchange visits to deep space tracking stations declined on the grounds that such visits were impossible.

May 3, 1965. No response to NASA suggestion of telecommunications experiments with Molniya I.

August 25, 1965. Invitation to launching of Gemini VI declined.

November 16, 1965. Further enquiry about the use of Molniya-1 declined by the Soviet Union as being impossible "in the present conditions".

January 6, 1966. Academician Blagonravov declined request for information about Russian experiments on Venus probe "to emphasize experiments which could complement rather than duplicate Soviet work" on the grounds that he had no authority to give the information.

November 11, 1966. Invitation to the launching of Gemini XII declined.

March 27, 1967. American request for advance information of soil analysis from Luna 13 met only after formal publication.

March 27, 1967. Proposals for small meetings between the Russian and American academies on weather prediction, planetary research and orbiting telescopes so far ignored.

June 2, 1967. Proposal for London meeting on exchange of weather data, specified under the agreement of 1962, denied—"the required semi-annual meetings have not been held since October 1965".

December 19, 1967. Proposal by Dr F. Seitz, then president of the US National Academy of Sciences, for a joint working party on Venus experiments accepted in principle on January 24, 1968, but "there has been no further Soviet response".

May 29, 1969. Invitation to Apollo 11 declined.

August 21, 1969. Invitation to planning meeting of Viking rockets to Mars declined on the grounds of lack of time (from September 3–11).

September 18, 1969. Proposal for exchange of biomedical scientists pending for further consultation in the Soviet Union.

October 3, 1969. Offer of lunar samples not taken up.

October 10, 1969. Academician Keldysh declined invitation of proposals for Soviet experiments on NASA space rockets but said that NASA and the Soviet academy should "coordinate planetary goals and exchange results of unmanned planetary investigations".

December 18, 1969. No response to invitation to Houston lunar conference.

January 29, 1970. Invitation to discussion of United States earth resources satellites declined.

INTELSAT

Agreement Snatched Away

from our Special Correspondent

Sometimes international conferences end not with a whimper but with a bang. This final week of the conference to decide on a permanent structure for Intelsat, the worldwide satellite system, began with such ferocity that the members had to retreat into private session, taking with them all the glowing press cuttings of last weekend, which had them breaking their year-long deadlock and reaching accord.

The dog in the manger once again seems to have been Comsat, the American satellite corporation, which has run Intelsat very nicely, thank you, without undue interference from its other so-called partners in the international consortium, since 1964. Comsat had seemed to be losing ground. The United States State Department surrendered first of all Comsat's majority role in the consortium and then, last week, gave away Comsat's claim to hold the managership permanently. The State Department agreed to what is called "internationalizing the managership" and decided instead to allow Comsat to hold the job—where the real power is—for six more years only. When the conference broke up at the weekend, delegates believed that they had agreed to agree on a compromise engineered by those two powerful nations least concerned with *le défi américain*, Japan and Australia. But when the agreement emerged on Monday morning in new clothes, dressed up in treaty language, it did not look the same at all. The director general, the executive who was supposed to choose a new manager when Comsat's term ended, was in plain language, emasculated.

None among the 74 delegations was really happy; there was, early in the week, no telling how it would all end. The tiny nations were particularly downcast. They have not won very much at all from the various bits of horse trading. And what they wanted was not so very much—to have their satellite ground stations counted as investment in Intelsat (instead of having their investment measured only by the amount of traffic that they sent through the system). What they also wanted, and may still be willing to fight for, was a kind of general assembly in which they had genuine power. As it looks now, the Intelsat assembly will have to be content with having one formal session, at which the main business will be to decide when they shall meet again.

Comsat will probably be manager for at least six more years, during which the next major round of contracts for a new generation of satellites will be handed out. But during that time Comsat will probably be supervised by a potent board of governors and an alert and non-American secretary general to look over its shoulder as it chooses satellite designs and dispenses Intelsat's money. The British–European bloc, while far from jubilant, is not miserable either. Its efforts and eloquence have been instrumental in demoting Comsat, something which seemed impossible two years ago. There is also general pleasure that the cumbersome conference which opened more than two years ago is crawling to a close. If the agreement that emerges is inelegant, it will nonetheless be both international and commercial and that is no small accomplishment.

OIL POLLUTION

Another Accident at Sea

The Chevron Oil Company is for the time being the most prominent member of the rogues' gallery of corporations offending against the environment because of its operation of an oil well in the Gulf of Mexico, a burning torch since February 10 which was converted into a source of about 50 barrels of oil a day when it was extinguished on Monday last week. No less a person than the Secretary of the Interior, Mr Walter J. Huckel, has gone to see for himself what damage is being done, especially at the bird sanctuary on Breton Island. Everybody—even the oil company—seems to agree that the offending well was not being operated in accordance with the more explicit regulations for offshore oil wells which were promulgated by the Geological Survey last August, after the escape of oil from an incomplete well off Santa Barbara, California.

The groups of a dozen wells now leaking oil lie about 20 miles east of the mouth of the Mississippi. Since the fire began, the Department of the Interior has suspended operations in the concession of 51 acres which Chevron has been opening up since it first leased it in 1958. Before the fire was extinguished with dynamite, it seemed as if the oil spill that would inevitably follow would be one of the most carefully controlled in the modern history of oil pollution. In the event, however, winds of ten knots in the gulf seem to have broken up the raft of booms constructed between the wild well and Breton Island, with the result that a large slick of oil began moving towards the coast. It is estimated that some two weeks will go by before the wild well can be sealed off from a hole now being drilled in at a slant.

Mr Russell Wayland of the United States Geological Survey explained last week that the new regulations require that oil wells should ordinarily be provided with devices known as storm chokes which are meant automatically to cut off the upward flow of oil in wild wells. The new regulations for offshore oil wells require that all wells should be provided with storm chokes, but the Geological Survey can waive this rule if the pressure in the pipe is too great for the chokes to operate successfully, or if the amount of sand being carried up with the oil is so great that the chokes would be worn out quickly. Although some of the wells in the Chevron field had been granted these waivers, the well which eventually caught fire, and which was unprotected, was not one of these.

In the circumstances, it is understandable that the oil company should have made valiant efforts to prevent the unavoidable oil slick causing damage to the coastline. Mr Wayland says that his department has been giving the oil company a rough time, and that all the offshore operators have been hurrying to comply with the new regulations. One problem, Mr Wayland said, is that of enforcing the regulations which exist—his small field staff cannot be present at all offshore drilling operations to ensure that they are complied with. It remains to be seen how severe will be the penalties which are visited on the Chevron Oil Company by the Department of the Interior. As well as permitting the closing of the oil field for an indefinite period, the regulations also allow the government to recover the money which it will have lost through the escape of oil—not a vast fortune—and to prosecute the offending companies in the courts, when success will bring fines of up to $2,000 a day for each violation and up to six months in prison for the violator—possibly the president of the company, possibly the operator of the rig, nobody is quite sure. The ultimate sanction is that flagrant violation of the rules may result in the cancellation of the lease to exploit a tract of offshore oilfield, but this would be accounted a thoroughly radical move by the Department of the Interior.

The delta of the Mississippi, like many other such tracts of land and water, is much frequented by wild fowl. Altogether there are close on a dozen bird refuges, the largest of which runs to close on a hundred square miles and which is maintained by the State of Louisiana, ironically with revenue derived from oil wells on the delta. Mr James Trefethen of the Wildlife Management Institute says that the species most at risk is the red-headed duck, which is at once rare and in the habit of venturing farther out to sea than other waterfowl wintering in the region, the canvas back duck and the pintail, for example. Mr Trefothen also says that if oil does eventually reach these areas, the waterfowl may nevertheless escape serious damage because the migration to the north is about to begin. There is even talk of using aircraft to speed the birds on their way to the north, which is another way of fighting fire with fire.

NUCLEAR POWER

Slow Pace of Reactor Development

The tightened budget of the Atomic Energy Commission means that the chief innovations in the coming year are likely to consist simply of the design of a 1,000 MW fast reactor using sodium as a cooling material. This much was clear last week. Mr Milton Shaw, director of Reactor Development and Technology at the Atomic Energy Commission, asked for a modest $194·6 million—substantially less than the $223·5 million that he asked for a year ago and $8 million less than his division was actually awarded for the current fiscal year. Spurred on not merely by logic but by the example of European nations, the AEC now says that the liquid metal fast breeder reactor is the cornerstone of its forward programme. What has happened so far is that three contractors are negotiating contracts for a design study, which should be completed in a year or so, when it will be possible to push ahead with the building of a 1,000 MW demonstration plant, probably starting towards the end of 1971. Although the AEC would like to build more than one plant of this kind, it has no authority to do so. So that the sodium fast breeder reactor can go ahead quickly within the confines of the tight budget, other promising candidates such as the molten salt breeder reactor, on which Oak Ridge has set its heart and which operates with thorium rather than uranium, have been put somewhat to one side.

The experimental basis of the sodium breeder reactor has now, according to Dr Shaw, been strengthened partly by the reorganization of the Argonne National Laboratory—a point urged on the AEC by the Joint Committee on Atomic Energy, the commission's most friendly critic—the commissioning of the experimental reactor EBR II (which is operating 25 per cent above its design power at 62·5 MW) and also by the resuscitation of the Enrico Fermi reactor, which has been out of commission since the accident there in 1966 but which is now being reloaded with fuel. The AEC estimates that the cost of the liquid metal breeder reactor programme will increase from just over $100 million a year in the current fiscal year to a maximum of $175 million in 1972 and 1973, by which time the contribution of the construction companies to the cost of building reactors will be $100 million a year or thereabouts. (Mr Shaw estimated last week that industrial companies are already providing $25 million a year towards the cost of a broadly based programme of research and development.) The alternative designs being considered are based either on combinations of uranium oxide and plutonium oxide (General Electric and Babcock and Wilcox) or combinations of the carbides (Westinghouse). In testing programmes already carried out, mixed oxide fuels have been carried to more than 11 per cent burn-up, and the mixed carbide fuels are not far behind.

Like the molten salt reactor, the high temperature gas reactor will also trudge along at a comparatively modest level in the coming year—each project will get $5 million under the proposed budget. Even so, the Peach Bottom reactor is now operating successfully, another high temperature demonstration plant should be critical in just over a year from now and Mr Shaw estimates that the first commercially viable plant should come into operation in 1977 or 1978, in time for this reactor type to make a contribution to the fuel economy of nuclear power stations by the eighties.

The concentration of interest in the liquid metal fast breeder reactor reflects the anxiety in the AEC to ensure the arrival of a second generation of nuclear reactors, chiefly so as to avoid the difficulty there will otherwise be with the supply of natural and enriched uranium. One calculation, described by Mr Shaw last week, is that if the fast breeder reactor can be introduced by 1984 into commercial service, it will be possible to live within a total uranium commitment of just under a million short tons of uranium oxide (chemical formula U_3O_8), the amount of uranium ore which can be won for $10 a pound or less. By the same test, if the introduction of the fast breeder reactor has to be postponed until 1994, it will be necessary to break into uranium reserves which cost up to $15 a pound. The result will be permanently to increase the cost of uranium fuel.

This year's hearings before the Joint Committee on Atomic Energy are being held in circumstances a good deal more cheerful for the commercial operators than in 1969. Although there has now been a recovery, with something like 12,000 MW of capacity ordered in the past twelve months, the rush by the utility companies into nuclear power has not yet matched again the happy days of early 1967, when 9,000 MW were ordered in the second quarter, making a total of more than 25,000 MW for 1967 as a whole. A part of the difficulty is that the nuclear construction industry has tended frequently to fall behind its promised construction dates. Another is that public opposition to the construction of power stations, nuclear or conventional, has made it hard for utilities to push ahead as quickly as they would like with new plans. The classic example, no doubt, is the proposed pumped storage scheme at Cornwall, New York, which has been held up for eight years by local objections, most of them on the grounds of amenity. Even so, it now looks as if additional nuclear generating capacity will be commissioned at a rate which averages or even exceeds 10,000 MW a year from 1971 on.

The relationship between nuclear power stations and their immediate environment has been for the past few weeks, as it was last year in October and November, a particular concern of the Joint Committee on Atomic Energy. Last year, the committee did much to uncover some of the anomalies in the regulations for the siting of nuclear plants—it turns out, for example, that the

SPACE

Vote of Affection

The House of Representatives Committee on Science and Astronautics has made its customary declaration of faith in and affection for the National Aeronautics and Space Administration by voting that the Administration's request for a budget of $3,333 million for the coming year should be increased to $3,630 million. At this early stage of the budgetary process, it is unlikely that Dr Thomas Paine and his programme managers will be lulled into the belief that there will, after all, be an extra $297 million to spend. Not merely has the Senate committee yet to have its say, but there is now what seems to be a well established tradition that the appropriations committee takes away what the authorization committee—the Science and Astronautics Committee—adds to the Administration's budget request. In these circumstances, the vote on the budget in the authorization committee is more a guide to sentiment than a promissory note.

Briefly, it seems that members of the House committee have been convinced of the rightness of most of the innovations in the new space budget and, at the same time, regret the running down of programmes with which they have become familiar. Thus the extra sums of money voted include $145 million to prepare payloads for Apollo 18 and 19 and to make preparations for Apollo 20. The committee also suggests that $100 million should be spent on potential bottlenecks in the Saturn V programme. Similarly, the committee asks that an extra $75 million should be spent on the orbital workshop, not merely to extend the work that will be done on the three planned visits to the first of the orbiting stations, but also to begin work on the design of a second and better place to visit. The committee also asks that $80 million should be spent on the space shuttle.

In a much more modest spirit, the committee has also made known its feelings by asking for modest sums of money to be spent on research into the reduction of noise caused by aircraft and the avoidance of collisions in the air. The committee's generosity does not, however, extend to that part of the programme which used to be called the University Sustaining Program and which is now due to be wound up—that is an unpopular cause this year.

AEC is required to approve all new nuclear power stations so as to provide an assurance of safety from radiation hazards, but that it is for state power commissions to regulate other features of the enterprise and in particular to decide whether the arrangements for disposing of cooling water are satisfactory. Because states seem to vary considerably in their practice, it is no wonder that what is called thermal pollution has become an important issue. One welcome result, however, is that utility companies are increasingly providing either cooling towers or cooling ponds for preventing damage to life forms in rivers or the sea by the discharge of water that is too hot—nuclear plants are comparatively serious offenders in this respect because of their comparatively low efficiency for the conversion of mechanical into electrical energy—even though it is estimated that the extra capital costs of cooling ponds may range from between $2 and $3 a kilowatt for fossil fuel plants to between $3 and $4 a kilowatt for nuclear plants, and that cooling towers may add between $4 and $6 a kilowatt to the capital cost of a fossil fuel plant and between $6 and $8 a kilowatt for a nuclear plant. Something like a quarter of the power stations now being built have such cooling systems. There are many who will say that it is not before time, given the estimate by the Water Resources Council that, by the end of the century, power stations of all kinds using rudimentary cooling systems would use five hundred thousand million gallons of water a day, more than 40 per cent of the average run-off from the surface of the United States.

SEISMOLOGY

Let More Sun Shine

SEISMOLOGY is the latest branch of science to be patted on the back by the committees of the National Academy of Sciences which are surveying the opportunities for new research and identifying the points at which money needs most urgently to be spent. The committee which has now argued that more seismology would be a good thing (*Seismology: Responsibilities and Requirements of a Growing Science, Parts I and II*, NAS, $5.50) has had as chairman Dr J. E. Oliver of the Lamont-Doherty Geological Observatory of Columbia University. A good deal of its thunder has been stolen by the National Science Foundation, which used many of the same arguments in presenting its case for a programme of earthquake engineering to Congress three weeks ago. Inevitably, however, the way in which attention has been concentrated on one of many geophysical techniques makes the committee seem guilty of special pleading, however valid its case may be. Indeed, the appearance of this latest report may draw attention yet again to the need to put together the several assessments of research opportunities in particular fields in one balanced assessment of science as a whole. This, by all accounts, is a project on which the National Academy of Sciences has now embarked by recruiting close on 80 distinguished potential members for the interlocking set of committees to produce the review which subsumes all lesser reviews.

The committee on seismology says that the rapid growth of seismology in the United States in the past two decades has been stimulated partly by the preoccupation with underground test detection under Project Vela-Uniform and partly by collaborative schemes such as the IGY and the Upper Mantle Project. Understandably, the committee is afraid that the "reorientation" of the Vela-Uniform work and the ending of schemes such as the Upper Mantle Project may decrease the support available for worthwhile projects in seismology. Especially because of the pace at which understanding of the Earth is deepening, the committee considers that the present time is one when a fresh assessment is urgently called for.

Given the value of seismology in test detection, the committee asks that there should be new federally sponsored programmes "so that seismologists can apply their special capabilities to an attack on other pressing national problems". In particular, the committee asks that there should be research related to the hazards of earthquakes and even to their prediction and control as well as an investigation of the economic and scientific implications of the doctrines of sea floor spreading and continental drift "in cooperation with other earth scientists". The committee has the practical suggestion that the government should assume responsibility for a national centre for acquiring and distributing seismological information based on the World-Wide Network of Standardized Seismograph Stations. This is a need to which others have previously drawn attention (see *Nature*, **225**, 844; 1970), and indeed there are fears that the efficacy of the WWNSSS may be seriously impaired, now that it has just been completed, by lack of funds. The committee suggests that financial support for seismology should grow from $35 million to $50 million a year in the next few years, and few people will protest. The doubt will be whether there should be what the committee calls "a national program in seismology", presumably separate from a national programme in oceanography.

The Oliver committee says that "the present and future goals of seismology must be keyed to the overall goals of society in an age dedicated not only to the acquisition of scientific knowledge for its own sake but to the application of this knowledge for the benefit of mankind". It goes on to argue that a better knowledge of seismicity and more vigorous programmes of engineering seismology will make it possible to mitigate the effects of earthquakes. Although the committee acknowledges that forecasting the time and the size of an earthquake is still beyond the bounds of possibility, it considers that there may be some hope in investigations of accumulating strains, rock creep along faults, micro-earthquakes and general geophysical processes in the crust of the Earth. The committee also asks that somebody should study the question of how populations respond to the threat of earthquakes. Whether or not the prevention of earthquakes will ever be possible, the committee says that this must "rank as a major goal of seismology", and cites as evidence the artificial triggering of earthquakes in Denver by injecting fluid into the Earth as well as in Nevada by underground explosions (see also page 1099). In the budget of the National Science Foundation for 1971 is included $2 million for earthquake research—among the schemes on which the foundation will sponsor work is one for constructing an earthquake simulator consisting of a movable oscillating platform 20 feet square (see *Nature*, **225**, 785; 1970).

NEWS AND VIEWS

Dust-up in Nevada

It is rare for a scientific article to elicit ferocious response within weeks of publication—most experimental studies and theories are poised on a superstructure of unique apparatus or theoretical formalism not immediately accessible to the reader. The experience of Emiliani, Harrison and Swanson of the University of Miami is thus all the more singular. In *Science* (**165**, 1255; 1969) they postulated that underground nuclear test detonations in Nevada were causing increased earthquake activity at distances out to 860 km from the test site. They also suggested that such explosions might be useful in controlling earthquake activity.

Predictably they have received a sharp rap over the knuckles, and three rejoinders (*Science*, **167**, 1011; 1970) have been published signed by no fewer than nine luminaries of the seismological world. The whole seismological staff of the California Institute of Technology add their weighty names to one such letter. The experience is perhaps more of a psychological than a geophysical happening—it reflects things felt rather than things known, and it reveals the danger of attempting to copyright what is no more than coffee-room musing.

The question of destressing a region by some explosive process arose in 1963, when it was appreciated that some explosions have an earthquake type of radiation pattern. Recent large nuclear tests in Nevada have triggered near-in (less than 20 km away) earthquakes by the thousand, a phenomenon which is universally known but little understood. Do the earthquakes release pre-existing stress or only stress accumulations from the explosion itself? Nobody knows for sure and a coordinated programme of earthquake control, such as the United States hovers on the brink of supporting, must regard this as one of its priorities. Hence, probably, a certain amount of irritation that Emiliani *et al.* should claim originality for their suggestion of earthquake control. To their credit they have made a full retraction of their claim to be the first to suggest it.

The issue of increased seismicity is more thorny, and this is not the first time that feathers have flown. For the past fifty years people have hunted for periodicities in earthquakes as a step towards their prediction. Such claims for periodicities have tended to diminish with the advent of improved facilities for harmonic analysis, but some apparent periodicities remain with us and call for continued study. One prerequisite, insufficiently realized, is the need to find a scoring system so that events of different magnitudes are given appropriate weight. Straightforward counting is not enough, and may be highly dependent on the network of stations used.

Another decision that needs to be taken concerns aftershocks of large earthquakes. Do they score in the same way as main shocks? Is the frequency of aftershocks controlled only by the nature of the main shock, or could a large shock render an area particularly prone to any periodic forces such as Earth tides? These questions, posed many times in periodicity studies, apply with equal force to the arguments of Emiliani *et al.* Credit where credit is due, the authors respond to their critics by showing data called for and on the basis of this there is a statistically significant increase in activity out to 800 km in the first 32 hours after a test. But there is no indication of magnitude of event, size of relevant explosions nor an adequate analysis of the incidence of aftershocks. The implications of what Emiliani *et al.* have said are great, but very few would yet attach any label other than "not proven" to the idea. A more sophisticated approach than straight counting is needed.

PLANETARY NEBULAE

Doublets give Electron Density

by our Astronomy Correspondent

A method of determining electron densities in planetary nebulae by observing the ratios of certain line intensities has been described by H. E. Saraph and M. J. Seaton, and an account of the work was given by Professor Seaton at last week's meeting of the Royal Astronomical Society. The technique is to measure the intensities of the two lines in certain doublets, and it seems that although the intensity ratio is insensitive to temperature, the ratio is very sensitive to electron density. The case of the OII doublet—3726 Å and 3729 Å—has been studied for several years, but Saraph and Seaton have extended the electron density measurements to other doublets which have not been studied in detail before.

One advantage of their new set of doublets is that the separations are greater than for the OII lines so that spectrograph dispersions need not be so high as for the OII case. The larger separation also means that electron density measurements can sometimes be taken in galaxies where the OII doublet cannot be resolved because of Doppler broadening.

The doublets which Saraph and Seaton discuss are SII (6731 and 6717 Å), ClIII (5538 and 5518 Å), ArIV (4740 and 4711 Å), and KV (4163 and 4123 Å). With the exception of SII, the intensity ratio for each doublet seems to have a larger sensitivity to electron density than OII, for a wide range of densities at least, and in particular the sensitivities are greatest around the electron density values which are typical of many planetary nebulae.

Actual measurements reported by Saraph and Seaton show good agreement between electron densities obtained from different ions. Observations of IC 418, for example, give values of log n_e of 3·9, ≤4·4 and 4·1 from the SII, OII and ClIII doublets respectively. In objects of high excitation the situation seems to be different, and for NGC 7027 values of log n_e of 3·8, 3·7, 4·3, 5·3 and 5·1 are reported from the doublets SII, OII, ClIII, ArIV and KV respectively. The electron density seems to be larger at high excitation levels, and no unique electron density can be assigned to these objects.

ROCK MAGNETISM

Oxidation and Hysteresis

from our Geomagnetism Correspondent

THE correlation between the petrographically determined oxidation state and the polarity of natural remanent magnetization (NRM) in some igneous rocks remains a puzzle. If most reversely magnetized rocks are due to field reversal—and the evidence for field reversal is too strong to be denied—there should be no correlation between polarity and the nature of the magnetic minerals present. The strength of the NRM, on the other hand, depends on the properties of the magnetic material, some of which can be assessed petrographically. Clearly the intrinsic magnetic properties of a rock are an important link between the NRM and the optical properties, and much more needs to be known about the whole chain before oxidation-polarity correlations can be understood.

The problem in trying to correlate intrinsic magnetic properties with oxidation state is that many of the properties (the Curie point, for example) can only be determined by heating, which may alter the oxidation state. Moreover, room temperature properties, such as saturation magnetization, are difficult to interpret because it is impossible to obtain from the rocks highly refined extracts of the various magnetic minerals. But Day *et al.* (*J. Geophys. Res.*, **75**, 375; 1970) have successfully demonstrated that there is another indicative magnetic property, determination of which involves neither heating nor extraction. This is rotational hysteresis, the work done against irreversible magnetization processes when a sample of magnetic material is rotated through 360° in a magnetic field.

Day and his colleagues have measured the rotational hysteresis (*W*) as a function of magnetic field (*H*, up to 21,000 Oe) for natural rock samples and synthetic titanomagnetites, magnetite, maghaemite and haematite. The *W–H* curve from each rock was then examined in relation to the rock's oxidation state (classes 1 to 5, using the scheme of Wilson and Haggerty, *Endeavour*, **25**, 104; 1966) determined petrographically. This revealed that each oxidation class has its own characteristic *W–H* curve. All *W–H* curves possess a peak at low fields with a tail extending to the highest field available; but the width and position of the peak and the size of the tail vary with the oxidation state. By comparing the rock and synthetic sample curves, Day *et al.* were able to identify the operative magnetic minerals present in the rocks (see table).

MAGNETIC MINERALS FOUND IN ROCKS BY DAY *et al.*

Oxidation class	Magnetic mineral content
1*	Titanium-rich titanomagnetite
1†	Iron-rich titanomagnetite
2	Cation-deficient spinel phase
3	Iron-rich spinel phase
4	Magnetite and small amount of haematite
5	Haematite and small amount of magnetite

* Low Curie point.
† High Curie point.

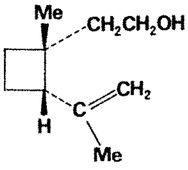
An obvious consequence of these results is that it should be possible, with a little care, to use rotational hysteresis to determine oxidation class without resort to laborious petrographic techniques. A more fundamental point to emerge, however, was that the most stable rocks fall into class 3. In other words, surprisingly, maximum stability is not associated with haematite which is known to be highly stable, and more stable than titanomagnetites. But the general point is that it is now possible to determine the magnetic mineral content of a rock without destroying it chemically or physically.

PHEROMONE SYNTHESES

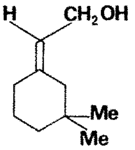
Trapping the Boll Weevil

from a Correspondent

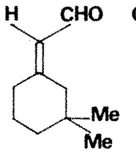
COTTON growers who read the *Journal of the American Chemical Society* will be cheered to learn that the pheromone of the pestilential boll weevil has been synthesized. Pheromones, the chemicals secreted in minute quantities by insects to influence the behaviour of other members of the same species, have great potential value in the chemical control of insect pests. The procedure would be to attract insects to traps containing insecticides by baiting the traps with pheromones.



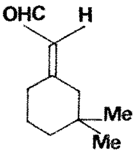
(I)



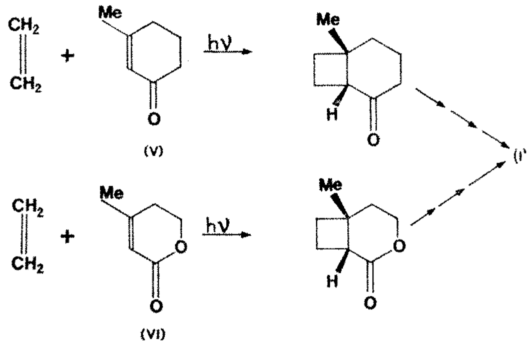
(II)



(III)



(IV)



The American cotton boll weevil does some $100 million damage annually to the US cotton crop. The male of the species secretes a pheromone which contains the four terpenes (I–IV) in faecal concentrations of 0·76, 0·57, 0·06 and 0·06 p.p.m. respectively. Stereospecific syntheses of the more complex alcohol (I) have been completed recently by research teams at the Zoecon Corporation in California and in the US Department of Agriculture's Boll Weevil Research Laboratory in Mississippi (R. Zurflüh, L. L. Dunham, J. L. Spain and J. B. Siddall, *J. Amer. Chem. Soc.*, **92**, 425; 1970). Both syntheses construct the four-membered ring by the photochemical addition of ethylene to a cyclic olefin; the former group choosing 3-methylcyclohexenone (V) and the latter group using a dehydration product of mevalonolactone, 3-methylpent-2-enolactone (VI). This photoaddition guarantees the correct *cis*-stereochemistry for the ultimate product (I) which is obtained in 10 per cent overall yield after further chemical transformations to give the correct side chains.

Without this component, mixtures of the other three synthetic compounds fail to attract boll weevils whereas the attracting power of the combination of all four chemicals in the correct proportions closely matches that of the natural pheromone. This research may not only provide a solution to the control of the boll weevil, but also assist in restricted distribution of insecticides.

AMPHIBIA

Ancestors of the Reptiles

from our Vertebrate Palaeontology Correspondent

The vexed question of the amphibian ancestry of the reptiles has been aired again. According to R. L. Carroll, the carboniferous tetrapod, *Gephyrostegus*, although too recent to be the ancestor in question, seems to have the characteristics required for such an evolutionary position (*Phil. Trans. Roy. Soc.*, B, **257**, 267; 1970).

The most important criterion distinguishing living reptiles from amphibians is their mode of development. Reptiles (and birds) usually lay an egg which provides all the material needs of the developing embryo so that it may hatch fully formed. This amniote egg has not developed in amphibia and a protracted larval stage is common, although many species have curtailed or even eliminated this vulnerable stage in their development by other means. When dealing with the fossil remains of early tetrapods it is thus very difficult to establish criteria for deciding whether a given "reptiliomorph" tetrapod is to be classified as a reptile or an amphibian.

Many years ago, the fossil tetrapods, thought to be the most primitive reptiles, were placed in three groups by D. M. S. Watson: the first represented by *Seymouria*, the second by *Diadectes* and the third by *Captorhinus*. All three "type" genera were from early Permian deposits from Texas and surrounding states. For many years the status of *Seymouria* was disputed: was it a reptile or an amphibian? On the one hand, it was a sturdy terrestrial form with many characters regarded as reptilian; and on the other hand, the structure of the middle ear region, critical to the interpretation of early tetrapods, favoured amphibian affinity. The matter was finally settled when Špinar in Prague demonstrated that closely related forms from the European Lower Permian developed external gills during their development and thus had a larval stage.

Thus *Seymouria* was an amphibian, but it was still accorded an honoured place as a relict reptilian ancestor. It was recognized, however, that while it was probably closely related to *Diadectes*, a massive form with an enormous otic notch to hold the eardrum, it was not particularly closely related to *Captorhinus* and its allies, small lizard-like forms with no otic notch, and with an eardrum that must have been situated behind the skull. Unfortunately for the status of *Seymouria* it is *Captorhinus*, or rather its less specialized predecessors, which are probably the most closely related to the ancestry of all subsequent reptiles.

These primitive captorhinomorphs occur very much earlier in the fossil record than either *Captorhinus* or *Seymouria*. The earliest known comes from a horizon in Nova Scotia which is early Pennsylvanian and probably equivalent to the Middle Coal Measures of Britain. This and another somewhat later and better preserved form (*Paleothyris*) have been described by Carroll, of the Redpath Museum, McGill University, as part of a general attack on the problem of reptile origins. He has also undertaken a detailed anatomical study of several little known and difficult fossils from Carboniferous horizons in Europe more recent than the British Coal Measures. Most important of these is the genus from Nýřany in Bohemia, but there are other specimens of disputed affinity which he considers the descendants of early offshoots of the amphibian–reptilian evolutionary stock.

Last year (*Biol. Rev.*, **44**, 393; 1969) Carroll characterized *Gephyrostegus* as an ideal relict of the reptilian ancestor, although, like *Seymouria*, too late in time to occupy a true ancestral position. However, it lacks some of the aberrant specializations of the ear region which *Seymouria* has. Carroll attempted to demonstrate by a close comparison of the whole skeletons of *Gephyrostegus* and *Paleothyris* the stages in the evolution of a reptilian skeleton from an amphibian skeleton.

His latest contribution has been to describe the anatomy of *Gephyrostegus* and other forms from Nýřany as well as an allied form from a roughly contemporary horizon in the United States. This work is likely to establish *Gephyrostegus* as demonstrating the anatomy of the reptile ancestor, but a lingering doubt remains. While *Gephyrostegus* lacks the specializations of *Seymouria* its skull is still basically similar and in critical features of the back of the skull roof and occiput thus resembles *Diadectes* rather than the certainly reptilian captorhinomorphs. Meanwhile, *Diadectes* has come to be considered by many as a sterile end form of an evolutionary line quite separate from true reptiles.

EVOLUTION

Ammonites indicate Reversal

from a Correspondent

Can the course of evolution turn back on itself? Or does some sort of momentum keep an organism proceeding in a particular evolutionary direction, even if this results in the production of aberrant and non-adaptive types, forming an evolutionary cul-de-sac ending in extinction? Among evidence often cited for the latter point of view is the production of aberrant forms by the familiar spiral-shelled ammonites, of which fossil remains are found from the early Devonian through to the Cretaceous. In these aberrant forms, called heteromorphs, either the whole shell, or part of it, is unrolled. This is interpreted as a sign of overspecialization or racial senility, preceding inevitable extinction.

A drawback of this point of view is that it effectively credits evolution with an intrinsic rhythm, comparable with that of an individual life, with each type having a youthful phase of explosive development, then a long period of advancing specialization, and a final phase of senile overspecialization and morphological degeneration. This is, of course, in direct contradiction to Darwin's selection theory, which cannot explain the appearance of any organisms which are selectively negative. On the other hand, it does tally with the "law" of the irreversibility of evolution which Dollo put forward in 1893.

The use of uncoiling ammonoids to support the idea of an endogenous rhythm in evolution has now been challenged by Jost Wiedmann, of Tübingen University (*Biological Reviews*, **44**, 563; 1969), after careful study of the heteromorph ammonoids of the Triassic, Cretaceous and Jurassic eras. In particular, he looked to see, first, whether these heteromorphs really appeared explosively at the end of evolutionary lines; second, if their development was irreversible; and third, whether they really were short lived, degenerate or overspecialized, and had lost the ability to adapt or change, thus being "condemned" to extinction.

He found that the Triassic heteromorphs were a single monophyletic group, with a long stratigraphical range through the whole of the later Triassic, suggesting that here the uncoiling was an adaptive change, possibly related to living on the sea bed, and with no indication that it was due to an unselected and somehow internally elicited mutation. The Jurassic heteromorphs, too, seem to have been a monophyletic group persisting for a long time, and some of these do show signs of re-coiling, as do several groups of Cretaceous heteromorphs. Indeed, here some of the uncoiled forms turned out to be older than their coiled supposed ancestors, and so their phylogenetic development must now be read in the opposite direction—that is, from uncoiled to re-coiled.

Wiedmann thus finds no evidence to support the assertion that "a re-coiling of forms which have become secondarily rod-like does not occur". In fact, if one regards the ammonites coiling early in their evolution in the Devonian era as being primary, the re-coiling of the heteromorphs he has found here is actually tertiary, with some of the re-coiled forms even showing a later quaternary uncoiling. This means, of course, that the final extinction of the ammonites at the end of the Cretaceous needs some explanation other than endogenous racial senility. Wiedmann points out that many other marine groups died out at the same time, so that changes in sea level provide a more satisfactory answer than either an immanent evolutionary ageing, or factors like cosmic rays or supernovae. Second, it clearly calls for a reconsideration of what he calls the "most undisputed of the phylogenetic laws", namely Dollo's "law of irreversibility". This was originally stated as "an organism is unable to return, even partially, to a previous stage already realized in the ranks of its ancestors" and the too strict application of this rule has already been challenged, especially by geneticists, who have pointed out that reverse mutations should not be ruled out *a priori*. Now Wiedmann concludes that in palaeontology the over-hasty formulation of such phylogenetic "laws" and "principles", based on insufficient information, has produced "a stifling set of prejudices" rather than "guide lines crystallized from long experience and observation". This all serves to stress very neatly the often overlooked point that in science, the so-called "laws" are, in Karl Pearson's phrase, "descriptive and not prescriptive", so that where facts clash with the law, and the exception proves (that is, tests) the rule, the facts should aways prevail.

SPECTROSCOPY

ESR for Biologists

from a Correspondent

RESEARCHERS in the biological sciences are showing increasing enthusiasm to add electron spin resonance (ESR) to their range of spectroscopic techniques. This became evident at a symposium on ESR in biological systems held at Liverpool Polytechnic on March 11 and 12.

Although the applicability of ESR to biological systems is somewhat limited by the scarcity of paramagnetic centres in biological molecules, this has the advantage of making ESR a very specific method for probing a particular part of those molecules containing a paramagnetic species. Dr J. C. Swann (Chester Beatty Research Institute, London) illustrated this when describing how the mechanism of action of the enzyme xanthine oxidase has been largely elucidated by ESR studies of the molybdenum and iron atoms and an FAD radical in its active site. The molybdenum atom has proved the most useful probe, and experiments with deuterated substrates and in ^2H_2O solution have shown that the mechanism involves direct hydrogen transfer from the reducing substrate to a position near the molybdenum atom where it is exchangeable with the solvent. The oxygen radical (O_2^-) has been detected as an intermediate in the reduction of molecular oxygen by the reduced enzyme, using ESR in conjunction with the rapid-freezing technique developed by Bray. The identity of this radical has been confirmed in experiments with oxygen-17.

The utility of the isotope substitution method was also demonstrated by Dr J. F. Gibson (Imperial College, London), who talked about the ESR of iron–sulphur proteins, which include ferredoxins, oxidative enzymes of mitochondria and xanthine oxidase. They are characterized by an iron signal with unusually low average g value (less than 2) and anomalous temperature sensitivity. The temperature sensitivity has been simulated in an inorganic iron–sulphur system, but there are no inorganic analogues with such low g values. Isotope substitution using either iron-5 or, in place of sulphur, selenium-77, reveals that each iron interacts with the other and with two selenium nuclei. Thus the characteristic signal seems to come from a two iron–two sulphur entity.

The more familiar iron compounds of biological interest are the haem iron proteins, and Dr E. F. Slade (University of Keele) discussed determinations of zero field splitting tensors in myoglobin using 2 and 4 millimetre wave ESR instruments with superconducting, liquid helium temperature magnets. A transition between the lower two Kramers doublets is not seen, presumably because of depopulation of the upper level of the ground state doublet at liquid helium temperature, but estimates of the splitting have been obtained indirectly. Results for haemin chloride agree with direct spectroscopic determination, but other results have not confirmed estimates from Mössbauer spectroscopy.

Many molecules of biological interest which have no paramagnetic centre can be modified by attaching a small synthetic probe containing a stable nitroxide radical. This spin labelling technique developed by McConnell was described by Dr D. Chapman (University of Sheffield). The method is based on the anisotropy of signals from the nitroxide radical which thus acts as a "reporter" of molecular motions (for example, whether the spin label is in a region of free or restricted movement). Applications have ranged from studying conformation changes in proteins to obtaining evidence for the bilayer structure of phospholipid membranes. Interaction of lipid membranes with drugs and anaesthetics has also proved tractable to the spin labelling approach. Chapman emphasized, however, that possible perturbation of the biomolecular structure by the spin label must be considered, and that the method should be considered as complementing rather than outmoding more classical techniques, such as polarization of fluorescence.

NERVOUS SYSTEM

Central Cholinergic Mechanisms

from a Correspondent

Much has been heard about the significance of central neurones, with monoamines as transmitters, for an understanding of neurological and psychiatric disorders and the action of centrally acting drugs. But cholinergic neurones, using acetylcholine as their transmitter, are no less important, being involved, for example, in ascending systems of neurones which may have an important role in attention, awareness and consciousness. Investigations, however, have been held up for lack of a sufficiently sensitive and specific chemical method for estimating acetylcholine. But at the international symposium on the effects of drugs on cholinergic mechanisms in the central nervous system, held at Skokloster, Sweden, from February 23 to 25, Dr D. J. Jenden (Los Angeles) thought that it should soon be possible to estimate picomolar quantities in tissue samples and fluids using a combination of gas chromatography and mass spectrometry.

Much of the meeting was taken up with an examination of the storage and release of acetylcholine and how they are affected by drugs, using superfused cortex, cortical slices and isolated nerve terminal synaptosomes. The synaptosome has turned out to be a most versatile organelle. Dr H. F. Bradford (London) explained how to make "reconstituted slices" from synaptosomes which have most of the metabolic properties of brain slices, including a large increase in oxygen uptake when electrically stimulated. He also showed that of the six or so uncombined amino-acids present in synaptosomes in considerable amounts, only those known to have transmitter-like effects on central neurones are released on stimulation. Dr M. P. Blaustein (St Louis) observed that in metabolizing synaptosomes the uptake of calcium ions is stimulated by potassium ions in a manner very similar to that of intact neurones. He considers that the metabolizing synaptosome has a normal resting membrane potential.

When the topic was the cholinergic receptor and its structural and functional relationship to acetylcholinesterase, Dr E. Heilbronn (Sundbyberg and Uppsala) described the morphological changes in brain slices which result from treatment with phospholipases. The pre-synaptic portions of the terminal membranes are selectively destroyed, leaving clumps of intact vesicle and synaptic clefts; such preparations should be a valuable new starting material for the isolation of the post-synaptic membrane, particularly if allied with the new high resolution separation techniques using zonal rotors described by Dr R. H. Mahler (Bloomington) and Dr V. P. Whittaker (Cambridge and Staten Island).

VIROLOGY

Where to get Monkey Viruses

Many virologists still do not seem to be aware of the services available to them at the simian virus reference centre of the Southwest Foundation for Research and Education in San Antonio, Texas. Dr S. Kalter, director of the foundation's division of microbiology and infectious diseases, writes: The increased use of non-human primates in biomedical research prompted the need to develop a centre to which researchers could turn with their virological problems. As a result, a simian virus reference centre was set up in 1966 at the Southwest Foundation, with support from the World Health Organization; in 1968 the US National Institutes of Health added its support. The centre is called the Collaborating Laboratory on Comparative Medicine: Simian Viruses (*WHO Chronicle*, **23**, 112; 1969).

The centre aims to develop a working repository for simian viruses, and to provide a source of reagents such as strains of certified reference seed virus and specific antisera. At present there are reagents available for all accepted prototype simian viruses. We try to obtain new simian viruses as they are described, in order to prepare stocks and develop suitable antisera.

Consultation services are available to deal with questions about the existence of antibody to viruses of human and simian origin in various primates. There are also diagnostic services, including facilities for the identification and characterization of viruses for primatologists who are unable to identify their own isolates (this includes screening for human viruses). An information service is also available, and exchanges of organisms between primate centres and other health organizations can be arranged. The Texas centre also has facilities for the training of students in the procedures of primate virology. The address of the centre is: Division of Microbiology and Infectious Diseases, Southwest Foundation for Research and Education, PO Box 28147, San Antonio, Texas 78228.

VIRUS INFECTION

Good News on Poly-I : C

from a Correspondent

During the past two to three years the synthetic double stranded RNA, polyriboinosinic acid–polyribocytidylic acid (poly-I : C), which induces interferon, has been shown to have a significant antiviral effect in animals and tissue culture. In spite of previous indications of unpleasant side effects in animals, recent clinical trials have had hopeful results. Some good news was delivered by Dr S. Baron (National Institute of Allergy and Infectious Diseases, Bethesda) and his colleagues at the international symposium on medical and applied virology in Fort Lauderdale on December 14–17, and at the Gustav Stern symposium on perspectives in virology at New York on February 2–3.

Baron *et al.* first examined the effect of poly-I : C on experimental rhinovirus infection in humans. When the dose estimated to confer protection, and still be safe, was given to volunteers, working up from one tenth of the dose, no evidence of toxicity was found. The subjects for trials against experimental virus infection were eighteen healthy volunteer prisoners, selected for a low concentration of serum neutralizing antibody to rhinovirus-13, so that they should be susceptible to infection. On the day before virus challenge, eight men were given 0·1 mg/kg body weight of poly-I : C intranasally; the rest received placebos. Further doses of poly-I : C or placebo were given for 5 days after infection, and the men were examined independently for symptoms. Five out of ten of those given placebos developed colds, compared with one in eight of those who received poly-I : C. And fewer viruses were recovered from the nasal washings of treated men. Probably more significant than the development of colds was the overall reduction in symptoms in the treated group, as measured by symptom score analysis.

When influenza virus was the challenge there was again a reduction in disease and symptoms—illness occurred in four out of nine subjects treated with poly-I : C and in seven out of ten given placebos.

Baron *et al.* also investigated the relationship between interferon titre and doses of poly-I : C in patients with either encephalitis or cancer, to look for ways of preserving a high titre of interferon for the longer periods necessary in prophylactic treatment. After one dose of poly-I : C there was a decrease in interferon after 24 hours, reaching a minimum after about 3 days. Further doses given during this period of decline had no effect. But in some cancer patients, treated intravenously, a dose given 7 days after the initial dose induced some interferon. Intravenous injections caused fever, reversible suppression of erythrocyte formation, and in one patient an allergic reaction.

These results are all encouraging, although only a few subjects were involved, both for the protection afforded by poly-I : C and for the apparent lack of side effects from intranasal treatment. On the question of toxicity, it should be remembered that experimental virus challenge doses are usually much higher than those occurring in natural infection, and so much less interferon inducer should be necessary for prophylaxis, with a reduction in possible toxicity. Certainly this is an interesting beginning to the therapeutic use of a synthetic interferon inducer in humans.

OXYGEN SENSORS

Galvanic Cell makes Good

from a Correspondent

SOME useful new developments in the measurement of partial pressures of oxygen were described when members of the Analytical Group of the Society of Analytical Chemistry met in London on March 12 to discuss oxygen sensors in biological and other systems. There has been growing interest in the direct measurement of the partial pressure of oxygen, particularly for medical purposes and in closed environments such as space capsules and mines. The polarographic oxygen electrode of Clark has been most commonly used to measure oxygen partial pressure in fluids.

Dr I. Bergman (Safety in Mines Research Establishment, Sheffield) pointed out that the galvanic oxygen electrode, which unlike the Clark electrode requires no external applied voltage to bring about the reduction of oxygen at the cathode, is essentially a polarographic device when operated in the gas diffusion controlled region. Research at the Safety in Mines Research Establishment has led to the development of several polarographic oxygen sensors in which a silver cathode is evaporated on to a polytetrafluoroethylene (PTFE) membrane. The anode is Ag/AgCl. In this way very efficient reduction of the incoming oxygen is achieved as well as a very fast response time. Bergman demonstrated an oxygen sensor which could be used to control the partial pressure of oxygen in an oxygen tent used in hospital during the care of premature babies.

Dr D. Parker and Mr A. Key (University College Hospital, London) reported the development of three silver-lead galvanic cells for measuring oxygen tension in blood. The first was a "flow-through" sensor which measured continuously the oxygen tension of blood flowing from a heart-lung machine to a patient undergoing heart surgery. The sensor electrodes were isolated from the blood by a PTFE membrane. Temperature compensation was incorporated in the device so that the cell output was linear in the range 20°–40° C for a pO_c from 0·710 mm Hg. The second sensor was a small probe used to determine glucose concentration in serum and urine. The glucose sample was added to an air-saturated glucose oxidase enzyme and the rate of consumption of oxygen measured by the oxygen sensor. The rate of consumption was proportional to the concentration of glucose initially present.

Key reported the development of an *in vivo* silver-lead galvanic oxygen sensor incorporated into the tip of a PTFE catheter of 0·8 mm diameter. A preformed PTFE membrane fits over the catheter tip. The catheter oxygen sensor is guided into the heart where the measurement of oxygen can be used to detect shunts across the chambers of the heart. The device could become a valuable diagnostic tool for the early detection of diseases of the heart.

There is a great deal of interest in galvanic cells as *in vivo* energy sources in which oxygen from the body fluids is converted directly to electrical power. In this way it is hoped to provide *in vivo* the energy to power cardiac pacemakers. At present, batteries implanted in the human body have a useful life of 18–24 months and thus their replacement necessitates expensive surgery about every two years. Dr A. C. C. Tseung (City University, London) reported the use of a platinum black–aluminium galvanic cell as an *in vivo* energy source. The cell electrolyte was an ionic ion-exchange membrane and the cell is encapsulated in silicone rubber. Such a cell planted subcutaneously near the abdominal wall of a rat gave a power output during intermittent use of 100 μW at 1·1 V for a total of 500 h. This was well above the objective of 30 μW at 1·1 V.

If the problem of the deposition of contaminants from the body on the cell membrane leading to a decrease in the membrane permeability for oxygen can be overcome, the galvanic cell promises seriously to rival present *in vivo* energy sources.

An Introduction to X-ray Crystallography

M. M. WOOLFSON

A text book for senior undergraduates and graduate students beginning a serious study of X-ray crystallography. An introductory chapter summarises the geometry of the crystalline state. Following chapters discuss scattering of X-rays, diffraction by crystals and factors affecting X-ray intensity. There is a chapter on the Fourier transform, describing mathematical techniques needed to make deductions about the arrangement of the scattering atoms from the scattered radiation, and a survey of the types of camera in common use. Finally, Professor Woolfson shows how these theories and techniques are applied to the determination of space groups and crystal structures.

The Computation of Chemical Equilibrium

F. van ZEGGEREN & S. H. STOREY

Methods for calculating the composition of a mixture of reacting compounds which has been allowed to come to equilibrium under new conditions, such as a given temperature and pressure, have been developed since the introduction of digital computers made realistic computations of this type feasible. This book provides a detailed critical survey of these methods, developed and published over the last 15-20 years. It is intended to assist those with a problem of this type to solve to select an appropriate method, and as a graduate level text in this area of theoretical thermodynamics.

A History of Bubonic Plague in the British Isles

J. F. D. SHREWSBURY

The story of the mortality, distress and fear caused by the Bubonic Plague, from the Great Pestilence of 1348 to the Plague of London in 1665. Professor Shrewsbury, a bacteriologist, describes how the disease was transmitted to man from its natural host the Black Rat. He also discusses the effects of plague on population growth and social and economic life, the harsh and useless regulations made in vain efforts to control it, and the collapse of law and order during its great outbursts.

Clerks and Craftsmen in China and the West

JOSEPH NEEDHAM, FRS

Dr Needham discusses astronomy and meteorology, metallurgy, engineering, nautical technology, alchemy, chemistry, pharmacy and medicine in this collection of essays, which are by-products of the research for his great work, 'Science and Civilisation in China'. All these topics are related to his major theme and constant preoccupation; the enormous and hitherto undervalued contribution of Chinese culture to world science and technology.

CAMBRIDGE UNIVERSITY PRESS

Water, Water Everywhere...

. . . nor any drop to drink?".

It has not reached that stage, yet. But there is growing concern over the pollution of drinking water in the closely populated areas of the world, and, far more serious, the pollution of the oceans and the sea-food which forms the diet of many millions of people.

One of the most serious effects of ocean pollution is the ruin and destruction of plankton — the food on which most of the creatures of the sea depend.

As part of the search for greater knowledge of the life processes of plankton, a renowned marine biologist has successfully measured their metabolic activity. This investigation called for an instrument with incredible sensitivity — the LKB FLOW MICROCALORIMETER. In fact, the LKB Flow Microcalorimeter sensitivity was such that successful measurements were made not only of concentrated solutions of plankton, but even of such diffuse solutions as normal sea-water.

A special feature of both the LKB Flow and Batch Microcalorimeters is the ease with which they can be set up and operated. Even the newcomer to calorimetry will find them easy to use, after only a very brief training session.

A-levels and University Performance

by

D. G. BAGG

Department of Chemical Engineering,
University of Manchester Institute
of Science and Technology

The principal factors which influence performance at the university and control 85 or 90 per cent of the variance of marks in the Part II examination are unrelated to A-level results.

MANY studies, mostly carried out in the United States, have sought to define the relationship between achievement at school and subsequent performance at university. In his survey of nearly three hundred such studies, Lavin points out[1] that "research is overwhelmingly of the static type", meaning that it investigates only "the prediction of performance at one point in time". Lavin strongly recommends "longitudinal" studies to cover the whole of the university course. This article describes such a study, giving my interpretation of results without many details of the statistical techniques used to obtain them. Briefly the principal technique is the analysis of the correlation matrices to obtain sets of multiple regression equations for each university examination and to show the different influences which affect the examination mark.

The influence of GCE A-levels on performance in university examinations can be said to be exerted in two distinct forms—the "direct" or "unique" influence peculiar to any particular A-level subject, and the "indirect" influence due to factors common to two or more A-level subjects. The indirect influence also includes factors common to the A-levels and such examinations as are included in the analysis which have occurred before that being considered. There are factors unrelated to the A-level subjects which are represented by the constant figures in the regression equations, and these factors can be seen to enlarge with progress through the course as A-levels are left further behind. This type of interpretation is given to the multiple regression equations presented in this article.

The Present Work

I have been concerned mostly with the performance of students in the Department of Chemical Engineering at the University of Manchester Institute of Science and Technology, where nearly a thousand student records are available. Similar techniques have also been applied to samples of records from the Departments of Civil and Mechanical Engineering in the Faculty of Science, and to samples of honours BA graduates from the schools of geography and history.

In all my work I have scaled the alphabetical grades of A-level pass numerically by conversion to "normalized T scores" which are based on frequency distribution and have a mean value of approximately fifty and a standard deviation of about ten. Knowledge of the actual scales is essential for the use of the regression equations, and those for the chemical engineering work are:

Grade of pass	*A*	*B*	*C*	*D*	*E*
Chemistry	62	52	46	40	32
Physics	66	56	48	44	35
Mathematics	66	56	49	42	34

Similar scales were prepared for other A-level subjects as the samples became available. The meaning of the regression equations given later can be illustrated easily by assuming a mean value of 50·0 for each A-level subject, multiplying this by the loading factor, and summing with the constant. It can then be seen that the proportion of the total mark which is contributed by the A-levels is large in the first examination but becomes less with progress through the university course, and is lower for the arts courses than for science and technology.

Chemical Engineering

I have analysed the records of 621 students who have graduated with honours in chemical engineering and of 116 who have graduated with ordinary degrees after taking the same course and examinations, the only difference being that at some point in the examinations they had not reached the standard demanded for honours graduation. The samples covered most of the students from the United Kingdom who graduated in the thirteen summers of 1957–69 inclusive. Overseas students presented quite a different picture in correlation[2], but the maximum size of sample, which is only $N = 65$, is really too small for the results of analysis to be fully valid. For those who wish to check the regression equations, the data for these two samples are given in Tables 1 to 4.

Table 1. RAW DATA FOR 621 HONOURS BSC GRADUATES IN CHEMICAL ENGINEERING

	A-level T scores			University percentage mark			
	Chemistry	Physics	Mathematics	Mid-session	Sessional	Part I finals	Part II finals

S.D.	8·518	8·844	9·362	11·866	9·482	9·386	8·085

Table 2. CORRELATION COEFFICIENTS FOR 621 HONOURS BSC GRADUATES IN CHEMICAL ENGINEERING

	Chemistry	Physics	Mathematics	Mid-session	Sessional	Part I
Physics	0·372	1				
Mathematics	0·199	0·282	1			
Mid-session	0·318	0·324	0·418	1		
Sessional	0·353	0·369	0·359	0·639	1	
Part I finals	0·261	0·309	0·302	0·507	0·627	1
Part II finals	0·206	0·293	0·238	0·465	0·532	0·669

I shall now examine performance session by session. For the first year mid-sessional examination the regression equation for the honours graduates is: mid-sessional mark $= 2{\cdot}185 + 0{\cdot}267 \times C + 0{\cdot}211 \times P + 0{\cdot}425 \times M$, where C, P and M denote the T scores of the appropriate A-level subjects, chemistry, physics and mathematics.

Evidently, mathematics is the A-level subject most closely related to this examination, one of the three papers actually being in mathematics. A second paper is in chemical engineering and the third is organic and physical chemistry, which apparently is moderately well correlated with the A-level paper. The lowish value for physics at this time is probably due to the small amount of chemical engineering which has so far been covered, this subject being sometimes termed "applied physics". The small size of the constant, 2·185, shows that altogether the three A-level grades of pass have a major controlling influence on performance at this stage.

For ordinary graduates a somewhat different equation is obtained

$$\text{mid-sessional mark} = -2{\cdot}424 + 0{\cdot}490 \times C + 0{\cdot}025 \times P + 0{\cdot}361 \times M$$

The first thing to note is that the constant, although of much the same absolute value as for the honours graduates, is negative, showing that there is a tendency for the

Table 3. RAW DATA FOR 116 ORDINARY BSC GRADUATES IN CHEMICAL ENGINEERING

	A-level T scores			University percentage mark			
	Chemistry	Physics	Mathematics	Mid-session	Sessional	Part I finals	Part II finals
Mean	47·276	47·750	47·138	38·885	42·571	42·378	51·397
S.D.	8·735	9·150	10·019	10·284	7·447	8·656	10·267

Table 4. CORRELATION COEFFICIENTS FOR 116 ORDINARY BSC GRADUATES IN CHEMICAL ENGINEERING

	Chemistry	Physics	Mathematics	Mid-session	Sessional	Part I
Physics	0·486	1				
Mathematics	0·111	0·079	1			
Mid-session	0·465	0·252	0·399	1		
Sessional	0·301	0·174	0·255	0·475	1	
Part I finals	−0·136	−0·155	0·039	0·101	−0·149	1
Part II finals	0·033	−0·089	0·031	0·239	0·163	0·551

A-level grades to overestimate performance at this examination. The discrepancy between the loading factors for chemistry and physics suggests to me the predominance of aptness in chemistry but inaptitude in physics. Perhaps these students take longer to "get into their stride" with the course, and their numerical facility, presumably, was not quite so good as that of the honours students.

The regression equation for the first year sessional examination and for subsequent examination marks can be expressed in two forms. The first includes the influence of the mid-sessional examination mark, denoted by MS, and the second contains this influence algebraically converted into that of the A-levels, by means of the equation given earlier. The first form then shows the influence, unique plus indirect, of the A-levels on this examination, and the second form includes their influence on the previous examination, showing the overall total influence of the A-levels on the first year sessionals.

For the honours graduates these two equations are

$$\text{sessional mark} = 18{\cdot}133 + 0{\cdot}135 \times C + 0{\cdot}141 \times P + 0{\cdot}079 \times M + 0{\cdot}419 \times \text{MS} \tag{1}$$

$$\text{sessional mark} = 19{\cdot}049 + 0{\cdot}247 \times C + 0{\cdot}229 \times P + 0{\cdot}258 \times M \tag{2}$$

The first point to note is that the constant is much larger than for the mid-sessional examinations, showing that factors independent of previous examination results are beginning noticeably to affect performance, and by far the largest loading factor is for the immediately preceding examination; this point is noticeable throughout the equations in this article.

In equation (1) the influence of mathematics is very small, evidently exerted indirectly through the mid-sessional examination, as shown by its increase from 0·079 to 0·258 in equation (2). The overall influence of each A-level subject is nearly equal.

For the ordinary graduates the corresponding equations are

$$\text{sessional mark} = 23{\cdot}717 + 0{\cdot}085 \times C + 0{\cdot}017 \times P + 0{\cdot}065 \times M + 0{\cdot}281 \times \text{MS} \tag{1}$$

$$\text{sessional mark} = 23{\cdot}036 + 0{\cdot}223 \times C + 0{\cdot}024 \times P + 0{\cdot}167 \times M \tag{2}$$

The constant is appreciably larger than for the honours graduates, indicating that the influence of external factors or factors other than A-levels is a greater proportion of the total. Equation (1) shows that the direct A-level influence, particularly of physics, is lower, and in equation (2) the difference between the factors for chemistry and physics is again very noticeable, as for the mid-sessional mark. Apparently, students who will eventually become only ordinary graduates are continuing to show an inaptitude for physics. The reduced factor for the mathematics predictor certainly suggests less numerical facility than for the honours graduates, and my comments about the mid-sessional discrepancies also apply here.

For the honours graduates the equations for the part I finals mark are

$$\text{part I mark} = 17{\cdot}741 + 0{\cdot}009 \times C - 0{\cdot}069 \times P + 0{\cdot}043 \times M + 0{\cdot}123 \times \text{MS} + 0{\cdot}480 \times \text{S} \tag{1}$$

$$\text{part I mark} = 27{\cdot}159 + 0{\cdot}160 \times C + 0{\cdot}205 \times P + 0{\cdot}219 \times M \tag{2}$$

Equation (1) indicates that the direct influence of each of the three A-level subjects is very considerably reduced at this stage, the loading factors being so small that "errors of chance" might conceivably predominate. Most of their influence is now indirect, in factors common to more than one of the variables. This is shown by the algebraic substitution in equation (2), where the influence of the mid-sessionals and the sessionals (S) is analysed into an increase in the constant as well as in the total influence of each A-level subject. The value of the constant, now about 27, shows an increase in the influence of factors unrelated to the A-levels, the constant for the sessional examinations being only about 19.

For the ordinary graduates, these equations are

$$\text{part I mark} = 56{\cdot}119 - 0{\cdot}153 \times C - 0{\cdot}112 \times P - 0{\cdot}000 \times M + 0{\cdot}262 \times \text{MS} - 0{\cdot}267 \times \text{S} \tag{1}$$

$$\text{part I mark} = 49{\cdot}326 - 0{\cdot}084 \times C - 0{\cdot}112 \times P + 0{\cdot}050 \times M \tag{2}$$

In both these equations, the constant is larger than the mean part I finals mark, which is 42·278, showing that the overall performance of the ordinary graduates in this examination is quite inconsistent with previous performance and that the factors controlling this performance must be largely unrelated to the original A-level results. In equation (1) the loading factor for mathematics is actually −0·0002.

For the honours graduates, these equations for the part II finals examination are

$$\text{part II mark} = 23{\cdot}309 - 0{\cdot}031 \times C + 0{\cdot}060 \times P - 0{\cdot}024 \times M + 0{\cdot}082 \times \text{MS} + 0{\cdot}104 \times \text{S} + 0{\cdot}455 \times \text{pt. I} \tag{1}$$

$$\text{part II mark} = 37{\cdot}826 + 0{\cdot}090 \times C + 0{\cdot}195 \times P + 0{\cdot}138 \times M \tag{2}$$

Evidently, by this time, the direct influence of the A-level predictors is small enough probably to be mostly "errors of chance", being shown in equation (1) as positive and negative factors of minor value. Equation (2) shows that the overall influence of the three A-level predictors on the performance of the honours graduates is not very large, the constant comprising the external factors being about 64 per cent of the mean mark of 59·168. A-level physics has the largest influence of the A-levels on part II honours finals, and chemistry has the least.

For the ordinary graduates we now have

$$\text{part II mark} = 12{\cdot}158 + 0{\cdot}046 \times C - 0{\cdot}090 \times P - 0{\cdot}094 \times M + 0{\cdot}188 \times \text{MS} + 0{\cdot}299 \times \text{S} + 0{\cdot}673 \times \text{pt. I} \tag{1}$$

$$\text{part II mark} = 51{\cdot}962 + 0{\cdot}114 \times C - 0{\cdot}155 \times P + 0{\cdot}032 \times M \tag{2}$$

Equation (2) shows that, with a constant of almost exactly the mean part II mark of 51·397, the overall influence of the three A-level subjects on the performance of the ordinary graduates in the final examinations is practically zero, and the positive and negative loading factors must be accounted for as errors of chance resulting from the erratic and inconsistent performance of these students, which is evident from their departmental records. The factors controlling their performance in finals must be almost, if not quite, unrelated to A-levels and strongly related to the "external" factors which controlled their performance in part I, for the loading factor for that examination mark in equation (1) is large – 0·673.

Civil Engineering

I have used the records of all 174 graduates in this subject for the four summers of 1965–68. I found it practical to take only two A-level subjects, physics and mathematics, for the third varied, being chemistry, applied mathematics, or further mathematics. It was not practical to separate the honours from the ordinary graduates, there being relatively few of the latter.

The equation relating the physics and mathematics A-level grades of pass to the first year mid-sessional examination performance of civil engineering students is:

$$\text{mid-sessional mark} = 14{\cdot}330 + 0{\cdot}386 \times P + 0{\cdot}262 \times M.$$

The mean mark of 48·218 is moderately controlled by the A-level results, physics having a somewhat larger influence than mathematics. The constant of 14·330 indicates a larger proportion of factors external to these two A-levels in this examination than for the chemical engineering honours graduates, for whom this constant was only 2·185.

The equations for the first year sessional examination taken by civil engineering students are

$$\text{sessional mark} = 13{\cdot}360 + 0{\cdot}107 \times P + 0{\cdot}183 \times M + 0{\cdot}558 \times \text{MS} \quad (1)$$

$$\text{sessional mark} = 21{\cdot}349 + 0{\cdot}322 \times P + 0{\cdot}330 \times M \quad (2)$$

In equation (1) the direct influence of each A-level subject is less than that on the mid-sessional mark, although equation (2) shows that the overall influence of mathematics has increased, with a slight reduction in that of physics. The increase in the constant of equation (2) over that in the equation for the mid-sessional examination is almost exactly equal to the increase in the mean mark to 55·408, this increase therefore being an influx of factors external to the A-levels, the overall influence of which has scarcely changed with time.

For the second year examination, the equations for civil engineering students are

$$\text{second year mark} = 15{\cdot}146 - 0{\cdot}009 \times P + 0{\cdot}015 \times M + 0{\cdot}151 \times \text{MS} + 0{\cdot}620 \times \text{S} \quad (1)$$

$$\text{second year mark} = 30{\cdot}543 + 0{\cdot}249 \times P + 0{\cdot}259 \times M \quad (2)$$

From equation (1) it can be deduced that the direct influence of the A-levels is approaching zero. Equation (2) shows that the overall influence of the A-levels is somewhat reduced at this time and that the "external" factors become more predominant, amounting to a little more than half of the mean mark, which is 57·058.

For the third year final examination in civil engineering, the equations are

$$\text{final mark} = 20{\cdot}618 + 0{\cdot}100 \times P - 0{\cdot}003 \times M + 0{\cdot}053 \times \text{MS} + 0{\cdot}052 \times \text{S} + 0{\cdot}431 \times \text{2nd yr} \quad (1)$$

$$\text{final mark} = 35{\cdot}642 + 0{\cdot}244 \times P + 0{\cdot}139 \times M \quad (2)$$

The direct influence of A-level mathematics on the civil engineering finals mark is practically zero, and that of physics is only small, contributing, say, five marks to the total. The overall influence of physics, however, is just about equal to that in the second year examination, with that of mathematics reduced by nearly 50 per cent. With a mean mark of 58·552, the A-levels contribute in total almost 40 per cent to civil engineering finals, the influence of physics being nearly twice that of mathematics.

Mechanical Engineering

I used the records of 113 students of mechanical engineering who graduated in the four summers of 1965–68. Again, it was practical to use only A-level physics and mathematics in the correlation. For the first year mid-sessional examination the regression equation is

$$\text{mid-sessional mark} = 24{\cdot}835 + 0{\cdot}236 \times P + 0{\cdot}221 \times M$$

The constant is larger than for the other samples I have discussed, being just about half of the mean mark of 48·664, which indicates fairly strong influence of factors other than the A-levels quite early in the course.

For the second examination in mechanical engineering (the first year sessional examination) the equations are

$$\text{sessional mark} = 10{\cdot}712 + 0{\cdot}136 \times P + 0{\cdot}129 \times M + 0{\cdot}661 \times \text{MS} \quad (1)$$

$$\text{sessional mark} = 27{\cdot}138 + 0{\cdot}293 \times P + 0{\cdot}274 \times M \quad (2)$$

The direct influence of the A-levels is reduced a little, although their indirect influence through the mid-sessional examination makes their total influence a little greater than before. The increase in the constant of equation (2) over that of the mid-sessional equation is less than half of the increase in the mean mark to 56·726, so that the influence of factors unrelated to A-levels is, if anything, less than in the mid-sessional examinations.

For the second year examination in mechanical engineering the equations are

$$\text{second year mark} = 18{\cdot}056 - 0{\cdot}009 \times P + 0{\cdot}023 \times M + 0{\cdot}239 \times \text{MS} + 0{\cdot}442 \times \text{S} \quad (1)$$

$$\text{second year mark} = 35{\cdot}999 + 0{\cdot}177 \times P + 0{\cdot}197 \times M \quad (2)$$

The direct influence of physics is practically zero, and that of mathematics is very small. The overall influence of the A-levels is substantially less than for the first year, and the increased constant indicates a growth in the factors unrelated to the A-levels.

For the third year final examination in mechanical engineering the equations are

$$\text{finals mark} = 30{\cdot}856 + 0{\cdot}027 \times P - 0{\cdot}055 \times M + 0{\cdot}246 \times \text{MS} + 0{\cdot}071 \times \text{S} + 0{\cdot}204 \times \text{2nd yr} \quad (1)$$

$$\text{finals mark} = 46{\cdot}229 + 0{\cdot}142 \times P + 0{\cdot}058 \times M \quad (2)$$

The direct influence of the A-levels, with one positive and the other negative together with the small size of the sample (113), is only of the order of errors of chance, and their indirect influence is small, amounting to about 17 per cent of the mean mark of 56·655. The total influence of A-level physics on the final examination in mechanical engineering is apparently two and a half times that of A-level mathematics.

Geography and History

I used the records of 116 honours BA graduates in geography. A-level predictors were restricted to geography and history because of variations in the third subject, but I included GCE O-level grades of pass in both geography and history, and these are included in the equations, using similar scales of normalized T scores. To distinguish the O-level from the A-level items, I have used the initials *OG*, *OH*, *AG* and *AH* in the equations.

The equation for the prediction of the first year sessional examination mark in geography is

$$\text{sessional mark} = 50{\cdot}208 - 0{\cdot}009 \times OG - 0{\cdot}014 \times OH + 0{\cdot}029 \times AG + 0{\cdot}063 \times AH$$

The overall influence of O-level and A-level subjects taken together is almost zero, these four predictors adding only 3·4 marks to the constant for the mean mark of 53·616. If O-level predictors are omitted, this equation becomes

$$\text{sessional mark} = 49{\cdot}619 + 0{\cdot}025 \times AG + 0{\cdot}055 \times AH$$

Although the influence of the A-levels is very small, that of history is twice that of geography.

For part I finals in geography (second year), the equations are

$$\text{part I} = 36{\cdot}926 - 0{\cdot}114 \times OG + 0{\cdot}252 \times OH + 0{\cdot}064 \times AG - 0{\cdot}131 \times AH + 0{\cdot}233 \times S \quad (1)$$

$$\text{part I} = 48{\cdot}620 - 0{\cdot}116 \times OG + 0{\cdot}249 \times OH + 0{\cdot}071 \times AG - 0{\cdot}116 \times AH \quad (2)$$

Although the overall effect of the GCE predictors is only about four marks at the mean point, the apparently strong influence of O-level history in this examination is surprising and difficult to explain without a detailed study of the two sets of examination questions, unless it is an "error of chance". Omitting the O-level predictors from equation (2) gives

$$\text{part I mark} = 49{\cdot}548 + 0{\cdot}103 \times AG - 0{\cdot}040 \times AH \quad (3)$$

In this case the total influence of the A-levels is only about three marks.

The equations for the part II final examinations in geography are

$$\text{part II mark} = 24{\cdot}970 + 0{\cdot}055 \times OG - 0{\cdot}141 \times OH + 0{\cdot}014 \times AG + 0{\cdot}082 \times AH + 0{\cdot}173 \times S + 0{\cdot}457 \times \text{pt. I} \quad (1)$$

$$\text{part II mark} = 55{\cdot}865 - 0{\cdot}000 \times OG - 0{\cdot}029 \times OH + 0{\cdot}052 \times AG + 0{\cdot}039 \times AH \quad (2)$$

Since the mean part II mark is 58·959, the overall influence of the O-level and A-levels is the addition of only about three marks to the constant at the mean point, and the finals mark is controlled chiefly by factors unrelated to the GCE examinations. Omitting the O-level predictors from the part II equation gives

$$\text{part II mark} = 55{\cdot}282 + 0{\cdot}046 \times AG + 0{\cdot}027 \times AH \quad (3)$$

The total influence of the two A-levels is then nearly four marks, of which history contributes a little more than one-third.

A small sample, from two sessions, of eighty-one honours BA graduates in history has been analysed, with data somewhat more limited than for the previous samples. The records of two A-level subjects, history and English, were taken, but a third was again too variable for use. Analysis of the first year examination results was found to be impractical, and the equation for the part I final examination is

$$\text{part I mark} = 48{\cdot}457 + 0{\cdot}065 \times H + 0{\cdot}037 \times E$$

The direct influence of the two A-level subjects is enough to add only about five marks to the constant which includes any indirect A-level influence through the first year examinations.

With the part II final examination, the influence of A-level history amounts to about 12 per cent of the mean mark, the equations being

$$\text{part II mark} = 15{\cdot}040 + 0{\cdot}093 \times H - 0{\cdot}027 \times E + 0{\cdot}724 \times \text{pt. I} \quad (1)$$

$$\text{part II mark} = 50{\cdot}108 + 0{\cdot}140 \times H - 0{\cdot}0005 \times E \quad (2)$$

Performance in part I finals clearly has a large influence on the part II finals result in history, perhaps larger than in some other courses. This figure may be affected by the absence of figures for the first year examinations, which I was not able to obtain.

Influence of A-level Diminishes

My first conclusion from this work is that, although the influence of the A-levels on the first year mid-sessional examinations is quite appreciable, this influence diminishes with progress through the 3 years of the university course until it is of no real importance in the part II final examinations. The first examination at the university is usually held about 7 months after the A-level examinations, and the student is presumably still using some of the knowledge which he gained at school, the university syllabus not at that point being very far ahead of the A-level limits. By the end of the course, there is probably little real connexion between the subject matter of the finals examination and that of the A-levels.

My principal conclusion is that A-level grades of pass form an unreliable and possibly hazardous assessment, or prediction of the future academic performance, of a candidate. Such an examination mark is scarcely a measure of the subject by which it is labelled, but is more a measure of the various specific abilities used by the candidate for the application of his knowledge to the questions. In addition, this measure will include an element measuring the efficiency of the school teaching, in its coverage of syllabus and communication with the student. I believe that the admissions tutor may fall into a trap, particularly in the case of a candidate from a school which indulges in "cramming", for the A-level grade may be a close approximation to a measure of the "ceiling of attainment" or "maximum cognitive capacity" of that student in that subject. Such is the only explanation I have for the cases of students who have entered the university with, say, three grade *A* passes, but whose performance has deteriorated to ultimate failure in part II finals. It is sometimes said that the reason for such performance is simply that the student "did not work", but to me this is not a reason but a statement of what happened, and a reason for the lack of ability to work is required. Maybe such a student has reached his limits in that type of subject after A-level and should transfer his studies to a school better suited to his abilities. The existence of such a "ceiling of attainment" is quite widely recognized, if only subconsciously, as is illustrated by the remark "Oh ! I'm not mathematical" which I have often heard.

The "specific abilities" to which I have referred are elements such as verbal fluency, numerical facility, spatial ability, logical reasoning, vocabulary, and so on, but the measurement of such abilities by A-level grades of pass has not been established in detail, nor has their identification in the various university examinations. We do not know whether for the assessment of a prospective student the more important factor is the quantity of his knowledge of a subject before admission, or whether it would be better to assess his ability towards the future application of such knowledge of that subject as will be acquired after admission, his previous knowledge of that subject then being only of minor importance. Such a distinction might perhaps be described as a balance between memory ability on the one hand and cognitive capacity on the other, bearing in mind that "memory" is not always synonymous with the "comprehension" of the matter memorized.

Reinitiation of RNA Chain Synthesis *in vitro*

by
JOHN P. RICHARDSON[*]
Institut de Biologie Moléculaire,
Université de Genève,
Geneva

During transcription of bacteriophage T4 or T5 DNA in 0·2 M KCl, RNA polymerase is able to terminate the synthesis of RNA chains, dissociate from the DNA template and reinitiate new RNA chains on new DNA templates.

THE complete process of RNA transcription in the cell involves initiation, polymerization, termination and release of specific RNA molecules. Some of these steps are also characteristic of the reaction catalysed by RNA polymerase *in vitro*; when T4 or λ phage DNA is the template, the purified enzyme from *Escherichia coli* is capable of specific initiation[1-4] and rapid polymerization of RNA chains[5]. There is, however, some question whether this reaction also includes termination and release of the RNA.

During synthesis at low salt concentration ($I < 0·1$), it is evident that there is some defect either in the termination or in the release of the RNA: synthesis usually ceases completely after only 60 min[6] and each enzyme initiates only one RNA chain that is rarely released from its synthetic complex with enzyme and DNA[7-9]. At higher salt concentrations, however, RNA synthesis can continue for several hours[10,11], suggesting that salt may overcome the defect. I demonstrate here that during synthesis of T4 RNA in 0·2 M KCl, each RNA polymerase molecule can initiate more than one RNA chain; further, the enzyme molecule can be released from its DNA template and reinitiate a new RNA chain on a new DNA template. Thus, in these conditions of synthesis, the RNA polymerase catalysed reaction is functionally complete, and continued synthesis is the outcome of repetitions of the transcription cycle.

It has been shown recently by Roberts[12] that *E. coli* possesses a protein factor called ρ that causes specific termination and release of λ RNA molecules in an *in vitro* reaction. From the existing evidence, however, it seems that the termination and release that occur in 0·2 M KCl are different from those mediated by ρ. It is thus of interest to learn more about the termination that occurs in high salt concentration in the absence of ρ, for it may also have some significance in the control of RNA transcription.

Kinetics and Stoichiometry of Initiation

RNA chain initiation was assayed by measuring the incorporation of γ-^{32}P-ribonucleoside triphosphates into RNA[8]. In 0·05 M KCl (Fig. 1*a*), most T4 RNA chains are initiated in the first few minutes of synthesis, and after 20 min there is no further initiation even though there is still appreciable RNA synthesis at that time. In 0·2 M KCl (Fig. 1*b*), however, not only does total RNA synthesis continue for a much longer time, but so does the initiation of new chains. The yield of synthesis after 160 min, which is three-fold greater at the higher salt concentration, is nearly matched by the 2·6-fold increase in the number of chains initiated. Similar findings have been reported recently by Millette[13] and by Maitra and Barash[14].

From the data in Fig. 1, it is possible to estimate the number-average length of the RNA chains initiated, and thus determine whether the salt concentration also influences the size of the RNA synthesized. After 60 min, when there is no further increase in the average length of the RNA in either case, the RNA made at 0·2 M KCl is, on

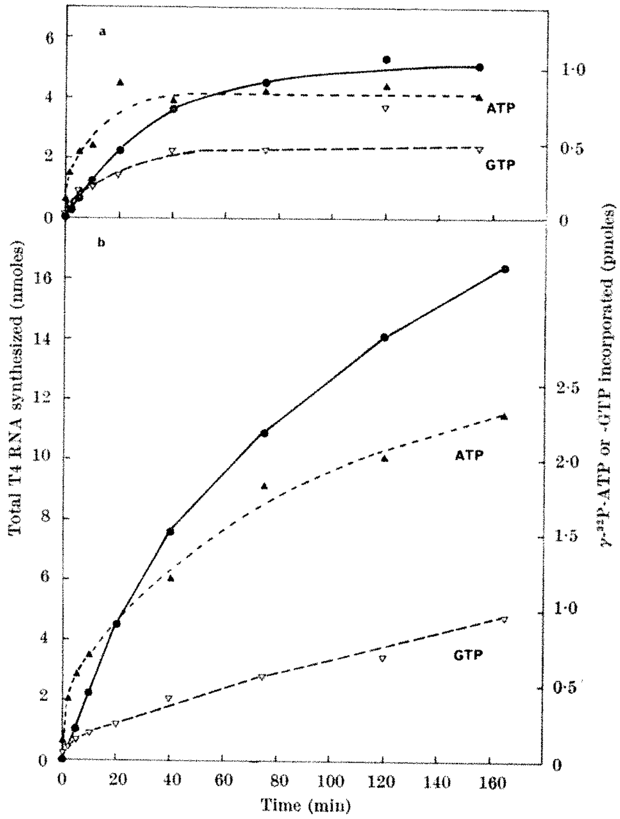

Fig. 1. Effect of salt concentration on RNA chain initiation. Reaction mixtures of 0·1 ml. contained 0·04 M Tris-HCl (*p*H 7·9) buffer; 0·012 M $MgCl_2$; 0·2 mM ATP, GTP, UTP and CTP; 1·1 mM 2-mercaptoethanol; 0·1 mM EDTA; 0·2 mg/ml. bovine serum albumin; 4·7 μg T4 DNA (prepared by the method of Thomas and Abelson[28]); 1·0 μg hydroxylapatite fraction *E. coli* MRE 600 RNA polymerase (prepared by the method of Richardson[15]); and either (*a*) 0·05 or (*b*) 0·2 M KCl. Separate mixtures contained either γ-^{32}P-ATP (0·89 × 10^3 c.p.m./pmole); or γ-^{32}P-GTP (0·83 × 10^3 c.p.m./pmole) all contained ^{14}C-UTP (1·9 × 10^3 c.p.m./nmole). The γ-^{32}P-nucleoside triphosphates were prepared by the method of Glynn and Chappell[29] and ^{14}C-UTP was purchased from Schwarz BioResearch. Reaction mixtures were incubated at 37° C and RNA synthesis was terminated at the specified times by adding rapidly at 0° C: 0·35 ml. H_2O; 0·05 ml. 25 mM ATP or GTP (depending on which is labelled with ^{32}P in the reaction mixture); 0·1 ml. 1 per cent bovine serum albumin; and 0·5 ml. 5 per cent trichloroacetic acid. After 5 min at 0° C, the precipitate was collected by centrifugation (10 min at 1,500*g*) and redissolved in 0·5 ml. 0·1 M $Na_4P_2O_7$ plus 0·05 ml. 25 mM ATP or GTP. After reprecipitation of the RNA, this washing procedure was repeated once more and the precipitate formed, after adding trichloroacetic acid for the third time, was collected on a Whatman 'GF/C' filter (2·5 cm diameter) and washed on the filter with 10 ml. 2 per cent trichloroacetic acid containing 1 per cent $Na_4P_2O_7$–10 H_2O and 0·5 per cent NaH_2PO_4 and with 1 ml. ethanol. After drying, the filter was placed in a plastic vial containing 5 ml. PPO-POPOP-toluene scintillation fluid and radioactivity was counted in a Packard 'Tri-Carb' liquid scintillation counter. Incorporation of all labelled substrates was completely dependent on both enzyme and DNA. The levels of unincorporated ^{32}P were equivalent to 0·17 and 0·16 pmoles, respectively, of ATP and GTP, and the data given in the figure have been corrected for these background values. The total incorporation of γ-^{32}P-UTP and γ-^{32}P-CTP into RNA, measured separately in other experiments, was less than 5 per cent of the total initiation in all cases. Total nucleotide incorporation was calculated from the value of ^{14}C-UTP incorporated assuming that the mole fraction of UMP in the T4 RNA synthesized was 0·29 (ref. 30). ●, Total nucleotide incorporation; ▲, incorporation of γ-^{32}P-ATP; ▽, incorporation of γ-^{32}P-GTP.

---

[*] Present address: Department of Genetics, University of Washington, Seattle, Washington 98105.

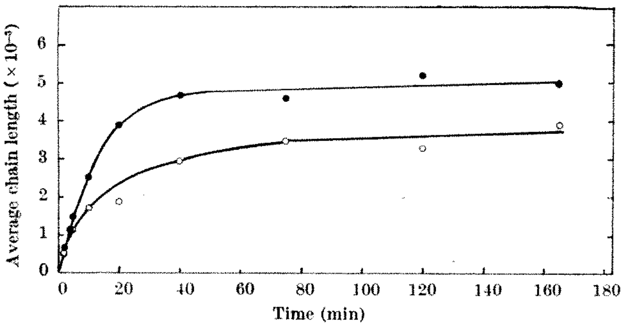

Fig. 2. Average chain lengths of T4 RNA as a function of the time of synthesis. These values are calculated from the data in Fig. 1; each point is the ratio of the total nucleotide incorporation divided by the sum of the γ-^{32}P-ATP and γ-^{32}P-GTP incorporated. ○, In 0·05 M KCl; ●, in 0·2 M KCl.

the average, 1·3 times larger than that made at 0·05 M KCl (Fig. 2). Thus salt concentration does affect the average size of the RNA synthesized, but not to the same extent as it affects the number of chains initiated. Furthermore, the fact that the average length of RNA synthesized in 0·2 M KCl is constant after 60 min indicates that further RNA synthesis after that time is a direct consequence of continued initiation.

To show that continued initiation in 0·2 M KCl reflects reinitiation rather than a slow activation of enzyme molecules that do not function in 0·05 M KCl, it is necessary to consider the molar yields of the reaction. In the experiment shown in Fig. 1*b*, a total of 3·3 pmoles of γ-^{32}P-ATP and γ-^{32}P-GTP had been incorporated after 165 min in 0·1 ml. of a reaction containing 1 µg of enzyme protein (determined using 0·65 as the specific absorbance of purified RNA polymerase at 280 nm, ref. 15). After 5 h of synthesis, this value increased further to 4·4 pmoles. Because the particle weight of the active unit of RNA polymerase is believed to be in the range 400,000 to 500,000 daltons[15–18], this yield indicates that at least 1·7 chains have been initiated per enzyme molecule after 5 h synthesis in 0·2 M KCl.

When T5 DNA was used as template instead of T4 DNA, the yield was even greater. After 4 h synthesis at 30° C in 0·2 M KCl, 0·6 µg of RNA polymerase catalysed the incorporation of 3·2 and 0·3 pmoles of γ-^{32}P-ATP and γ-^{32}P-GTP, respectively, which is equivalent to at least 2·3 T5 RNA chains per enzyme molecule. Because the RNA polymerase preparations used may have contained some inactive protein, the yields are only minimal estimates. The number of chains initiated per active enzyme molecule is probably even higher.

Evidence for Reinitiation on a New DNA Template

During synthesis at low salt concentrations, nearly all enzyme molecules become irreversibly attached to the DNA template within the first few minutes of incubation[19]. It is possible, however, that in conditions in which reinitiation occurs, enzyme molecules dissociate from the template before initiating new RNA chains. If the enzyme molecules dissociate, they should then be free to transcribe a second DNA species added at a later time. The following experiment suggests that many of the RNA polymerase molecules are released from the DNA template molecules during transcription in 0·2 M KCl.

When RNA polymerase is added to a mixture of T4 and T5 DNA, it transcribes T5 DNA with a slight preference that is nearly the same in both 0·05 and 0·2 M KCl (Table 1). But if the enzyme is preincubated with one DNA template for 10 min in a complete reaction mixture before adding the other, the salt concentration strongly influences the fractions of RNA specific to the two DNAs. In 0·05 M KCl, very little RNA is transcribed from the second DNA, whereas in 0·2 M KCl the fractions are much closer to the values found in the experiment without preincubation. The total amount of RNA synthesized is also greater in 0·2 M KCl, so it is concluded that many more enzyme molecules are free at the higher salt concentration to initiate RNA chains on a DNA template added at a later time.

Table 1. TRANSCRIPTION OF T4 AND T5 DNA MIXTURES

Exp.	DNA present during preincubation	DNA added after 10 min	KCl concentration (M)	^{3}H-UMP incorporated per 5 µl. (c.p.m.)	Fraction of RNA made between 10 and 20 min (per cent) T4	T5
1	T4 + T5	—	0·05	542	45	55
	T4 + T5	—	0·20	1,100	40	60
2	T5	T4	0·05	354	5	95
	T5	T4	0·20	775	19	81
3	T4	T5	0·05	486	88	12
	T4	T5	0·20	968	70	30

Each reaction mixture of 0·1 ml. contained initially 0·04 M Tris-HCl buffer (*p*H 7·9); 12 mM $MgCl_2$; 2·8 mM 2-mercaptoethanol; 0·05 mM EDTA; 0·66 mM each of ATP, GTP and CTP; 0·2 mM UTP; 2·5 µg of DNA (either T4 or T5); and 1·3 µg of RNA polymerase. After incubation for 10 min at 37° C, 2·5 µg of a second DNA (in 10 µl.) and 2 µCi of ^{3}H-UTP (1·2 Ci/mmole in 5 µl.) were added and the incubation was continued for a further 10 min at 37° C. RNA synthesis was stopped by adding 0·4 ml. of 0·5 per cent sodium dodecyl sulphate containing 0·12 M sodium acetate buffer (*p*H 5·2). After incubation for 3 min at 37° C, a 5 µl. sample was removed to assay the total incorporation of ^{3}H-UTP into acid insoluble material, and the proteins in the remaining solution were extracted by the hot-phenol method of Scherrer and Darnell[31]. Unincorporated nucleoside triphosphates were removed after phenol extraction by dialysis for 15 h against 0·3 M NaCl containing 0·03 M trisodium citrate. The fractions of RNA specific to T4 and T5 DNAs were estimated by the RNA-DNA hybrid assay procedure described by Gillespie and Spiegelman[32]. Membrane filters (Sartorius 'MF 50') with 2 µg of alkali-denatured DNA or with no DNA were annealed with RNA (approximately 3,500 c.p.m.) in 1·1 ml. of 0·3 M NaCl containing 0·03 M trisodium citrate for 20 h at 65° C. Each RNA preparation was annealed in duplicate to T4 DNA, T5 DNA and a blank filter. The amount of RNA remaining on each DNA filter was corrected first by subtracting the amount on the blank (< 0·4 per cent of c.p.m. added), then by dividing by the efficiency of hybridization to that filter (determined with preparations of pure T4 and T5 RNA: 0·27 for T4 DNA and 0·35 for T5 DNA). The fractions (as per cent) are the ratios of the corrected value for hybridization to each filter over the total of the corrected values. In all cases the total of the corrected values was within 10 per cent of the total amount of RNA added.

Although this result is expected if enzyme molecules dissociate from the DNA before initiating new RNA chains, a similar effect might have been seen if RNA chain initiation were much slower in 0·2 M KCl. The initial rate of RNA synthesis and the rate of RNA chain growth are both about 1·3 times higher in 0·2 M KCl than in 0·05 M KCl[5], however, so that there is probably very little difference in the rates of initiation. It is therefore much more likely that the increase in transcription in 0·2 M KCl

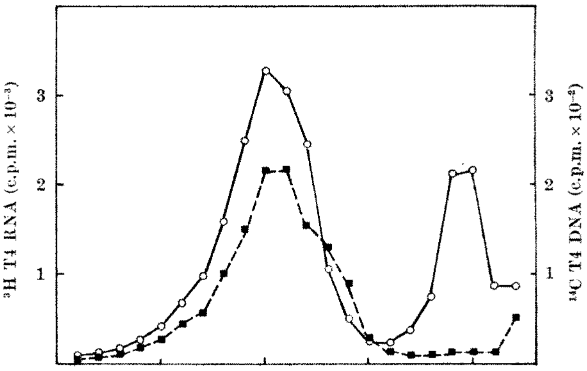

Fig. 3. Stability of the RNA polymerase–nascent RNA–T4 DNA complex in 0·3 M KCl. The reaction mixture was the same as that containing 0·2 M KCl described in Fig. 1, but with the following modifications: ^{3}H-UTP was the labelled nucleoside triphosphate (12 Ci/mole) and initially the mixture contained 6·2 µg T4 ^{14}C-DNA (416 c.p.m./µg) and 3·8 µg RNA polymerase in a total volume of 0·1 ml. After incubating for 3 min at 37° C, the reaction mixture was diluted with 1·4 ml. of an ice-cold solution of 0·3 M KCl containing 0·01 M Tris-HCl (*p*H 7·9) buffer, 0·01 M $MgCl_2$, 0·5 mM 2-mercaptoethanol, 0·05 mM EDTA and 0·2 mg/ml. bovine serum albumin ("gradient buffer") and was layered on a 35 ml. 10 to 30 per cent linear glycerol gradient in the same buffer. After centrifugation for 4 h at 27,000 r.p.m. in a Spinco '*SW* 27' rotor, the gradient was fractionated by pumping the solution from the bottom of the tube at a rate of 3·1 ml./min. Fractions of 1·6 ml. were collected in tubes containing one drop of 0·5 per cent bovine serum albumin and precipitated with 0·6 ml. 16 per cent trichloroacetic acid. The precipitates were collected on Whatman 'GF/C' filters and radioactivity was counted as described in Fig. 1. The recoveries of applied material were 89 per cent for ^{3}H-RNA and 71 per cent for the T4 ^{14}C-DNA. ○, ^{3}H-RNA; ■, T4 ^{14}C-DNA.

of a DNA added later is a reflexion of a greater rate of release of enzyme molecules previously attached to the first DNA template.

Continued Synthesis with Enzyme–Nascent RNA–DNA Complex

When an RNA polymerase molecule has initiated synthesis of an RNA chain on T4 DNA, it forms a stable complex with the template and nascent RNA chain[9]. This complex sediments much faster than free RNA polymerase, and it is sufficiently stable to be isolated by zone centrifugation on a glycerol gradient containing 0·3 M KCl (Fig. 3). RNA polymerase can also bind to T4 DNA in the absence of ribonucleoside triphosphate substrates, but this binary complex is much less stable and dissociates completely in 0·3 M KCl (ref. 20 and personal communication from G. Cassani). Consequently, the ternary complex isolated in 0·3 M KCl should be free of enzyme molecules that have not initiated RNA chains.

The enzyme in the complex with nascent RNA and T4 DNA isolated in this way does retain some RNA synthetic activity, but by itself it is apparently unable to initiate new RNA chains even in 0·2 M KCl. The kinetics of synthesis are the same in 0·06 M KCl and in 0·2 M KCl: in both cases, synthesis stops very rapidly (Fig. 4). Further, the enzyme in the complex is unable to transcribe added T5 DNA (Table 2, experiment 1). The possibility that the DNA in the complex is altered is ruled out by the fact that free RNA polymerase added to this same mixture transcribes both T4 and T5 DNA with the usual preference ratio (Table 2, experiment 2). It seems therefore that the enzyme is defective.

The possible nature of the defect is suggested by the fact that *E. coli* RNA polymerase requires a protein factor known as σ for the initiation of RNA chains from T4 or T5 DNA (ref. 21 and personal communication from G. Hager). Normally, σ is associated with the enzyme, but there is some indication that it may be released after the enzyme initiates an RNA chain[17,22], in which case it could be separated from the enzyme on the glycerol gradient containing 0·3 M KCl. Because of this possibility, the effect of added σ was tested, and the results show that it does stimulate RNA synthesis, particularly in 0·2 M KCl, and that it does allow the enzyme to transcribe T5 DNA (Table 2, experiment 3). Thus the RNA polymerase in the isolated complex is able to initiate new RNA chains, but only in the presence of σ-factor. Further, the fact that the enzyme in the complex is deficient in active σ-factor is consistent with the interpretation that σ is released after RNA chain initiation.

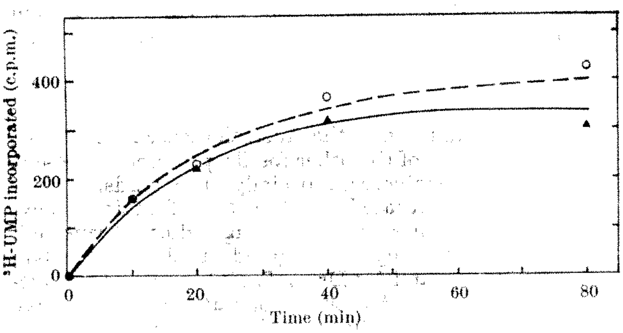

Fig. 4. Kinetics of RNA synthesis with complex. The nascent RNA–RNA polymerase–T4 DNA complex was prepared by the procedure described in Fig. 3, except that the reaction mixture of 0·3 ml. contained 15·6 μg T4 ^{32}P-DNA (950 c.p.m./μg) and 11·4 μg RNA polymerase. After incubating for 3 min at 37° C, 1·1 ml. of cold "gradient buffer" was added, and the diluted sample was centrifuged and fractionated exactly as described in Fig. 3. The position of the complex was determined by assaying 200 μl. samples of each fraction for ^{32}P radioactivity, and the peak fractions were pooled. RNA synthesis was assayed in mixtures of 0·25 ml. containing 0·04 M Tris-HCl (pH 7·9) buffer; 12 mM $MgCl_2$; 2·8 mM 2-mercaptoethanol; 0·2 mM each ATP, GTP and CTP; 0·04 mM ^{3}H-UTP (100 Ci/mole); 0·2 mg/ml. bovine serum albumin; 50 μl. of gradient fraction (containing 0·027 μg T4 DNA complexed with RNA polymerase and nascent RNA) and either 0·06 or 0·2 M KCl. Incubation was at 37° C and the amount of ^{3}H-UTP incorporated into acid insoluble material was assayed by the method described in Fig. 1, except that no unlabelled UTP was added during the washes. The background level of unincorporated UTP in these experiments was 20–35 c.p.m. ○, Incorporation in 0·06 M KCl; ▲, incorporation in 0·2 M KCl.

Table 2. TRANSCRIPTION OF T4 AND T5 DNA IN MIXTURES CONTAINING RNA POLYMERASE–NASCENT RNA–T4 DNA COMPLEX AND T5 DNA

Exp.	Addition	KCl concentration (M)	^{3}H-UMP incorporated per 200 μl. (c.p.m.)	Relative composition of RNA (per cent)	
				T4	T5
1	None	0·06	205	90	10
		0·20	208	93	7
		0·06	2,740	41	59
2	RNA polymerase	0·20	3,460	44	56
3	Pure σ-factor	0·06	426	60	40
		0·20	669	50	50

The basic composition of each reaction mixture was the same as that described in Fig. 4. Each mixture of 1·25 ml. contained 0·25 ml. of gradients fraction preparation of complex plus 0·14 μg of T5 DNA and the components listed in the table. For RNA polymerase, 0·5 μg in 5 μl. was added, and for σ-factor (prepared by a modification of the method of Burgess *et al.*[21] and kindly supplied by Mr G. Hager), 0·12 μg in 5 μl. was added. After incubation for 40 min at 37° C, a 200 μl. sample was removed to determine the total incorporation into acid insoluble material and the remaining solution was treated with detergent. After extraction, the RNA was analysed as described in Table 1. It should be noted that the amount of T5 RNA synthesized could not result from the presence of RNA polymerase in the added σ protein. Control assays indicated that less than 5 per cent of the σ protein preparation was RNA polymerase, which should account for no more than 6 per cent of the RNA made in experiment 3.

Experiment 3 of Table 2 also shows that enzyme from the complex can transcribe T5 DNA even in 0·06 M KCl when σ is added. Because there is normally no release of RNA polymerase during synthesis in 0·06 M KCl, this result is surprising, and it suggests either that the complex may contain some enzyme molecules that have not initiated an RNA chain or that there may have been some dissociation of the complex after its isolation. Another possibility, however, is that the added σ-factor may have promoted the release of enzyme molecules, particularly because the amount of σ added may have been in several-fold molar excess over the amount of RNA polymerase present.

Conditions for Release and Reinitiation

These results indicate that during transcription of T4 or T5 DNA *in vitro* in 0·2 M KCl, RNA polymerase is able to terminate the synthesis of RNA chains and to initiate new ones *de novo*. In order for an enzyme molecule to initiate a new RNA molecule, it is presumed that the one synthesized previously has to be released at least from the site of polymerization. Thus the observation presented previously[16] that 0·2 M KCl also stimulates the release of RNA from the enzyme–DNA complex is consistent with this interpretation. Further, because the enzyme also seems to be released from the DNA template during synthesis in 0·2 M KCl, the release of RNA may be linked to the complete dissociation of the complex between nascent RNA, RNA polymerase and DNA.

Reinitiation might not be possible at lower salt concentrations because the RNA cannot be released from the enzyme. Krakow[23], Fuchs *et al.*[11] and Bremer[24] have presented evidence that in restrictive conditions of synthesis RNA polymerase is randomly inactivated by the nascent RNA. In this case the synthesis of many RNA molecules would be terminated prematurely, which might be one explanation for the inability of the enzyme to release the RNA. It is also possible, however, that even if the synthesis of the RNA molecules is not terminated prematurely, release might not occur at low salt concentrations because the binding affinity between enzyme and RNA is too high. In general, the binding affinity of nucleic acids to RNA polymerase decreases as the ionic strength is raised[25]. Consequently, a weaker binding of the nascent RNA to enzyme in 0·2 M KCl may, in one case, reduce the probability that the RNA inactivates the enzyme and, in the other case, facilitate the release of terminated RNA chains.

If termination and release are separate steps, the release step might be much slower. Thus other components that stimulate RNA synthesis by increasing the level of chain initiation—such as polyamines[26] or the combination of ribosomes with the factor C of Revel *et al.*[27]—may act by facilitating the release of RNA chains.

It is possible that ρ or a similar factor present as a contaminant in the enzyme preparation could be responsible for the termination that is observed in these experiments. There is, however, no evidence of a polypeptide contaminant in the enzyme preparation used with electrophoretic properties similar to the polypeptide component of pure ρ factor. Further, because the RNA products are much larger than those found when ρ is present[5,12], it is not likely that this factor itself is a contaminant. Although another factor could still be responsible, termination could actually be an intrinsic property of the reaction catalysed by RNA polymerase. It therefore will be important to determine whether the RNA molecules synthesized in 0·2 M KCl are terminated at specific sites on the template.

I thank Professor A. Tissières for his encouragement and advice; Professor B. Hall and Dr G. Gussin for discussions; Mr G. Hager for the gift of pure sigma protein; Dr G. Cassani for labelled T4 DNA; and Mrs L. Richardson for technical assistance. This work was supported by the Fonds National Suisse de la Recherche Scientifique. I am a postdoctoral fellow of the American Cancer Society.

New Finds at the Swartkrans Australopithecine Site

by

C. K. BRAIN

Transvaal Museum, Pretoria

New discoveries at Swartkrans, in South Africa, an important cave site for the study of the australopithecine stage of human evolution, include a new series of australopithecine remains and an associated stone culture. Recent investigations have clarified the original form of the cave and a study of the accumulations of bones in the cave suggests that the australopithecines who lived there may have been the prey of leopards. In this article, Dr Brain introduces the new discoveries: further reports will follow.

SWARTKRANS, one of the five South African australopithecine cave sites, has produced remains of more than sixty individuals of the large hominid, *Paranthropus robustus*, and is the only cave site where fossils of *Homo* have been found in direct association with those of australopithecines.

The new investigations described here have clarified a number of the important Swartkrans issues. A new series of hominid fossils has been discovered (including two vertebrae which will be described in detail by Dr J. T. Robinson[1]), and it has been possible to associate indisputable stone culture with the hominid remains. The tools have been critically examined by Dr Mary Leakey, who has compared them with an equivalent series from Olduvai Gorge in Tanzania and has found striking similarities with the assemblage from Bed II of that site[2]. In the absence of absolute dating for the Swartkrans fossils, cultural comparisons of this sort assume particular significance. Unexpected new information has come to light on the nature of the second hominid at Swartkrans[3], while a study of the bone accumulation as a whole has led me to conclude that the australopithecine remains, together with many of the other fossils, probably represent food remains of carnivores, especially of leopards.

Swartkrans is situated in the Sterkfontein valley, approximately 8 miles north of Krugersdorp, Transvaal. It was first scientifically investigated in 1948 by the late Dr Robert Broom and by Dr J. T. Robinson, who transferred the Transvaal Museum's operations to the cave from Sterkfontein, on the opposite side of the valley. Excavation of *in situ* breccia continued throughout 1949 and resulted in the recovery of about 3,000 fossils, including numerous *Paranthropus* specimens and remains of a second hominid, named *Telanthropus capensis*[4], but subsequently reclassified as *Homo erectus*[5].

The palaeontological work of 1949 revealed a substantial seam of pure travertine along the north wall of the excavation, and this was exploited commercially by a lime-miner in 1950 and 1951, who left the site in a chaotic state. Robinson excavated the site again in 1952, but the cave was then abandoned until the new investigations, reported here, were started in April 1965.

New Investigations

The new fieldwork at Swartkrans has had two important achievements: first, order has been restored after the chaotic mining episode and excavation of undisturbed breccia is now possible; second, a large and representative sample of 14,000 bone fragments has been recovered.

Our first task was to sort through a substantial dump on the hillside below the cave. Unexpectedly, we found very numerous blocks of fossiliferous breccia, obviously not derived from the 1950–51 mining operations. In fact, more than 200 tons of breccia were recovered from the dump and stockpiled for subsequent attention. Enquiries among old residents of the area revealed[6] that Swartkrans had, in fact, been mined for lime on a previous occasion between 1930 and 1935. The miners had later refilled their excavations with rubble, thereby confusing the situation and leading Robinson[7] to believe that, unlike Sterkfontein, Swartkrans had not been modified by mining before its palaeontological exploration.

After working through the hillside dump, rubble was removed from the excavation and hand-sorted. This work is now almost complete and, after a grid over the excavation area has been erected, selected blocks of breccia from different stratigraphic levels will be removed for detailed comparative study of their fossil contents. It is fortunate that a substantial bank of *in situ* breccia survived the first mining operations and remains today as an inclined surface along the breadth of the cave's south wall. A profile is thus preserved of the whole thickness of the original breccia deposit.

Form of Original Cave

Clearing of the site has clarified the extent of the deposit and form of the original cave, and there will have to be some modification of the original interpretation[8]. In this interpretation, the cave was reconstructed as having comprised two filled chambers, an outer and an inner, with pink unstratified breccia in the former and a brown, stratified deposit in the latter. The two deposits were separated by an unconformable contact, the brown breccia proving to be younger than the pink. After our new investigations, separation into inner and outer chambers remains valid, but study of the east end of the deposit strongly suggests that the outer-cave breccia is not the oldest in the Swartkrans cave and that a still older breccia occupies the eastern extension of the site. This is separated from the normal australopithecine-bearing deposit by a steeply inclined unconformity. Each of the three unconformable contacts between the Swartkrans breccias seems to have resulted from progressive slumping into an underground, lower cavern system. Neither the oldest of the breccias, nor the underlying cavern, has yet been investigated.

In 1958 (ref. 8), the entrance to the outer cave was interpreted as an incline, opening obliquely into the hillside. The walls of the cave can now be seen, however, on all sides except the south-east, where extensive decalcification has occurred. On the evidence of the new exposures, it seems very likely that the original entrance was a precipitous, shaft-like one, perhaps no more than 5 feet in cross-section, linking the cavern with the surface above. Such shaft-like entrances to caverns are a common feature on the undulating dolomite hillsides in the area today. Soil, rock and other debris are funnelled down a shaft of this sort during rain storms, to build up a talus cone in the cavern below the discharge point of the shaft. The discharge point itself is marked by a concentration of rocks and coarse particles in the sediment, while the finer fractions tend to be carried into the further recesses of the cave. It is likely that a vertical shaft discharged in this area, from a hillside depression perhaps 50 feet above it (Fig. 1).

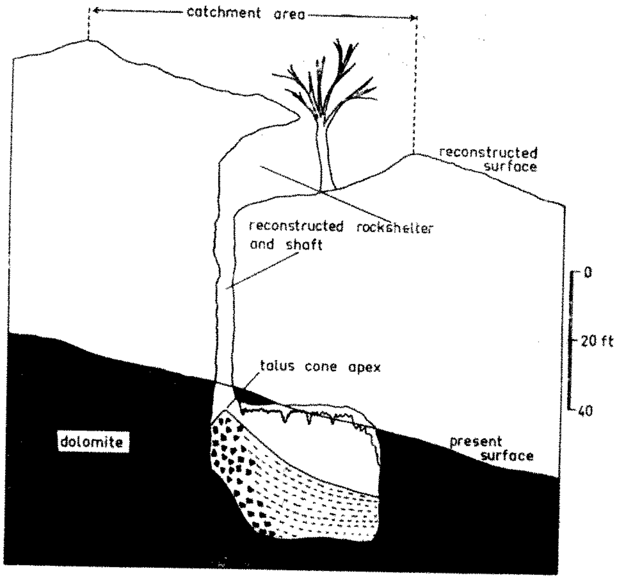

Fig. 1. Diagrammatic N–S section through the Swartkrans hillside. The upper reconstructed part has been removed by erosion since the accumulation of the fossiliferous deposit.

The Swartkrans cave system has developed at the intersection of two fault planes, clearly visible on an aerial photograph. They intersect at an angle of about 87 degrees and it is probable that a large rock-shelter may have existed on the surface in this area, with the shaft descending from it to the underground cavern. If this interpretation of cave form is correct, it is important to realize that the cavern containing the fossiliferous breccia would have been inaccessible to most animals, other than bats and owls. The deposit would, nevertheless, reflect events in the catchment area on the surface during the accumulation period. Relics left by animals or men in the upper rock shelter would ultimately find their way down to the subterranean fossilization site. Stratigraphy in a talus cone is difficult to follow because it is steeply inclined close to the apex, but becomes progressively flatter in those parts of the cave further from the shaft (see Fig. 1). Today, erosion has removed the overlying hillside with its shaft and rock shelter. The original form of these missing parts of the cave system is thus a matter for speculation, but it may be reconstructed on the known geological conformation of the immediate area.

New Hominid Finds

The current fieldwork at Swartkrans has produced a little more than 11,000 bone fragments among which are seventeen recognizable hominid fossils. The hominids, which I shall describe briefly, are all presumed to represent

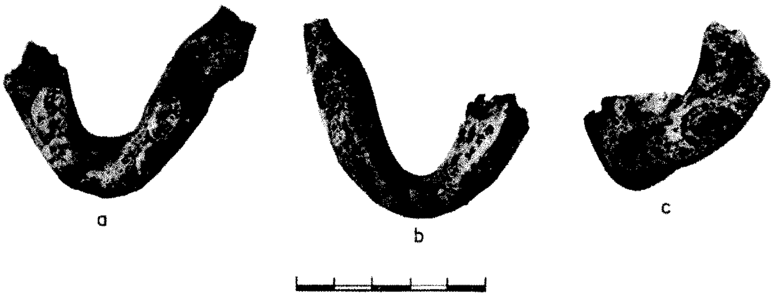

Fig. 2. An infant *Paranthropus* mandible (*SK* 3978) in superior (*a*), inferior (*b*) and lateral view (*c*).

Paranthropus robustus. It has been observed[6] that teeth in two of the mandible fragments (*SK* 1587 and *SK* 1588) were unusually small, with dimensions falling outside the observed range for *Paranthropus* from the site. At the time, it was suggested that these two mandibles may have represented a hominid other than *Paranthropus*, but this now seems unlikely—instead, the hominids probably extend the range of tooth dimensions for the Swartkrans *Paranthropus* sample. Measurements were taken on all teeth which had not suffered damage or undue wear. In the following descriptions mesio-distal length is quoted first, followed by bucco-lingual breadth, in millimetres.

Cranial and Vertebral Remains

SK 3978	Perfectly preserved and undistorted infant mandible lacking rami (see Fig. 2). Left dm$_1$ (10·2 × 7·8 mm) slightly worn, dm$_2$ (13·0 × 10·5 mm) unworn; right dm$_1$ (9·9 × 8·2 mm), dm$_2$ (12·9 × 10·7 mm). Sockets are present for deciduous incisors and canines while the unerupted left M$_1$ is visible in its crypt. Found August 8, 1967.
SK 1585	A natural endocranial cast from a hominid, presumably *Paranthropus* (see Fig. 3). The skull was blasted out by lime miners in the early 1930s and was broken into several pieces before being dumped on the hillside. Two of the surrounding parts of the cranial vault have been recovered, but the face has not yet been found. It is clear that the skull originally came to rest in the cave on its right side and was filled with fine-grained sediment to the level of the top of the foramen magnum. The filling was subsequently hardened with calcium carbonate and is almost completely undistorted. The state of the sutures suggests that the individual was subadult. The endocast has recently been prepared and studied by Dr R. Holloway, who estimates the capacity of the skull to have been 530 cc and whose detailed report will be published elsewhere. Found January 17, 1966.
SK 3981	Two vertebrae, thought to belong to *Paranthropus*; (*a*) a last thoracic, (*b*) a last lumbar. These specimens have been described in detail by Dr J. T. Robinson[1]. Found March 1968.
SK 1587	(*a*) Portion of the left corpus of a mandible with roots of P$_3$, complete P$_4$ (10·6 × 11·6 mm), M$_1$ (14·7 × 12·9 mm); (*b*) isolated right M$_2$ (15·2 × 12·9 mm) complete, from the same block and almost certainly from the same individual. Found July 19, 1966.
SK 1588	Part of a left corpus of a mandible with roots of P$_3$, complete P$_4$ (11·0 × 11·6 mm), M$_1$ (14·0 × 12·3 mm) and root of M$_2$. The specimen is of particular interest because the dimensions of M$_1$ are well below the hitherto observed range for *Paranthropus* from Swartkrans. Found October 6, 1966.
SK 1590	From an adult skull: two palatal fragments (*a*) and (*b*), with an incomplete right I^2, C, P^3 (9·25 × 13·3 mm), P^4 (10·2 × 14·5 mm) and M^1 (13·2 × 14·9 mm), all worn; crushed and distorted mandible (*c*) with parts of premolar and molar teeth. Associated were the head of a femur (*d*) and parts of an innominate bone in poor condition. Found April 13, 1965.
SK 1586	Almost complete adult mandible, severely shattered during fossilization, with right I$_1$, I$_2$, M$_1$ (broken), M$_2$ (15·0 × 14·9 mm) and M$_3$ (16·7 × 15·0 mm); also left I$_1$, M$_1$, M$_2$ (15·0 × 13·8 mm). One of the most robust mandibles from Swartkrans. Found September 1, 1965.
SK 1648	Anterior part of an adult mandible, severely distorted with worn right M$_1$ and M$_2$ (15·7 × 14·5 mm), left M$_1$ (incomplete) and roots of other teeth. Found November 4, 1966.

Isolated Teeth

SK 1593	Right P$_3$ (9·8 × 12·2 mm), well worn, with almost complete root system. Found March 24, 1966.
SK 3974	Right M$_1$ (14·9 × 13·4 mm), perfect crown, slightly worn, without roots. Found July 14, 1967.
SK 1594	Right M$_1$, moderately worn, most of the buccal half including the root. Found September 12, 1966.
SK 3976	Left M$_2$ (17·3 × 16·0 mm), complete and slightly worn. Found May 5, 1967.
SK 14001	Left P^3 (10·5 × 12·8 mm), complete crown but partly damaged root system. Found July 14, 1967.
SK 1589	Right P^4 (11·0 × 14·4 mm), complete crown of an unerupted tooth. Found October 14, 1966.
SK 3977	Right M^3 (15·5 × 17·9 mm), slightly worn. Found May 5, 1967.
SK 3975	Left M^3 (14·6 × 16·7 mm), slightly worn. Found July 28, 1967.
SK 14000	Upper molar broken through middle, showing pulp cavity. Found November 11, 1967.

The following eight hominid fossils were recently found in blocks of breccia brought back to the Transvaal Museum during the Broom/Robinson operations at Swartkrans. They came to light when the breccia was processed in acetic acid. All are assigned to *Paranthropus robustus*.

SK 1596	Isolated upper canine, heavily worn, with almost complete root system.
SK 1591	Isolated left M^1 (13·0 × 14·4 mm), fairly worn with part of the root system.
SK 1524	Isolated left M^3; most of the mesial portion of an unerupted and incompletely developed crown.
SK 1514	Mandibular fragment in very poor condition with roots of two molars and crown of one.
SK 1595	Fragment of a maxilla with slightly worn left dm^2 (11·5 × 12·4 mm) and pieces of erupting anterior teeth.
SK 1512	Palatal fragment with roots of several cheek teeth and part of a premolar.
SK 1592	Palatal fragment with broken right P^4, M^1, M^2 and part of M^3; also the root of one of the anterior teeth.
SK 14003	Part of a crushed skull with left M^1 (incomplete), part of right M^1, M^2 and complete M^3 (15·0 × 16·2 mm).

Stone Culture

The presence of a stone culture at Swartkrans was first suspected in 1956 when several quartzite tools, encased in breccia, were found there[8]. Recent examination of breccia blocks, blasted from the outer cave by the lime miners, has led to further recovery of occasional pieces of rock, foreign to the immediate vicinity of the cave and, in some cases, artificially worked. To date, 195 foreign stones have been found, fifty-one of which show signs of artificial fracture. The whole collection has been studied in detail by Miss S. M. Johnston, who has very kindly made her results available to me (see Table 1).

Table 1

Rock type	No. of pieces	Per cent of total foreign stones	Average wt (g)	No. of waterworn pieces	No. of worked pieces
Quartzite	148	75·9	507	87	33
Vein quartz	36	18·5	226	3	8
Diabase	6	3·1	450	1	5
Other	5	2·5	166	0	5
	195	100·0	337 (overall average)	91	51

The most numerous rock type present, quartzite, has its origin on the Witwatersrand escarpment a few miles to the south of Swartkrans; vein quartz occurs sporadically in the dolomite formation, while the closest outcrop of diabase is about 1 mile south-east of the cave, on the opposite side of the valley. Although fifty-one of the stones showed some signs of artificial fracture, only thirty of them could be termed artefacts and these have been studied and described in detail by Dr Mary Leakey[2]. All the tools, with the exception of the two diabase bifaces and one quartzite chopper, have edges so sharp that they were

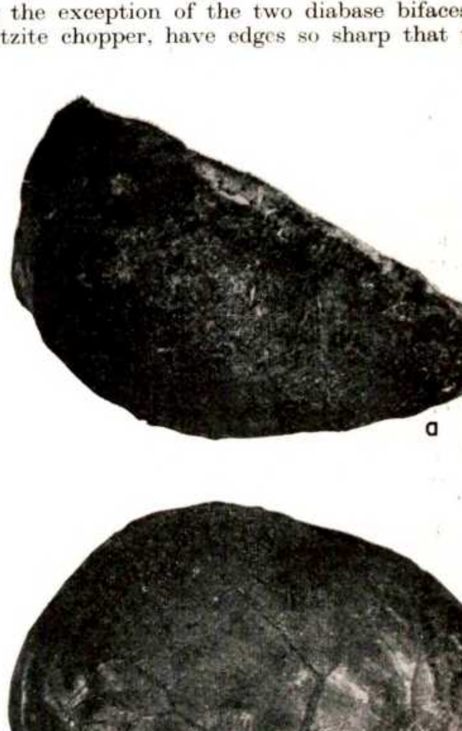

Fig. 3. A natural endocranial cast (*SK* 1585) from a Swartkrans hominid in superior (*a*) and right lateral view (*b*).

clearly made close to the cave entrance shortly before their inclusion in the deposit. The diabase tools both have weathered cortices, but it is known that diabase weathers while it is enclosed in a damp breccia deposit. The one quartzite chopper had been waterworn after manufacture, but before fossilization. It was originally assumed that all the foreign stones must have been brought to Swartkrans by human (or proto-human) agency; it now seems likely, however, that an old river gravel may have existed on the Swartkrans hillside when the cave deposit was accumulating and that some of the pebbles found their way naturally into the cavern, together with the soil and debris which were washed down into it. Tools that were made at the cave entrance were presumably fashioned on pebbles which happened to be in the immediate vicinity.

In view of the possibility that the Swartkrans foreign stones may have originated in a river gravel, a detailed study of contemporary gravels in the area has been made. The cave is situated 700 feet from the present course of the Blaaubank River, but this stream does not normally flow except after heavy rain. Sparse river gravels occur along the sides of the valley and, from three separate localities within 1·5 miles of the cave, Miss Johnston was able to collect a sample of 152 foreign stones for comparison with the Swartkrans specimens. The results of this comparison indicate that the Swartkrans foreign stones are very similar to those associated with the stream course in the vicinity of the cave. Waterworn quartzite pebbles proved to be slightly more abundant in the Swartkrans sample than in the gravel, but the percentage abundance of vein quartz pieces did not differ significantly between the two. Weights of the pieces in the two samples were found to be almost exactly comparable. The stones in the gravel sample also did not differ significantly in shape from those in the Swartkrans collection.

On the basis of this study, it seems that the foreign stones at Swartkrans were almost certainly derived from an old gravel, associated with the stream course. Artificial transportation need not be invoked because, if the gravel lay within the catchment area of the cave entrance, it would have been washed into the underground cavern together with other surface debris. The stone tools are nevertheless of special significance, because they are indicative of sporadic hominid activity near the cave entrance during the Swartkrans accumulation period. Two different hominids are known at the site, *Homo erectus* and *Paranthropus robustus*, but it is not certain which was responsible for the stone tools. Three of the stones in the collection show evidence of heat-spalding, suggesting that they had been in a fire shortly before inclusion in the deposit. On this slender, but interesting, evidence it would be premature to suggest that the Swartkrans hominids had mastered the deliberate use of fire. Grass fires, started by lightning, are a recurrent feature of the Transvaal highveld and, when sweeping through a leaf-strewn rock shelter, can generate a good deal of heat. Nothing resembling a bone tool has yet been found at Swartkrans, in spite of examination of every fragment in the collection.

Interpretation of the Bone Accumulation

In the interpretation of any bone accumulation preserved in a cave deposit, the original form of the cave is of crucial significance because it is this that determines the kinds of animals likely to have made use of the site. As already described, Swartkrans seems to have consisted of a hillside rock-shelter, probably supporting several large trees, but enclosing a vertical shaft which descended to an underground cavern, in which the fossiliferous deposit accumulated (Fig. 1). The latter cavern was simply a receptacle into which surface-derived debris was funnelled, while the nature of the rock-shelter on the surface was presumably such that it is likely to have been used by a wide variety of animals, as well as primitive man. The sample of 14,000 fossil bone fragments currently being analysed comes from a thickness of deposit which probably took several thousand years to accumulate. At Swartkrans we are not dealing with an impressive concentration of bones, but rather with a more or less even scatter throughout the calcified soil which originally filled the cave. It is probably not necessary to account for the collection of more than about ten bones per year and these could have found their way into the cave in a variety of ways. Some of the possibilities will be considered.

It is, for instance, known that many animals, when injured or sick, will retreat into caves to die. If unmolested, complete skeletons or scattered undamaged bones can be expected to result. Nothing approaching a complete or undamaged skeleton has been found in the Swartkrans breccia and natural deaths are not thought to have been important. The same is true of artificial burials which are unlikely to have occurred during the australopithecine period.

A recent study of important factors in Southern African bone accumulations (my work, in preparation) has shown that porcupines are of the greatest significance as collectors of bones in caves. They are known to horde large numbers of bones in their lairs, but all their collections so far studied have been characterized by a high percentage of gnawed bones on which the marks of the rodents' incisors are unmistakable. The final figure for the percentage of porcupine-gnawed bones in the Swartkrans sample has yet to be determined, but it will probably be less than 5. It is therefore concluded that, although porcupines almost certainly contributed to the Swartkrans bone collection, their influence was small.

Second to porcupines, primitive men rated high in importance as collectors of bone fragments in caves during the South African Stone Age. A detailed comparative study of human bony food remains from various Southern African caves has led me to conclude that these accumulations are characterized by the extreme fragmentation of the bones (my work, in preparation). A high percentage abundance of long-bone flakes and unrecognizable fragments is indicative of human activity, in which the bones are broken with stone tools for the extraction of marrow. As already mentioned, fifty-one stone artefacts have been recovered from the Swartkrans breccia, many of them chopping tools suited to the breaking of bones for the extraction of marrow. Bone flakes and fragments do occur in the accumulation but they are not abundant, suggesting that human feeding activity occurred sporadically within the catchment area of the Swartkrans cave but that this was not of major importance in the building up of the bone collection.

Carnivore Activity

The overall impression given by the Swartkrans bones is that they represent carnivore food remains; they come predominantly from antelope, baboons, australopithecines, hyraxes, and so forth, and are usually fragmentary, often showing damage apparently caused by carnivore teeth. Antelope are characteristically represented by a wide variety of damaged skeletal parts, but remains of many other animals are essentially cranial in origin, with very little else. The Swartkrans breccia has yielded an interesting series of carnivores, some of which were almost certainly involved in the collection of bones at the site. Forms identified to date are as follows (taxonomy according to Ewer[9–11]): hyaenids: *Crocuta crocuta venustula* (spotted hyaena), *Hyaena brunnea dispar* (brown hyaena), *Lycyaena silbergi nitidula*, *Leecyaena forfex*; sabre-toothed cats: *Therailurus* sp., *Megantereon* sp., *Nimravidae indet.*; felids: *Panthera pardus incurva* (leopard), *Panthera* sp. (lion); canids: *Canis mesomelas* (jackal), *Vulpes* sp. (fox); viverrids: *Cynictis penicillata* (mongoose).

Both the *Crocuta* and the *Hyaena* are regarded as early representatives of the extant spotted and brown hyaenas, while *Lycyaena* and *Leecyaena* represent extinct genera, the former showing characteristics which have been interpreted as "reflecting a secondary adaptation to a more predacious, less scavenging habit—a change presumably brought about under the selective pressure of competition with more efficient scavengers"[11]. *Leecyaena* is characterized by anterior cheek teeth resembling those of an advanced *Hyaena* and could possibly be ancestral to *H. bellax*, described from Kromdraai.

The three different sabre-toothed cats are represented by rather fragmentary material. Ewer has pointed out that, as a result of highly efficient carnassial shear, these carnivores were adapted to the slicing of meat and had premolars so reduced that they "must have been unable to deal with more than the very smallest bones"[11]. The conclusion that sabre-toothed cats left the skeletons of their prey almost intact has important implications, in that a niche was thus created for various species of hyaena, not necessarily capable of crushing the more resistant bones. Hyaenas like *Lycyaena* and *Leecyaena* may have owed their livelihood to the remains left by the abundant sabre-tooths of the day. As Ewer[11] has remarked: "The period of hyaena abundance in the Lower Pleistocene is thus also a period of abundant sabre-tooths and the disappearance of the latter during the Middle Pleistocene corresponds with the shrinkage of the hyaenid fauna to those few species which have succeeded in surviving today, in association with modern Felinae". Regrettably little is known about the behaviour of South African sabre-tooths and it is uncertain whether they were dominant to the associated hyaenas or whether they were forced to retreat with their prey into the seclusion of caves or trees. If so, it is likely that they would have contributed bones to the Swartkrans accumulation and that some of these may have been modified by the less competent bone-crushing hyaenas, such as *Lycyaena* and *Leecyaena* before fossilization. (It is unlikely that the bones found today as fossils were ever thoroughly worked over by spotted or brown hyaenas; if they had, few would have remained to become fossilized.) Sabre-tooth involvement at Swartkrans can neither be demonstrated nor disproved, but it is very likely that the bone accumulation was added to by these cats and that the remains were modified by primitive hyaenas before being fossilized.

The Role of Leopards

Leopards are well represented among the Swartkrans fossils, where remains of at least thirteen individuals have been found. As *Panthera pardus incurva*[10], they differ from the living leopard on the subspecific level only, with an indication that the fossil form may have been a little smaller than its contemporary counterpart. It has already been noted that the presence of sabre-toothed cats could have been important to the survival of primitive hyaenas; in the same way, the direct association of leopards and spotted hyaenas was probably a crucial factor in the building up of the Swartkrans bone accumulation.

Where leopards share their hunting area with spotted hyaenas, it is well known that, if they are to retain their prey, they are obliged to feed in places inaccessible to the scavengers. I recently studied fifteen leopard kills in the Kruger National Park. Spotted hyaenas were attracted to all these kills, but in twelve cases the leopards took their prey into trees sufficiently promptly to avoid interference. In three they were not quick enough and, as a result, lost their prey to the hyaenas.

In a woodland habitat, leopards have little difficulty in finding suitable trees for storage of their prey, but the situation in open country is rather different. Swartkrans is situated today on the open highveld, an area of undulating grassland, almost devoid of trees except along the watercourses. Study of the composition of the antelope fauna from the Swartkrans deposit suggests that, during the infilling of the cave, open grassland conditions prevailed as they do today, the fossil fauna being dominated by gregarious plains-living species such as springbuck, gazelles and alcelaphines of various sizes. Leopards hunting on the open highveld have to make use of suitable cliffs, caves and the few available trees for the protection of their prey. An interesting and highly significant correlation is found to exist between the occurrence of large trees and caves in the dolomitic areas of the Transvaal highveld. In this gently undulating countryside, caves are typically of the shaft or sinkhole variety, with depressions surrounding their entrances. Whereas the hillsides themselves are devoid of trees, the cave entrances characteristically support several large stinkwood (*Celtis kraussiana*) or wild fig (*Ficus* spp.) trees, which flourish there as a result of protection afforded to them from frost and fire. Leopards are thus inevitably attracted to the dolomitic caves as places of safe retreat, while the associated trees are invaluable for the storage of their prey. Food remains of leopards are consequently introduced into the catchment areas of the cave entrances and some will ultimately find their way down to the subterranean fossilization sites. Assuming that the Swartkrans deposit accumulated during a period of perhaps 20,000 years, it would be surprising if the cave and its associated trees had not been used on innumerable occasions by leopards as a feeding place and lair. The cave was inhabited throughout its life by owls whose regurgitated pellets have built up a concentration of microfaunal remains in the deposit, to give a remarkably complete picture of the animals hunted by the owls in the vicinity of the cave. In the same way, the larger faunal remains at Swartkrans are very likely to contain evidence of the range of animals hunted by leopards in this particular area.

Studies on living leopards have made it clear that the nature of their food remains is considerably influenced by the presence or absence of hyaenas (my work, in preparation). In the Kruger Park study area, where the leopards are constantly harried by hyaenas, they were found to do considerable damage to the skeletons of their prey (largely impala). They would typically return to the carcass in the tree during a period of 3–4 days, by which time most of the body had been consumed. The head and lower leg segments would invariably be left, usually hanging on strips of skin, but the rest of the skeleton generally disappeared. As part of this investigation, leopards were also studied in South West Africa, in an area where no hyaenas or other significant scavengers occur. Here the pattern of leopard food remains was completely different. The leopards made no attempt to drag their prey into inaccessible places, except where the kill had been made close to human habitation. They typically ate where they killed and did comparatively little damage to the prey skeletons, eating only a small quantity of meat before moving on to make another kill a few days later. It is consequently impossible to define the characteristics of "typical" leopard food remains. Their nature will depend on the availability of food and the pressure applied to the leopards by dominant scavengers such as spotted hyaenas.

The greater part of the Swartkrans bone accumulation shows characteristics consistent with those of leopard food remains, and suggests a situation where the leopards had been regularly harried by hyaenas. There are, however, several features of the bone collection which require special explanation. These involve the disproportions in the skeletal parts preserved. In the case of bovid skeletons, it has already been established that certain parts are more resistant to destruction than others and it is possible to predict which parts are likely to survive any particular treatment[12]. At Swartkrans, for instance, bovid distal humeri are almost five times as common as proximal ones. Such a disproportion is to be expected and means simply that the carnivore involved was able to chew away the relatively fragile proximal end of the humerus, but had trouble with the resistant distal one. The difficulty is encountered when we compare the recognizable remains of primate skeletons (such as of baboons and australopithecines) with those of bovids. The latter are typically represented by a wide variety of damaged skeletal parts, while the former are largely cranial in origin with very little else. In fact, the Swartkrans *Paranthropus* sample consists of 190 separate pieces, representing a minimum of at least sixty individuals. Of these fossils, only eleven are post-cranial bones.

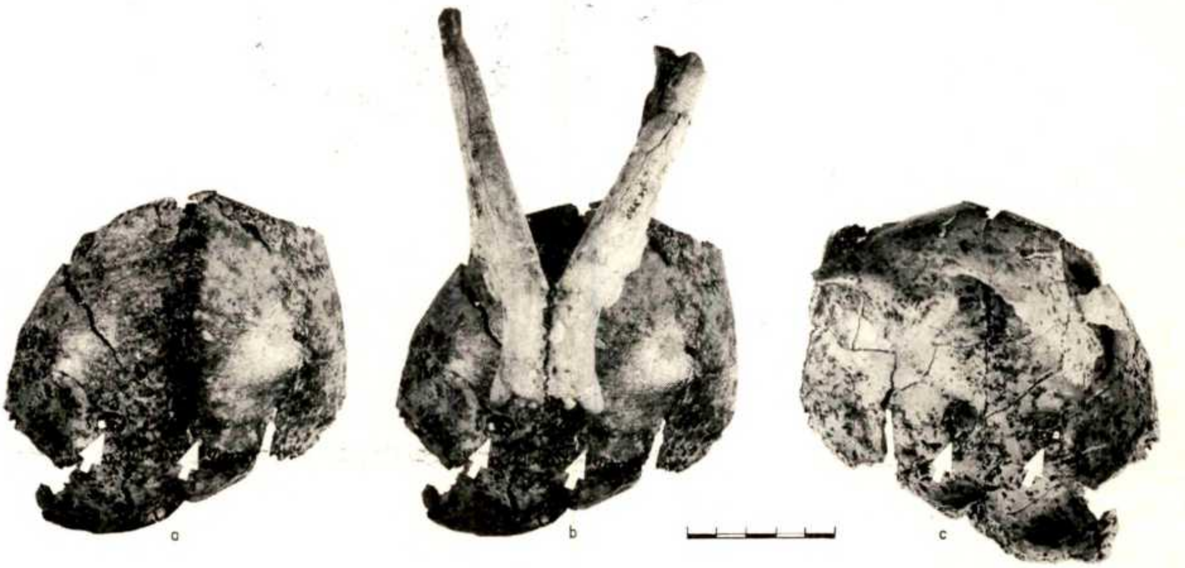

Fig. 4. Part of a hominid skull (*SK* 54) from Swartkrans showing holes thought to have been made by canine teeth. (*a*) Posterior view of left and right parietals and part of the occipital (arrows indicate position of holes on either side of lambda); (*b*) same view as in (*a*) to show how spacing of holes is matched by that of canine tips in the type mandible of the Swartkrans leopard; (*c*) internal view showing flakes of bone lifted when the parietals were pierced.

The probable reasons for this remarkable state of affairs have been suggested by a series of feeding experiments with cheetahs that I have recently carried out. A natural group of five wild cheetahs was caught on Valencia Ranch in South West Africa and maintained in a large semi-natural enclosure there, through the cooperation of Mr A. F. Port. Within a short period the cheetahs tolerated human observers and fed readily on the animals provided. Previous observations had indicated that cheetah damage to bovid skeletons, from animals in the 50–150 pound range, was minimal. It was restricted to fragile parts such as ribs, vertebral processes and scapulae. These observations were confirmed in the feeding experiments and, when the cheetahs had fed on a springbuck for instance, almost the whole skeleton remained. When a baboon of equivalent weight was eaten, however, a very different result was obtained. The cheetahs were able to consume the whole of the vertebral column, the hands and feet, as well as to do appreciable damage to the ends of the limb bones. The reason for this difference clearly lies in the fact that the construction of a baboon skeleton is considerably less robust than that of a bovid of equivalent live weight. The baboon vertebral column is fragile enough to be consumed, while the hands and feet are found to be fleshy and palatable.

It is not suggested that cheetahs were involved in the Swartkrans situation: they are simply amenable experimental animals. Nevertheless, conclusions drawn from them on the comparative robusticity of prey skeletons will be equally applicable to leopards, which are known to be capable of doing far more extensive damage to the skeletons of their prey. A leopard is potentially capable of eating virtually a whole baboon, with the exception of the skull, which is invariably left. Conclusions drawn about baboons will be equally applicable to hominids, built on the generalized primate pattern, provided that their larger size is taken into account. One of the reasons for the fact that so few primate limb bones have been recognized in the Swartkrans accumulation may lie in the fact that the diagnostic ends of such bones are typically chewed off by leopards, with the result that damaged and undiagnostic shaft pieces remain. Many of the indeterminate bone fragments at Swartkrans could well be of australopithecine origin.

One of the australopithecine skull pieces from Swartkrans appears to bear direct evidence of leopard activity. The specimen, *SK* 54, consists of much of the calvaria of a subadult hominid thought to have been a *Paranthropus*. It was found at the site in 1949 and subsequently prepared by Dr Robinson in Wisconsin, using the acetic acid technique. As shown in Fig. 4, the fossil consists of left and right parietal bones, part of the occipital and much of the frontal. The frontal has been distorted downwards, approximately across the width of the coronal suture, while the whole specimen has been slightly flattened by pressure in the deposit. From a comparison of the size of the parietal bones with those of other Swartkrans specimens, it is estimated that the endocranial capacity of this skull was approximately 500 cm^3. The two holes in the back of the skull, one in each parietal bone, close to lambda (see Fig. 4), are particularly interesting. Each is slightly elongated in a lateral direction and is approximately 6 mm in its shortest diameter. It is clear that the holes were made by two pointed objects, whose tips diverged slightly. On the internal surface of the parietals, flakes of bone have been lifted in a characteristic manner, suggesting that the bone was fresh and pliable when the injury was inflicted. If the two holes were made simultaneously, the points of the two sharp objects responsible must have been approximately 33 mm apart.

In a recent survey of the evidence for intrahuman killing in the Pleistocene, Roper[13] mentions this particular specimen and quotes Ardrey's argument[14] that the holes indicate that the australopithecine was struck twice on the back of the head with a pointed object. I believe that it is more likely that the two holes were made simultaneously by the canine teeth of a carnivore spaced about 33 mm apart. The question remains as to which species may have been involved and in what position the australopithecine's head could have been held when the damage was inflicted.

The Swartkrans fossils include remains of carnivores ranging in size from lion to mongoose. In many cases they represent forms closely related to living species so that, although the fossil material is fragmentary, modern skulls may be used to give an indication of typical canine spacings. Making use of the collection in the Transvaal Museum, distances between upper and lower canine tips have been measured on skulls of seven extant species (Table 2).

Results are plotted in Fig. 5, where the estimated ranges for some of the extinct species are also shown. On the basis of rather inadequate material, it is concluded that the known Swartkrans sabre-toothed cats had canine spacings intermediate between those of lions and spotted hyaenas. The type skull of *Leecyaena forfex* (*SK* 314) is comparable in size with the skull of a *Crocuta* and had upper canines spaced about 46 mm apart. Specimens of *Lycyaena* from Swartkrans appear to have had spacings intermediate between those of the living hyaenas and leopards.

It will be seen that the figure of 33 mm, representing the distance between the holes in the fossil skull, falls well within the leopard range and coincides with the mean figure for lower canine spacings in the female skulls measured. It must be remembered, however, that the fossil leopards seem to have been a fraction smaller than their living counterparts. It can naturally not be proved that a leopard (or any other specific carnivore) was responsible for the damage to the fossil skull, but, considering the various lines of evidence from Swartkrans, it is very probable that leopard canines did, in fact, produce the holes. Similar holes in the skulls of baboons eaten by leopards in the Suswa caves of Kenya have been reported by Simons[15]. A leopard typically kills its prey with a firm grip across the throat but, when subsequently dragging a dead animal to a protected feeding place, will often grip the head in its jaws. Fig. 6 shows how this may have been done in the case of the Swartkrans *Paranthropus* child. Under the weight of the child's body, the leopard's lower canines may have penetrated the rather thin parietal bones, while the upper canines were firmly embedded in the face.

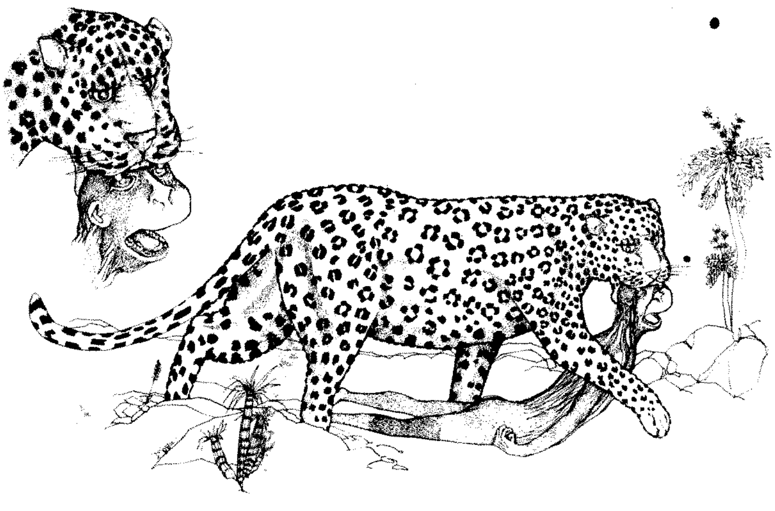

Fig. 6. Reconstruction showing how the observed damage to the skull of a Swartkrans *Paranthropus* child could have been caused by a leopard. The leopard's lower canines are thought to have penetrated the parietals of the dead child while it was being dragged to a feeding place.

Table 2. DISTANCES BETWEEN UPPER AND LOWER CANINE TIPS ON SKULLS OF SEVEN CARNIVORES

Carnivore	*n*	Upper canine spacing, mm Range	Upper canine spacing, mm Mean	Lower canine spacing, mm Range	Lower canine spacing, mm Mean
Lion, *Panthera leo*	17	60–81	67	53–69	59
Brown hyaena, *H. brunnea*	17	44–57	52	43–57	52
Spotted hyaena, *Crocuta crocuta*	8	49–57	54	42–54	46
Male leopard, *Panthera pardus*	10	33–47	39	31–41	36
Female leopard, *Panthera pardus*	14	33–42	38	30–38	33
Jackal, *Canis mesomelas*	20	21–28	25	21–26	23
Fox, *Vulpes chama*	11	14–19	16	11–16	13
Mongoose, *Cynictis penicillata*	25	10–13	11	9–13	10

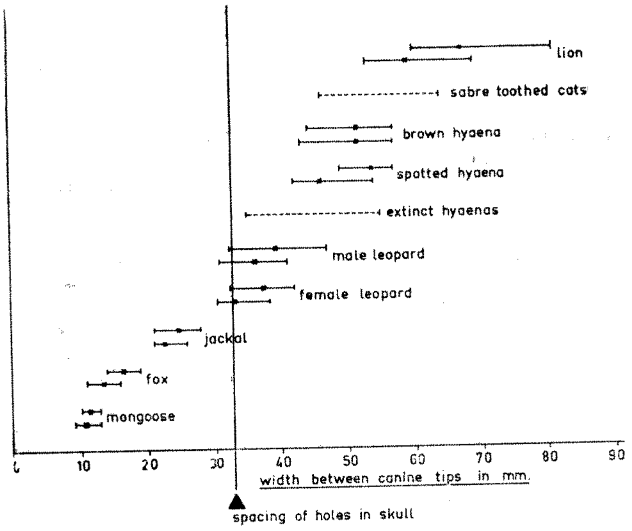

Fig. 5. Canine spacings in some South African carnivores. Observed ranges and means are plotted for upper and lower teeth while estimated ranges for Swartkrans sabre-tooths and extinct hyaenas are included.

The evidence presented here suggests that *Paranthropus* individuals were preyed upon by leopards in the same way as were baboons, hyraxes and antelope. Leopard predation on humans still occurs today; such predation would presumably have been much more prevalent at a stage of human evolution when australopithecines were neither physically formidable nor protected by the weapons of an advanced technology.

The renewed work at Swartkrans would not have been possible without the support of the Wenner-Gren Foundation for Anthropological Research; in particular I wish to thank Mrs L. Osmundsen for her interest in the project. I also thank the trustees of the Transvaal Museum and the South African CSIR for their support; the University of the Witwatersrand, present owners of Swartkrans, for help and permission to continue research there; Professor P. V. Tobias and Professor F. Clark Howell for helpful discussions; the South African National Parks Board for research facilities in the National Parks; Mr and Mrs A. F. Port for the opportunity to study living carnivores on Valencia Ranch, South West Africa; and my wife, Mr A. C. Kemp and Mrs E. A. Voigt for their help with the research.

Osculatory Packing of Finite Areas with Circles

by
H. H. KAUSCH-BLECKEN VON SCHMELING*
N. W. TSCHOEGL
California Institute of Technology,
Pasadena, California 91109

Osculatory packing of a finite area by circles requires that any uncovered area or interstice be filled always with the largest possible non-overlapping circle. The strength of this requirement makes it possible to derive a general analytic expression that approximates closely to the distributions of radii calculated for various sets of boundary conditions.

THE problem of covering a finite area with a given set of circles has received frequent attention. In particular the maximum packing fraction, that is, the ratio of the covered area to the total area, has been determined for a variety of boundary conditions[1-8]. The densest packing of non-overlapping uniform circles is the hexagonal lattice packing[1,2] with a packing fraction of $\varphi = \pi/\sqrt{12} = 0{\cdot}9069$.

The biggest packing fraction with bimodal circle size distributions is obtained if the larger circles, of radius R_1, form a hexagonal lattice, the interstices of which are filled by a large number of smaller circles with radius R_2. If the smaller circles within each interstice are also packed hexagonally, then in the limit that $R_2 \ll R_1$, the packing fraction of all circles will be given by $\varphi_2 = 1-(1-0{\cdot}9069)^2$. The limiting packing fraction for k different circle sizes, with each size packed hexagonally, is

$$\varphi_k = 1-(1-0{\cdot}9069)^k \tag{1}$$

Clearly φ_k approaches unity for large values of k. It follows immediately from the condition $R_k \ll R_{k-1}$ and from the size of the interstice ($0{\cdot}323\ R_{k-1}^2$ in a hexagonal lattice) that the number of smaller circles necessary to cover an interstice is very large. Evidently the condition $R_1 \gg R_2 \gg \ldots R_k$ minimizes the number of different circle sizes required to cover a given area to a given extent. We present here an approximate solution to the problem of minimizing the number of circles without regard to the number of different circle sizes.

The maximal covering of a finite area by a minimum number of non-overlapping circles will be called optimal covering. Optimal covering requires a distribution of circle sizes which, when truncated at any arbitrary lower limit, will always yield a larger packing fraction than any other distribution with the same number of circles, truncated at the same limit. Following Melzak[7], we shall call a distribution osculatory if any available area is always covered by the largest possible circle. If the original area to be covered is either a triangle or a tricuspid area, as shown in Fig. 1, then the first circle to be placed must touch the boundaries of the area at exactly three points. Further, all circles placed subsequently in the remaining spaces must touch the boundaries or neighbouring circles at exactly three points. In the limit of an infinitely small lower bound of the distribution, optimal and osculatory packing lead to the same distribution of circle sizes. Our investigation of the osculatory packing of circles is a first attempt to learn about optimal distributions of particle sizes with various boundary conditions and modes of packing.

Osculatory Packing of Finite Areas

The relationship between the radii of four osculating circles has been described by Soddy[9] in a poem that appeared in *Nature*. In a more prosaic formulation, and solved with respect to R_4, this relation is

$$R_4 = \frac{R_1R_2R_3}{R_1R_2+R_2R_3+R_1R_3+2\sqrt{R_1R_2R_3(R_1+R_2+R_3)}} \tag{2}$$

As shown in Fig. 1, three new interstices are created by placing the circle with radius R_4 into the tricuspid interstice formed by the three circles with radii R_1 to R_3. The radius of the touching circle placed into any of the new tricuspid interstices can be calculated from equation (2) by making the proper substitutions of radii. The radii of all subsequent smaller circles can be calculated similarly. (From Lemma 7 of ref. 8, the square rooting can be avoided after the first stage.) We call the circles with radii R_1 to R_3 the parent generation, and the circle with radius R_4 the zeroth generation. Because the number of circles per generation increases by a factor of 3 in all further generations, we use K subscripts to denote a radius of the Kth generation and allow each subscript to assume the values 1, 2 or 3. The radii of the circles of the first generation are thus denoted by r_i ($i = 1,2,3$), those of the second generation by r_{ij} ($i, j = 1,2,3$), and so on. The distribution of circle radii within any one generation is determined

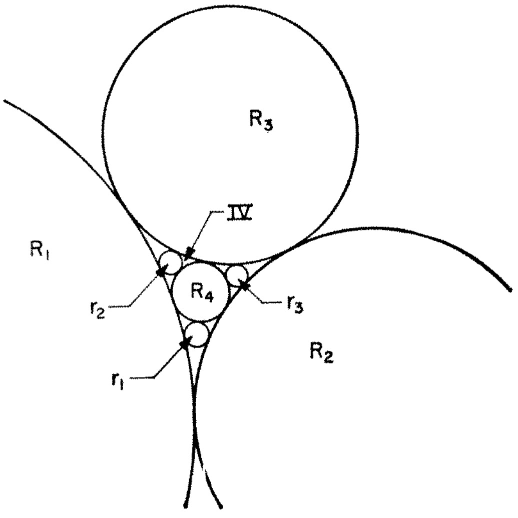

Fig. 1. Tricuspid interstices.

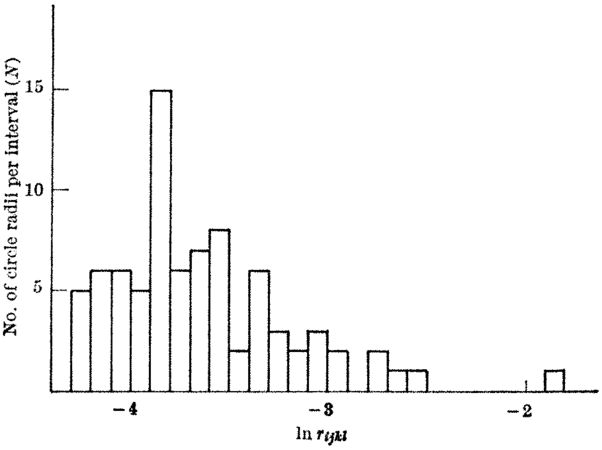

Fig. 3. Distribution of fourth order circle radii obtained by optimal filling of subcell of equilateral triangle.

largely by the order of the generation. Using equation (2), the first generation radii r_i can be computed from R_j, R_k and R_4. Then the second generation radii r_{ij} can be obtained, and so forth. We shall always arrange the parent radii so that $R_1 \geq R_2 \geq R_3$.

Fig. 2 shows the distribution of the radii of the fourth generation of circles filling the tricuspid area (see Fig. 1) formed by three parent circles the radii of which decrease by the constant factor 0·3460 so that $R_1 : R_2 : R_3 = 1 : 0{\cdot}3460 : 0{\cdot}1197$. The constant factor 0·3460 results from the requirement that $R_1/R_2 = R_2/R_3 = R_3/R_4$. To define a convenient reference point for the ratios of radii, R_4 was arbitrarily taken as unity. The distribution following from this particular choice of boundary conditions has features which facilitate the derivation of the analytic expression to be obtained later. Fig. 3 shows a similar plot for the boundary conditions illustrated by area II in Fig. 4. The parent circles were chosen as the circle inscribed in an equilateral triangle (R_2), the circle obtained by filling the interstice thus formed (R_3), and the side of the triangle which may be regarded as the third parent circle (R_1) having an infinite radius. Because the triangle is equilateral, $R_2/R_3 = 1/3$. The radii of the zeroth, first and any subsequent generation can be calculated from equation (2) by letting the parent radius equal infinity when the new circle touches the straight line. Figs. 2 and 3 show that the two distributions do not differ widely in spite of the difference in the boundary conditions.

The essential independence of the distributions of circle radii from the boundary conditions is seen more clearly when one examines the behaviour of the first and second movements of the distributions. We denote any radius of a circle of the Kth generation by $r(_K)$ and the first moment of the logarithms of all circle radii within the Kth generation by $\langle \ln r_{(K)} \rangle$. The first moments were calculated as a function of K for the six different boundary conditions listed in Table 1 together with the radii of the respective parent circles. The radius R_4 of the zeroth generation was taken to be unity in all cases.

Table 1. RADII OF PARENT CIRCLES FOR BOUNDARY CONDITIONS OF CIRCLE SIZE DISTRIBUTIONS

	Boundary condition	R_1	R_2	R_3	R_4
I	Ideal tricuspid interstice	24·14	8·35	2·89	1·0
II	Subcell of equilateral triangle	∞	7·47	2·49	1·0
III	Uniform tricuspid interstice	6·46	6·46	6·46	1·0
IV	Subcell of uniform tricuspid interstice	45·75	7·07	2·87	1·0
V	Irregular tricuspid interstice	12·58	6·15	4·31	1·0
VI	Equilateral triangle	∞	∞	∞	1·0

Boundary condition I, referred to as ideal tricuspid, and condition II, subcell of equilateral triangle, have already been discussed. They yield the distributions of fourth generation circle radii shown in Figs. 2 and 3 respectively. Condition III is given by the uniform tricuspid area formed from three circles of equal radii ($R_1 = R_2 = R_3$). Condition IV is the subcell of the uniform tricuspid formed from one circle each of the parent, zeroth and first order generation of the uniform tricuspid area III. Such a subcell of an irregular tricuspid is shown as area IV in Fig. 1. Condition IV is derived from a uniform tricuspid interstice. Condition V is the irregular tricuspid area formed by three parent circles with arbitrarily chosen radii. Finally, boundary condition VI is represented by an equilateral triangle the side of which may be regarded as circles of infinite radii. Here the zeroth generation circle with radius R_4 is the circle inscribed in the triangle, the sides of which must equal $2\sqrt{3} = 3{\cdot}46$ to give $R_4 = 1$.

In Fig. 5 $\langle \ln r(_K) \rangle$ is plotted against K for the six boundary conditions. For the circle radii distributions derived from the boundary conditions I–V the mean, $\langle \ln r(_K) \rangle$, is a linear function of K for $K > 0$ with slope

$$\frac{\mathrm{d}M_1(K)}{\mathrm{d}K} = \frac{\mathrm{d}\langle \ln r_{(K)} \rangle}{\mathrm{d}K} = -0{\cdot}91 \qquad (3)$$

The curve for the triangular area VI differs slightly but has the same slope for $K \geq 2$.

The constancy of the decrease of the average logarithmic circle radius with K is an interesting feature and warrants a little more scrutiny. The constancy is a consequence of the property of equation (2) to yield values of R_4/R_3 in a very narrow range for widely varying ratios of R_2/R_1 and R_3/R_2. If we let

$$\ln y(K) = \langle \ln r_{(K)} \rangle - \langle \ln r_{(K-1)} \rangle \qquad (4)$$

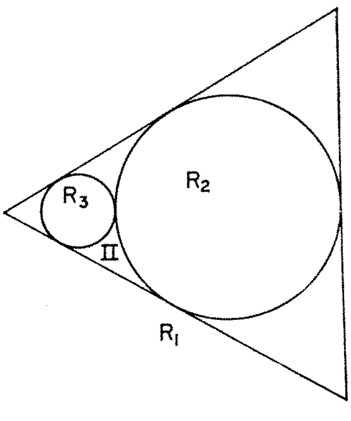

Fig. 4. Subcell of equilateral triangle.

then the ratio R_4/R_3 can be denoted by $y(0)$. In Fig. 6 the functions $y(0)$ and $y(1)$ are plotted against R_3/R_2 with R_2/R_1 as parameter. With R_3/R_2 and R_2/R_1 independently assuming values between 0 and 1, all possible shapes of tricuspid areas can be represented. It is seen that $y(0)$, that is, the ratio R_4/R_3, is confined to the narrow band of values shown by the shaded area in Fig. 6. The average ratio $y(1)$ of first order circle radii to the zeroth order circle radius (dotted line in Fig. 6) has a value of $y(1) \simeq 0{\cdot}402 \pm 0{\cdot}004$ and is therefore practically independent of R_2/R_1 and R_3/R_2. Further computations have shown that

$$\lim_{K \to \infty} y(K) = 0{\cdot}4028 \tag{5}$$

This explains the constant change of $\langle \ln r_{(K)} \rangle$ with K. Equations (3) and (5) are in agreement because $\ln 0{\cdot}4028 = -0{\cdot}90942$.

Fig. 6 also gives information about the second moment of the circle size distribution, $M_2(K)$, which is defined as

$$M_2(K) = \langle (\ln R_{(K)} - \overline{\ln R_{(K)}})^2 \rangle \tag{6}$$

The decrease in circle size per generation will vary within a narrow range of values only, so it is obvious that the increase in the second moment is also restricted. Calculations of the second moments of the circle size distributions for the areas I to VI showed that

$$\left(\frac{dM_2(K)}{dK}\right)_{K \geq 3} = 0{\cdot}052 \tag{7}$$

It should be noted that a generation of circle sizes is a complete distribution and not a random sample of a large distribution. Hence, we are interested in

$$s_0^2 = \frac{1}{N} \sum_1^N (x_i - \mu)^2 \tag{8}$$

and not in

$$s^2 = \frac{1}{N-1} \sum_1^N (x_i - M)^2 \tag{9}$$

where the x_i's form the distribution, μ is the true mean, s is the standard deviation and M is the experimental mean[10].

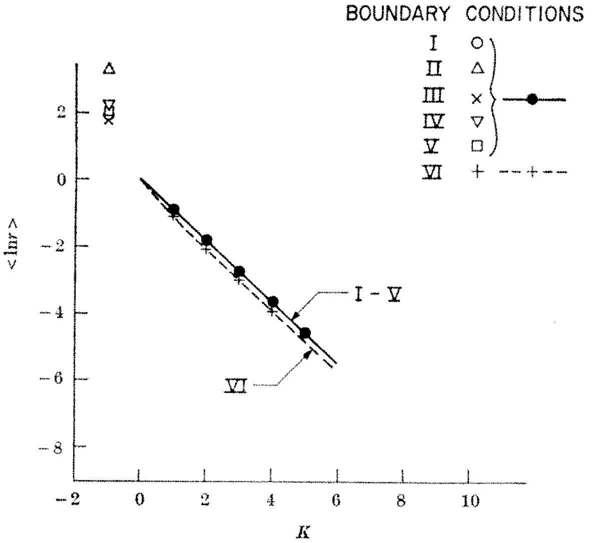

Fig. 5. Average logarithmic circle radius as a function of K for all six boundary conditions.

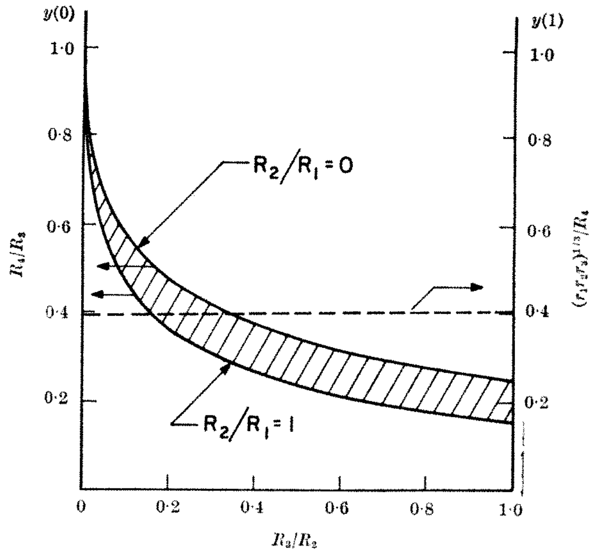

Fig. 6. Influence of R_2/R_1 and R_3/R_2 on the ratios $y(0)$ and $y(1)$ of zero- and first-order circle radii. Left hand ordinate and shaded area: ratio $R_4/R_3(y(0))$; right hand ordinate: geometric mean of first order circle radii ($y(1)$).

Analytic Expression

The circle size distributions in osculatory packing are weak functions of the boundary conditions and thus share important features. We can therefore construct an analytic expression that provides a good approximation to the osculatory distribution, regardless of the boundary condition. We use the fact, demonstrated above, that the decrease of the first moment of $\ln r_{(K)}$ with K approaches the constant value 0·90942, while the increase of the second moment with K likewise approaches the constant value 0·052. To derive the desired relation it is convenient to choose the boundary condition represented by the ideal tricuspid (condition I).

An approximation to $r_{(K)}$ with the aforementioned properties of the first and second moment can be derived from the identity

$$r_{(K)} = r_{ijk \ldots x} = R_4 \frac{r_i}{R_4} \frac{r_{ij}}{r_i} \frac{r_{ijk}}{r_{ij}} \cdots \frac{r_{ijk \ldots x}}{r_{ijk \ldots}} \tag{10}$$
$$(i, j, \ldots x = 1,2,3)$$

where the number of the indices $i, j, k \ldots x$ is equal to K. We stipulate that the ratios r_i/R_4, r_{ij}/r_i, and so on, can assume three distinct values c_1, c_2 and c_3 only. Equation (10) then becomes

$$r_{(K)} = r_{ijk \ldots x} = R_4 c_i c_j c_k \ldots c_x \; i, j, k \ldots = 1,2,3 \tag{11}$$

The assumption of distinct coefficients which repeat themselves within each generation is not unreasonable. There is indeed a solution of equation (2) with $R_2/R_1 = R_3/R_2 = R_4/R_3$, and the ratio was determined numerically to be 0·3460. The tricuspid with parent circles fulfilling these relations is precisely the ideal tricuspid, which was thus termed because the radii R_1 to R_4, and subsequently the smallest radii from each generation, $r_3, r_{33}, r_{333} \ldots$, form a geometric series with common factor 0·3460. Even if R_1 to R_4 do not fulfil the condition of constant ratios, the series of smallest circles from each generation will rapidly approach this factor. We will therefore arbitrarily choose one of the coefficients, c_3, to be equal to 0·3460. The coefficients c_1 and c_2 are determined so as to give the required behaviour of the first moment, $M_1(K)$, and the second moment, $M_2(K)$, of $\ln r_{(K)}$.

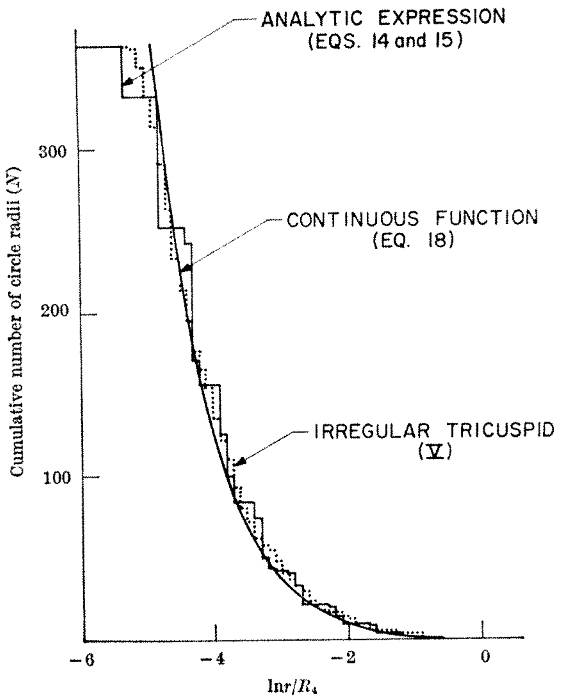

Fig. 7. Comparison of different cumulative distributions of circle radii.

We must have

$$\frac{\mathrm{d}M_1(K)}{\mathrm{d}K} = \frac{1}{3}\ln c_1c_2c_3 = -0{\cdot}90942 \qquad (12)$$

from the first condition, and

$$\frac{\mathrm{d}M_2(K)}{\mathrm{d}K} = \frac{1}{3}[(\ln c_1)^2+(\ln c_2)^2+(\ln c_3)^2]-\frac{1}{9}(\ln c_1c_2c_3)^2 = 0{\cdot}052 \qquad (13)$$

from the second. Using the value 0·3460 for c_3, equations (12) and (13) can be solved to yield $c_1=0{\cdot}555$ and $c_2=0{\cdot}340$. Equation (7) can now be replaced by

$$r_{ijk\ \ldots\ x}=R_4c_1{}^{\alpha}c_2{}^{\beta}c_3{}^{\gamma}=r(\alpha,\beta,\gamma) \qquad (14)$$

where α, β and γ take on any integral values subject to the restriction $\alpha+\beta+\gamma=K$. The multiplicity of any specific value $r(\alpha,\beta,\gamma)$ is given by the permutation

$$P(\alpha,\beta,\gamma) = \frac{K!}{\alpha!\,\beta!\,\gamma!} \qquad (15)$$

Equation (15) describes the probability distribution of the Kth order circle radii and together with equation (14) constitutes the desired analytic expression. The cumulative distribution of circle radii from all generations can be obtained by adding the contributions from each generation as calculated from equations (14) and (15). The result is shown in Fig. 7. The stepped solid line and the dotted line represent the cumulative distribution calculated from the analytic expression, and the cumulative distribution obtained from boundary condition V (the most commonly occurring irregular tricuspid), respectively, up to and including the radii of the circles of the fifth order.

The cumulative distribution function can also be derived directly from the knowledge that the number of radii within the jth generation is equal to 3^j and that

$$\langle \ln r_{(j)}\rangle = \ln R_4 - 0{\cdot}90942j \qquad (16)$$

We assume that within the jth generation half of the radii are smaller than $\langle \ln r_{(j)}\rangle$. Then for all points ln $r=\langle \ln r_{(j)}\rangle$, the total number of circles with radii between r and R_4 will be exactly

$$Z(j)=1+3+3^2\ \ldots\ +3^{j-1}+\frac{1}{2}3^j \qquad (17)$$

Using the summation formula of a geometric series, and expressing j by ln r as in equation (16), we obtain the number of radii per interstice with a radius of r or larger than r as

$$Z(\ln r)=3^{-(\ln r/R_4)/0{\cdot}90942}-0{\cdot}5=(r/R_4)^{-1{\cdot}2080}-0{\cdot}5 \qquad (18)$$

The function $Z(\ln r)$ is also shown in Fig. 7, where it is represented by the unbroken solid line. It provides a very satisfactory representation of the actual distribution for the irregular tricuspid area. (It should be possible to obtain the asymptotic distribution of ln r also from Hirst's[8] Lemma 7 together with the results of Furstenberg and Kesten[11].)

The differential distribution of circle radii is derived from equation (18) as

$$n(r)\mathrm{d}r = \frac{\mathrm{d}Z(\ln r)}{\mathrm{d}r} = -1{\cdot}2080\,(r/R_4)^{-2{\cdot}2080}\,\mathrm{d}(r/R_4) \qquad (19)$$

It is evident that the smaller circles will be more numerous, for their number is increasing with a constant power of 2·2080 and does not depend on the boundary conditions.

From equation (18) an empirical value can also be obtained for Melzak's[7] exponent of osculatory packing S, for which his theorem 3 supplies the bounds $1{\cdot}035<S<1{\cdot}999971$. Based on the calculations of Gilbert[6], Melzak has suggested a value in the neighbourhood of 1·3 for S. Because equation (18) is the more satisfactory the larger the number of circles, 1·208 seems to be a good empirical value for S.

Optimal Circle Size Distribution

The derivation of equations (14) and (15) assumed that the largest circle radii in each generation decrease from generation to generation by a factor of $c_1=0{\cdot}555$. If equation (19) is a good approximation to the circle size distribution in osculatory packing, we shall not expect the Kth generation to contain any circle with a radius larger than $R_4c_1{}^K$. The osculatory packing of K-1 generations of circles therefore yields the optimal cumulative distribution for $c_1{}^K<r/R_4<1$, because the cumulative distribution of circles between these limits will not be changed by packing the Kth and any further generations of circles. The optimal covering of a given area is therefore also a weak function of the boundary conditions and can be approximated closely by equation (19).

Short-term Periodic Variations following an Optical Flare of Sco X-1

We have recently carried out a detailed investigation of the "flickering" of the optical source associated with Sco X-1 using the technique of power spectrum analysis to search for periodicities in the photometric data of Sandage *et al.*[1]. In common with others[2,3], we have found no evidence for stable periodic structure when the time series resulting from a whole night's observations is analysed. But we have also studied shorter stretches of data (500 to 900 consecutive data points) chosen so that no large-scale flaring occurred during these periods. Many of these short runs seem to contain periodic structure at one or more frequencies, corresponding to components with amplitudes in the range 0·1 to 0·5 per cent of the mean intensity over the appropriate interval. The results of this work (unpublished) have encouraged us to look more closely at certain regions of the data.

It is natural to suppose that the larger-scale flaring of the source may influence the small-scale flickering, and in the data which we have available there is one instance of a particularly large and well defined flare which occurred just before data point 610 (in the notation of Sandage *et al.*) on the night of April 3, 1967. Our present investigation has therefore concentrated on the fairly smooth stretch of data immediately following this flare, in order to find any detectable influence of the flare on the flickering. We have already discussed the technique of power spectrum analysis in another context[4], and the application here differs only in detail from that already described. The data were analysed in stretches of 500 data points with 100 lags, so that the bandwidth, using a "hamming" window, is 0·0025 Hz. In each case the autocovariance function was "detrended" using a least-squares approximation in order to remove the effects of drift in the mean intensity level, and the raw time series themselves were prewhitened using a simple difference filter with constant 0·9. Each data point corresponds to an integration time of 2 s within a sampling interval of 5 s (ref. 1). Figs. 1–4 show the resulting power spectra for data points 610–1,109, 810–1,309, 1,010–1,509 and 1,210–1,709, respectively, from which it is clear that the flare immediately preceding has had a pronounced effect on the smaller and more rapid variation.

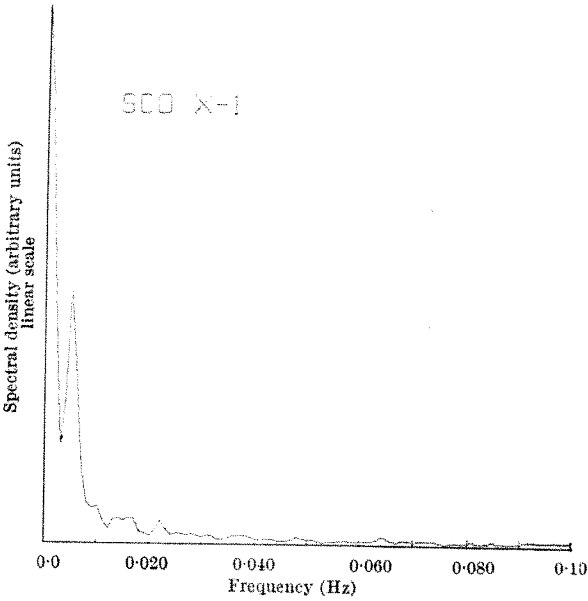

Fig. 2. Power spectrum obtained from data points 810–1,309 (post-flare).

Just after the flare (Fig. 1) we see that a fairly broad band of frequencies centred on 0·006 Hz (corresponding to a

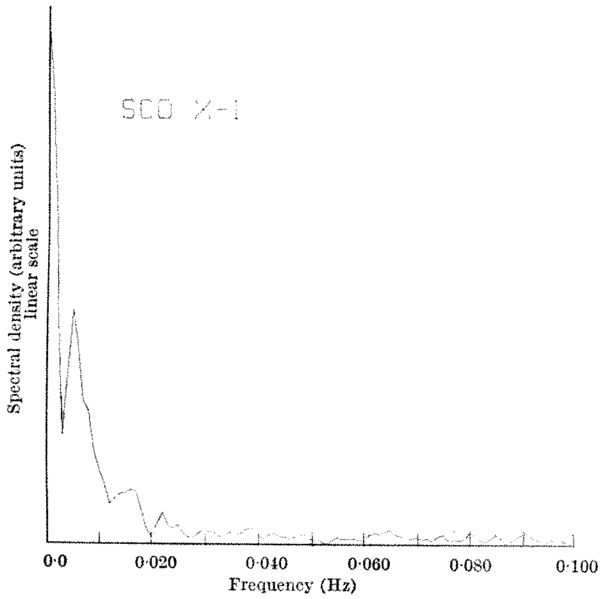

Fig. 1. Power spectrum obtained from data points 610–1,109 (post-flare).

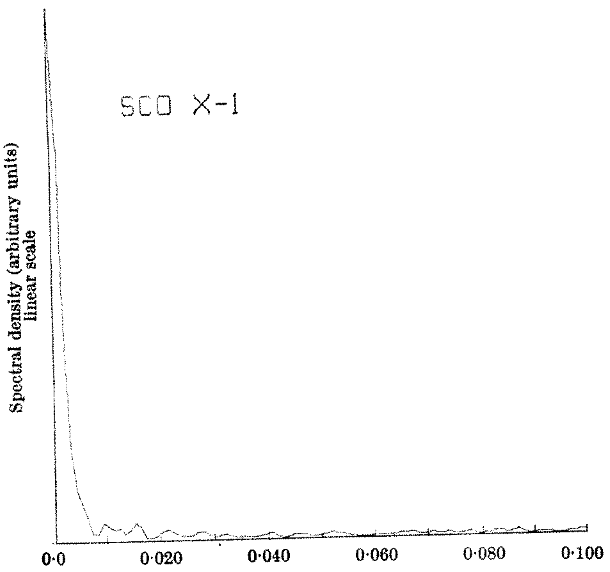

Fig. 4. Power spectrum obtained from data points 1,210–1,709 (post-flare).

period of ~170 s) has been excited. Shortly after this (Fig. 2) the height of the peak at 0·006 Hz is even greater, but it is rather more sharply defined, suggesting a relaxation of the periodic variation into a "fundamental" mode in the absence of any continuous excitation. Subsequently, the energy associated with this variation is rapidly dissipated (Fig. 3) until some 1,000 data points (~80 min) after the flare it is no longer detectable (Fig. 4), and the power spectrum has the same overall appearance as that for data points 1–500 immediately preceding the flare (Fig. 5). The largest peaks (comparing with Figs. 1 and 2) seem to represent an oscillation with amplitude ~1 per cent of the mean optical intensity of the source at this time, because a calibration sinusoidal variation of this magnitude superimposed on the original time series produces a comparably sized peak in the power spectrum.

It is not clear how energy is transferred from the flare to produce periodic flickering, so discussion of possible models to account for this behaviour must await completion of the more detailed study of the optical variation of Sco X-1 currently being prepared. Here we wish only to emphasize the reality of the large peak at 0·006 Hz, the height of which above the background noise may be estimated from comparison with Figs. 4 and 5, where this peak is totally absent.

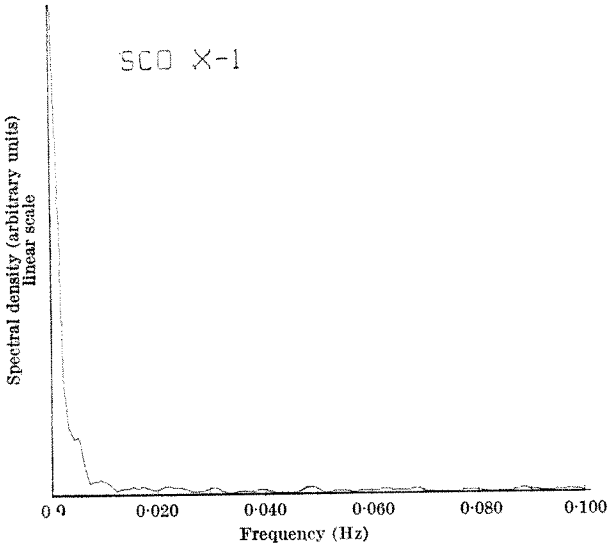

Fig. 5. Power spectrum obtained from data points 1–500 (pre-flare).

We thank Drs J. Kristian and A. Sandage for providing their photometric observations of Sco X-1 as a deck of punched cards, and Professor J. W. Tukey for discussions concerning details of the power spectrum analysis. J. R. G. holds an Isaac Newton studentship from the University of Cambridge and a minor studentship from University College, Cambridge.

Improved Parameters for Seven Pulsars

Positions, pulse periods and mean pulse energies are important parameters of pulsars. For many pulsars, particularly those discovered at the Molonglo Radio Observatory, the right ascension measurement has small error limits while the declination is not well determined. Observations at 410 MHz using the 300 foot transit telescope of the National Radio Astronomy Observatory have therefore been undertaken to determine more accurate declinations and periods for several pulsars. Mean pulse energies at 410 MHz have also been measured.

The observations were made during the period November 17–23, 1969, using a dual channel receiver with two feeds spaced by one beamwidth (35′ arc) in declination. The feeds, which were linearly polarized with position angle 90°, could be displaced off axis in the east–west direction, allowing the source to be tracked for up to 40 min. The detected outputs from the two channels were continuously sampled at 5 ms intervals by a digital computer and stored on magnetic tape. The i.f. bandwidth was 5·0 MHz for low dispersion pulsars and 0·5 MHz for those pulsars where the dispersion broadening was greater than 5 ms at 5·0 MHz bandwidth.

In subsequent analysis the data were averaged in 2 min blocks and the pulse profile obtained for each 2 min average. The source declination was calculated from the ratio of pulse amplitude in the north and south beams. Pulse arrival times were determined by fitting a mean pulse profile to each 2 min average. These arrival times were reduced to the barycentre, using an ephemeris generated at Lincoln Laboratory, Massachusetts Institute of Technology, and kindly supplied by Dr I. I. Shapiro, and periods calculated by making a least squares fit of a straight line to the data. Mean pulse energies were determined by averaging all data obtained, usually recorded on four or more days with 20 to 40 min of data each day. The effective pulse width, defined as the pulse energy divided by peak flux density, was also calculated.

Results for pulsars 0031 – 07 (ref. 1), 1237 + 25 (ref. 2), 1706 – 16 (ref. 3), 1818 – 04 (ref. 4), 1911 – 04 (ref. 3), 2022 + 51 (ref. 5) and 2218 + 47 (ref. 6) are given in Table 1. Right ascensions are taken from the original references. Periods are given in units of atomic (A.1) seconds and errors quoted are the sum of the r.m.s. timing errors

X-ray Scattering by Grains in the Direction of the Crab Pulsar and Sco XR-1

MOST of the X-ray emission from the Crab Nebula is from a diffuse cloud approximately 100″ in size[1,2], and about 10 per cent of the total X-ray flux is in pulsed form[3,4], presumably from the optical pulsar. Slysh[5] suggests that all of the X-ray flux originates in pulsed form at the pulsar and that scattering by grains washes out the time coherence and produces the observed angular size. This article is a discussion of the hypothesis of Slysh from the observational point of view.

Three parameters are needed to specify the X-ray scattering from grains: the number of scattering grains, N; the average size of these grains, a_0; and the grain material. X-rays undergo Thompson scattering by electrons in the grains, and the grain material specifies the number density of electrons. This is roughly similar for most possible materials, and, so for a first order approximation, we need only specify N and a_0. The observational data give us the ratio of scattered to unscattered photons and the scattering angle of the radiation. In principle, then, both N and a_0 can be determined.

In order to scatter 90 per cent of the source flux as required by the pulsar source hypothesis, the X-ray scattering depth, τ_X, must be 2·4. Overbeck[6] shows that for a given wavelength, λ, essentially all the scattered X-rays fall within a cone with half angle $\theta \simeq \theta_c/2$, where $\theta_c = \lambda/a_0$. The data on the size of the X-ray source in the Crab[2] can be used to find the average grain size once the effective wavelength of the measurement is known. Using parameters appropriate to this measurement, we have determined this wavelength from the relation

$$\langle E \rangle = \frac{\int E[\varepsilon(E)S(E)E^{-2}]\mathrm{d}E}{\int[\varepsilon(E)S(E)E^{-2}]\mathrm{d}E} \qquad (1)$$

where $\varepsilon(E)$ is the detection efficiency of the counter, $S(E)$ is the source spectrum of the Crab Nebula, and the factor E^{-2} accounts for the energy dependence of the efficiency of grain scattering. We find that $\langle E \rangle \simeq 5$ Å, and hence that $a_0 = 1$ µm. This is almost seven times the average grain size required to produce the scattering law which is observed in the visible[7].

A second test of the Slysh hypothesis uses the source position obtained on the same flight. To first order, X-rays scattered by a cloud would appear to be distributed with circular symmetry about the central source. As Overbeck points out, however, the alignment of elongated grains might produce an effect similar to Fraunhofer diffraction which would destroy this symmetry. Further, nonuniformities in the distribution of grains (say, by the chance occurrence of a cloud edge coinciding with the line of sight of the source) would move the centroid of the X-ray distribution away from the line of sight of the source. We have not tried to evaluate the effect of elongated grains because of our poor knowledge of grain shapes. We have, however, evaluated the effect of an off-axis distribution of grains on the position of the X-ray centroid. Observationally, Oda *et al.*[2] concluded that the X-ray centroid of the Crab was displaced 22″ from the position of the optical pulsar. Because the one sigma observational errors were about of this order, this discussion is perhaps most useful as an indication of the magnitude of the expected effect.

Suppose that along the line of sight to the X-ray source there is a mean number of clouds per unit volume, N, each having a radius s. We are concerned with cloud edges which lie within some angle θ to the line of sight for which each cloud at a distance r contributes an annular cross-section of $4\pi r\theta s$. The expected number of edges intercepted is the integral of the probability cross-section along the line of sight

$$N = \int_0^R 4\pi r\theta s\, N\mathrm{d}r = 2\pi s\theta\, NR^2 \qquad (2)$$

Using $s = 7·5$ pc and $N = 3 \times 10^{-5}$ pc^{-3} (ref. 8), we find the most probable number of edge intercepts is 0·6 for $\theta = 22''$ and $R = 2$ kpc. Variations about the mean occur and are given by Poisson's probability law. For our case, the probabilities of zero, one and two edges are 0·55, 0·33 and 0·10. More than two edges have a probability of occurrence of only 0·02.

If the mean visual absorption per cloud is 0·25 magnitudes[8], then there are about eight clouds in the line of sight to the Crab. Hence, an average cloud will scatter at most 11 per cent of the source flux, while even fewer X-rays will be scattered if the cloud fails to fill the cone of sight. Consequently, one cloud edge cannot displace the observed brightness centroid by more than 11 per cent of the 22″ angle within which scattering is appreciable. Two edges could produce a 22 per cent displacement but only if they were aligned. The net result is a displacement of only two or three arc seconds, which cannot explain the off-axis displacement observed.

X-ray data on Sco XR-1 are sufficiently precise to be applied to a discussion of the Slysh hypothesis. Both τ_X and the visual absorption, A_V, are proportional to the number of intervening grains. Assuming that the grains are similar in the direction of the Crab and Sco XR-1, we can form the relation:

$$\tau_X(\text{Sco XR-1}) = \tau_X\,(\text{Crab})\,\frac{A_V\,(\text{Sco})}{A_V\,(\text{Crab})} \qquad (3)$$

We have already concluded that τ_X (Crab) is 2·4 if the pulsar source hypothesis is valid. For the Crab A_V falls in the range from 1·6 to 1·9 (ref. 9). Values obtained for the extinction in the direction of Sco XR-1 vary from a low of 0·39 based on Eggen's work[10] to an upper limit of 2 deduced by Johnson[11]. We are rather sceptical of the lower value. It has long been known that the Upper Scorpius region is heavily reddened. The extensive data of Gutierrez-Moreno and Moreno[12] indicate that at a distance modulus of 6·0 to 6·5 in the general direction of Sco XR-1, the colour excess will be larger than 0·28. We attach greatest weight to the work of Sandage *et al.*[13], who concluded from an analysis of the reddening of seven stars within 9′ of Sco XR-1 that the excess of colour is approximately 0·23 over the distance interval between 100 and 400 pc. We conclude that τ_X (Sco XR-1) as determined from equation (3) will fall between 0·9 and 1·05.

To compare this result with data on the size of Sco XR-1 (ref. 2), we generate a synthetic X-ray distribution with 55 per cent of the flux scattered and the remainder in the line of sight corresponding to $\tau_X = 0{\cdot}9$. The angular distribution of the scattered radiation can be obtained from Overbeck's curves once the characteristic scattering angle is determined. Evaluating relation (1) using the spectrum of Sco XR-1 and with the appropriate instrumental parameters, and choosing $a_0 = 0{\cdot}2$ μm for compatibility with optical reddening data, we find $\theta_c \simeq 8{\cdot}5'$. We then sum the direct and scattered components of the flux and compare the resultant distribution with the experimental results. As opposed to the instrumental width of about 78″ which was observed, this distribution would have been detected as an extended source with a diameter of more than 160″. Repeating this procedure for a number of different X-ray scattering depths, we find that with τ_X (Sco) as low as 0·6, the effect of scattering would still have been detected. We therefore conclude that the X-ray scattering hypothesis for the Crab is at variance with the X-ray data obtained on Sco XR-1.

The final point considered in this analysis was the amount of optical reddening that would be produced in the direction of the Crab Nebula by those grains needed to produce the required X-ray scattering. We first picked a grain material and characteristic size distribution. Using Overbeck's work, we then derived the number of these grains necessary to produce the required X-ray scattering. Using these parameters with the work of Van de Hulst[14], we then computed the amount of optical extinction. For ease of computation, a size distribution of the form $\mathrm{d}n/\mathrm{d}a \sim 1/a_0 \exp\,(-a^2/2a_0^2)$ was used which is similar but not identical to typical distributions discussed by Greenberg[7]. This procedure was repeated for a range of average grain sizes for each of a number of different grain materials. In Fig. 1 we have plotted A_V for the required number of grains against the average grain size for several different materials. We have used one composite grain: a graphite core 0·05 μm in radius surrounded by an ice mantle of sufficient thickness to produce the grain size indicated. We also computed the reddening for single-sized grains of SiO_2 to determine the effect of a grain distribution on the optical reddening. We have drawn a line on this plot at $A_V = 1{\cdot}9$ which corresponds to the largest reddening in the range cited earlier for the Crab Nebula. The reddening predicted for all grain materials except iron is in clear violation of the observations for all reasonable grain sizes. Iron grains with an average size of 0·3 μm will fit the observations, but few would consider this a viable grain model. We conclude that the optical effects of any grains sufficient to produce the observed X-ray scattering are incompatible with the reddening data on the nebula. This is unquestionably the strongest argument presented in this discussion.

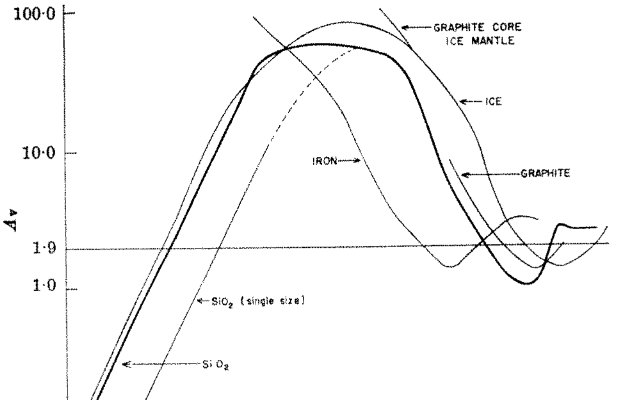

Fig. 1. Optical extinction in the direction of the Crab Nebula plotted against average grain size for those grains required to produce the observed X-ray effects from the pulsar. An upper limit to the extinction which is observed is indicated by a line at $A_V = 1{\cdot}9$.

Intuitively one might hope that X-ray scattering would be dependent on smaller grains than optical scattering and hence could provide data on the distribution of sizes of grains which is now unattainable. X-ray scattering efficiencies do indeed become larger than optical scattering efficiencies for grain sizes smaller than about 0·005 μm. The X-ray scattering cross-section per gram of grain material, however, is proportional to the grain radius for small grain sizes. Hence with 0·005 μm grains, fifty times more material would be required to produce scattering equivalent to that produced by 0·25 μm grains.

We have examined the relatively crude data which are now available on Sco XR-1 to see what information they can give about the larger grains. To do this, we first use the optical data available on Sco XR-1 with the relationship $A_V = 1{\cdot}086\ \tau_V = 1{\cdot}086\ NQ_V\pi a_0^2$ to obtain a value of N in terms of a_0. Here we use a value of 3 for Q_V, the optical scattering efficiency, in anticipation of our final result. We then use this N with the upper limits on τ_X obtained previously to obtain an upper limit on the value of σ_X. Van de Hulst[14] has shown that for X-rays the scattering efficiency is given by

$$Q_X = \frac{\sigma_X}{\pi a_0^2} = \frac{\rho^2}{2} = \frac{(2a_0\rho_e r_e\lambda)^2}{2}$$

where ρ is the phase shift across the grain, ρ_e is the number density of electrons in the grain and r_e is the classical electron radius. Our derived upper limit to σ_X can then be used in this formalism to obtain an upper limit on a_0 once we specify the grain material. Using Q_X (effective) $= 2Q_X(a_0)$ which is appropriate for X-rays, we find $a_0 \leq 1{\cdot}6$ μm for ice particles and $a_0 \leq 0{\cdot}13$ μm for iron grains. Hence although the existing X-ray data are clearly not sufficient to affect our present ideas concerning grains, we are not far from the point where this work will directly impact this topic.

Clearly much information about interstellar grains will be obtained from observations of those X-ray objects with optical counterparts in which both reddening and X-ray scattering can be observed. In principle there will be more observational data (τ_X, θ_c, A_V, and reddening as a function of wavelength) than grain parameters to be specified (N, a_0 and composition). Unfortunately, for most grain materials the optical scattering efficiency is between five and ten times larger than the X-ray scattering efficiency for grain sizes from 0·1 to 1 μm. Hence most objects in which X-ray scattering is pronounced are likely to be totally obscured in the visible. Multisized grain distributions have, however, been proposed with some components centred around sizes larger than 1 μm. For grains of this size the optical and X-ray scattering efficiencies of most materials are roughly similar and hence this may provide a means of evaluating the multicomponent grain size models proposed.

Magnets in Electromagnetic Theory

Two recent communications on electromagnetism[1,2] exemplify the two basic approaches to the problem. It is possible to regard E, D, H and B as labels identifying different properties which it is convenient to distinguish, and in the main this is the approach taken by Rosser[1]. On the other hand, it is possible to look for physical realities corresponding to each of these terms and to examine various relationships to see whether these correspond with "reality". This is basically the approach of Stopes-Roe[2].

The first approach is quite unexceptional but is rarely carried out consistently. It is, for example, usually assumed as *a priori* "fact" that charge is a fixed entity and that the movement of a real charge from one medium to another does not in any way affect the magnitude of the charge. I know of no experiment which proves this convenient assumption. There is no doubt that electrostatic calculations would be very much more difficult in a system in which the magnitude of a charge was a function of the medium (for example, $q=q_0\,\varepsilon^{-1/2}$, ε being the dielectric constant of the medium). This is a sufficiently good reason for defining a charge as being an entity which is independent of the medium.

The corresponding case of the magnetic dipole is rarely, if ever, considered in terms of convenience, but reference is made to hypothetic or real experiments. The results of these experiments are always open to different interpretations and no conclusive proof of one interpretation or another is ever produced. For example, experiments are made with long thin "hard" magnets which it is assumed may be taken to represent accurately the properties of elementary magnetic dipoles. This, however, is open to the objection that this form of magnet is that most influenced by demagnetizing effects. The classical ring magnet with a small gap is least affected by demagnetizing effects.

Experiments made with ring magnets would tend to show that "real" magnets produce a constant flux (constant B), but thin magnets in the same type of experiment will appear to produce a constant H.

It is further assumed that because a current carrying solenoid produces some magnetic effects like those of a permanent magnet then the latter "is" a system of atomic currents.

A solenoid is usually connected to a source to supply the current in it, however. In this case when the external medium is changed (even if the solenoid core is an evacuated enclosure in which the medium does not penetrate) energy is taken from or given to the source.

A permanent magnet, however, has no such external source from which it can draw energy and in this it differs from the hypothetical solenoid.

This objection can be overcome by postulating a superconducting solenoid carrying a current as being the equivalent of a permanent magnet. This concept avoids the problem of interchange of energy with a source but introduces another basic difficulty. A superconducting ring has an infinite current induced in it if the magnetic flux linking with it changes. If, therefore, the medium around such a solenoid is changed the superconductor prevents any change of magnetic flux through it. Compensating changes occur in the current circulating in the solenoid.

This type of solenoid therefore has the property that the magnetic flux linking it is independent of the medium. It is therefore the equivalent of a magnet of constant B (unlike the ordinary constant current solenoid which is the equivalent of a magnet of constant H).

The superconducting solenoid cannot be described by writing its magnetic moment as $m=IA$ because the current I involved is not a constant but is a function of the medium, falling if the permeability of the surroundings increases, and vice versa.

A magnet made up of superconducting elements would probably act more like real permanent magnets than any of the other models proposed. It would be a constant flux magnet (and therefore would be a direct analogue of the constant electrostatic charge which is generally favoured) and its properties would be very similar to those of single-crystal magnetic materials.

If, therefore, it is considered necessary to invent atomic concepts to account for macroscopic behaviour—instead of accepting E, D, H and B as convenient definitions—it seems more logical to take an elementary permanent magnet as a constant flux device and not as a constant H device.

Derivation of Rate Equations used in Thermogravimetry

There have been many attempts to extract kinetic parameters, such as energy of activation or order of reaction, from dynamic thermogravimetric data[1-3]. The main reasons for using thermogravimetry (TG) instead of the more traditional isothermal methods are that it is unnecessary to know the time and temperature of the onset of decomposition, and with TG it is possible to use only one set of experimental data to derive the desired parameters. In other methods, several isothermal experiments must be performed at different temperatures to yield a value for the energy of activation. It should be noted, however, that some of the best TG methods (Friedman[4] and Osawa[5]) entail several experiments at different heating rates.

For homogeneous decomposition reactions which evolve volatile products and leave a residue, for example, the thermal decomposition of polymers, the thermobalance results are analysed in the following way

$$\frac{dC}{dt} = k.\ f(C) \tag{1}$$

where (dC/dt) is the rate of fractional conversion, k is defined as the rate constant and $f(C)$ is some function of the fractional conversion, frequently written as $(1 - C)^n$ where n is the apparent reaction order.

k is then related to the temperature (T) and the activation energy (E) by the Arrhenius equation

$$k = A \exp(-E/RT) \tag{2}$$

A is the pre-exponential factor and R the gas constant.

Finally equation (2) is substituted in equation (1) to give

$$\frac{dC}{dt} = A.\ \exp(-E/RT)\ .\ f(C) \tag{3}$$

We believe this step is incorrect. The substitution for k, the "rate constant", can only be made for an equation involving an isothermal rate, that is

$$\left(\frac{dC}{dt}\right)_T = A.\ \exp(-E/RT)\ .\ f(C) \tag{4}$$

It can also be shown that equation (3) is not, as it is generally assumed to be, equivalent to equation (4), except under a special condition. If C is considered to be a function of time and temperature only, we have

$$C = f(t,T) \tag{5}$$

On differentiating,

$$dC = \left(\frac{\partial C}{\partial t}\right)_T dt + \left(\frac{\partial C}{\partial T}\right)_t dT \tag{6}$$

and

$$\frac{dC}{dt} = \left(\frac{\partial C}{\partial t}\right)_T + \left(\frac{\partial C}{\partial T}\right)_t .\beta \tag{7}$$

β is the heating rate (dT/dt). For purposes of comparison with (4), equation (7) may be rewritten as

$$\frac{dC}{dt} = \left(\frac{dC}{dt}\right)_T + \left(\frac{dC}{dT}\right)_t .\beta \tag{8}$$

From equation (8) it can be seen that the thermogravimetric rate (dC/dt) is not equal to the isothermal rate $(dC/dt)_T$ except, of course, when the heating rate (β) is zero (isothermal conditions). Use of equation (3) is therefore an incorrect simplification of the true state of affairs. The correct equation should be

$$\frac{dC}{dt} = A \exp(-E/RT)\ .f(C) + \beta\left(\frac{dC}{dT}\right)_t \tag{9}$$

When $\beta = 0$ in equation (9), (dC/dt) becomes $(dC/dt)_T$ the isothermal rate and the use of equation (3) is permissible.

We have applied several of the more commonly used methods of analysis of programmed thermogravimetry[6] to the thermal degradation of a single polymer in standard conditions. We found very poor agreement for the numerical values of the kinetic parameters evaluated, which suggests that the basic equations may be inaccurate. We therefore consider that only isothermal methods can be used to evaluate the order of the reaction, the pre-exponential factor and the activation energy. From equation (4), it seems that the following method fulfils the requirement of not defining the starting time of the reaction.

Taking logarithms of equation (4) gives

$$\log_e\left(\frac{dC}{dt}\right)_T = \log_e A + \log_e f(C) - \frac{E}{RT} \tag{10}$$

To obtain E, the logarithm of the isothermal reaction rate should be plotted against $1/T$, the reciprocal temperature (K^{-1}), at constant conversion. The measurement of A and n would require an assumption of the value of $f(C)$. The method may be repeated for different conversions, building up a picture of the change of the kinetic parameters with the extent of reaction. This technique needs data from several experiments carried out at different isothermal temperatures.

In examples for which programmed thermogravimetry and isothermal analysis give similar values for the activation energy, it must be concluded that the second term, $\beta\ (dC/dT)_t$, is very small compared with the first and hence negligible error is introduced by neglecting it.

Liquid Phase Inversion

The phase behaviour of the nitrogen–methane–ethane system in the vicinity of −255° F has been reported in an earlier communication[1]. The system has subsequently been studied at lower temperatures by lowering the freezing point of the isopentane bath liquid with propane gas. It was found that a liquid phase inversion took place between the temperatures −255° F and −263·3° F, the bottom liquid layer being the nitrogen-rich phase at −263·3° F and the ethane-rich phase at −255° F. Binodal curves for the saturated liquids at these two temperatures are shown in Fig. 1, in which BL denotes the bottom layer. The phase inversion temperatures together with the equilibrium liquid–liquid compositions obtained in this investigation are listed in Table 1. In all cases investigated, the nitrogen composition in the equilibrium vapour phase was greater than 97 per cent.

The liquid phase inversion temperature for the binary system nitrogen–ethane was found to be −263·3° F. A similar phase inversion was reported by Schindler, Swift and Kurata[2] for nitrogen–propane at approximately

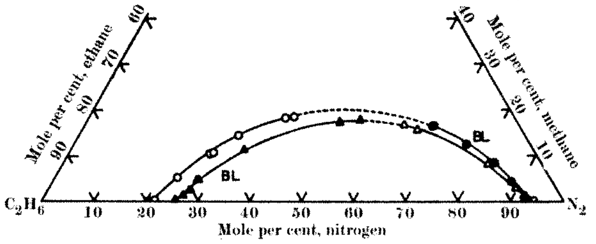

Fig. 1. Binodal curves for the nitrogen–methane–ethane system at two temperatures. ○ ●, −263·3° F; △ ▲, −255° F.

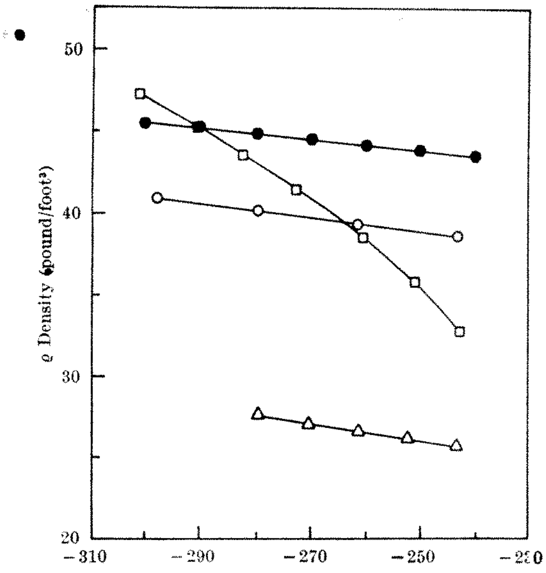

Fig. 2. Liquid densities of pure components. □, Nitrogen; △, methane; ○, ethane; ●, propane.

−292° F. These phase inversions are probably brought about by the decrease of liquid nitrogen density[3] with the increase of temperature taking place faster than for the paraffins (ref. 3 and unpublished results of J. Klosek and C. McKinley, presented at the International Conference on LNG, Chicago, April 1968) as shown in Fig. 2. This figure shows that the density curve for nitrogen crosses that for ethane at about −263° F, while it crosses that for propane at about −292° F.

Table 1. PHASE INVERSION TEMPERATURES AND LIQUID-LIQUID EQUILIBRIUM COMPOSITIONS

−255·9	208·5	0·3511	0·1487	0·5002	0·7443	0·1258	0·1299
	208·3	0·7392	0·1271	0·1337	0·3401	0·1463	0·5126
−255·4	213·0	0·4829	0·1850	0·3318	0·6324	0·1651	0·2025
	212·3	0·6266	0·1662	0·2072	0·4829	0·1848	0·3223

We reported the formation of a third liquid layer for the system nitrogen–methane–ethane in our previous communication[1]. The results of this investigation indicate that the composition of the top (third) layer is virtually identical with that of the bottom layer, and that there are only two liquid phases present because the relative amount of the top and the bottom layers can be manipulated by a sudden change of the vapour recirculation rate. The formation of the third liquid layer seems to be connected with the liquid phase inversion effect, and could be brought about by slight temperature non-homogeneities in the apparatus in the vicinity of a phase inversion point.

We thank Dr M. B. King of the University of Birmingham for his valuable comments on the manuscript.

Pyrolysis of Early Pre-Cambrian Onverwacht Organic Matter ($>3\times10^9$ yr old)

CARBONACEOUS matter and microstructures of unknown origin in the oldest known sedimentary rocks (part of the Onverwacht Series in South Africa; $>3\cdot0\times10^9$ yr old) have created considerable interest (unpublished work of B. N., L. A. Nagy, C. G. Engel, A. E. J. Engel, G. O. W. Kremp and C. M. Drew (1967), and refs. 1–5). Because these rocks may be as old as $\sim3\cdot5\times10^9$ yr, while the generally accepted age of the Earth is $4\cdot5\times10^9$ yr, carbon compounds in the Onverwacht Sediments may be derived from some of the first living matter on Earth or perhaps from prebiological substances. Most sedimentary rocks are porous, and even the Onverwacht carbonaceous and argillaceous chert has been found to exhibit a small degree of liquid permeability[6]. Part of the soluble organic compounds could therefore have been brought in and deposited in the Onverwacht by percolating solutions at a later geological age. But, on the other hand, the insoluble organic polymeric substance, or kerogen, seems to be basically indigenous and most of it, if not all, was deposited with the rocks in Onverwacht times. We have therefore analysed the Onverwacht kerogen, hoping that this might elucidate the nature of the carbon compounds that were present on the Earth $\sim3\cdot5\times10^9$ yr ago.

The Onverwacht Series of rocks are part of the Swaziland System of the Barberton Mountain Land in South Africa. It consists basically of mafic, ultramafic and felsic lavas and pyroclasts with subordinate amounts of various sediments, such as cherts, shales and carbonate rocks. The overlying (younger) Fig Tree and Moodies series are composed mostly of sedimentary rocks. The Onverwacht has suffered considerable metamorphism in places, while at other locations the metamorphic overprint appears to be less severe. Recent work by Viljoen and Viljoen[7] led to the subdivision of the Onverwacht into six formations: The Sandspruit (oldest), Theespruit, Komati, Hoogenoeg, Kromberg and Swartkoppie (youngest), and they found that the Onverwacht is 50,000 feet thick stratigraphically. One of the sedimentary rock samples analysed in our study came from the upper part of the 6,200 foot thick Theespruit formation which overlies the 7,000 foot thick basal Sandspruit. This is a sample of the oldest known sediment on Earth. Other sediments analysed came from the upper Onverwacht, (the upper and middle portions of the 6,300 foot thick Kromberg formation), and one sample came from the overlying Fig Tree Series.

Finely ground samples, 100–200 mg, were pyrolysed in a modified Hamilton pyrolysis unit for 5 min at 500° C under a stream of helium (~5 ml./min). The pyrolysis unit consisted of a quartz tube, externally heated to 500° C, followed by an oven and heated transfer line maintained at 200° C. The heated transfer line was directly connected to a Perkin-Elmer model 226 gas chromatographic unit which in turn was connected through a Watson-Biemann molecular separator to a Hitachi RMU-6E single-focusing mass spectrometer. The heated transfer line from the pyrolysis unit to the gas chromatograph contained a liquid nitrogen trap in which the products accumulated during pyrolysis but which did not interfere with the helium flow. After pyrolysis, the trap was rapidly heated to 250°–300° C in an adjustable oven which resulted in the instantaneous introduction of the products into the gas chromatograph. Reproducibility of the runs was good. Most runs were made on a polyphenyl ether-coated capillary column (50 feet × 0·02 inch internal diameter), others were also run on Apiezon L (100 feet × 0·02 inch internal diameter) and Carbowax K-20*M* (50 feet × 0·02 inch internal diameter) capillary columns.

Simmonds *et al.*[8] have shown by a rather different technique that pyrolysis can be used to study early

Pre-Cambrian sedimentary organic matter; they used a Fig Tree rock sample. Fig. 1 shows gas chromatographic traces of the pyrolysis products of the Onverwacht and Fig Tree sediments from our study. These traces represent the total pyrolysable organic contents of the rocks, including all soluble organic matter; the latter, however, seems to be present in trace quantities only. Elementary analyses showed that these Onverwacht samples contained about 1 per cent total carbon, but available data suggest that the soluble organic substances in these rocks were in the <1 p.p.m. range. Table 1 shows the compounds that have been identified by mass spectrometry in the four samples shown in Fig. 1.

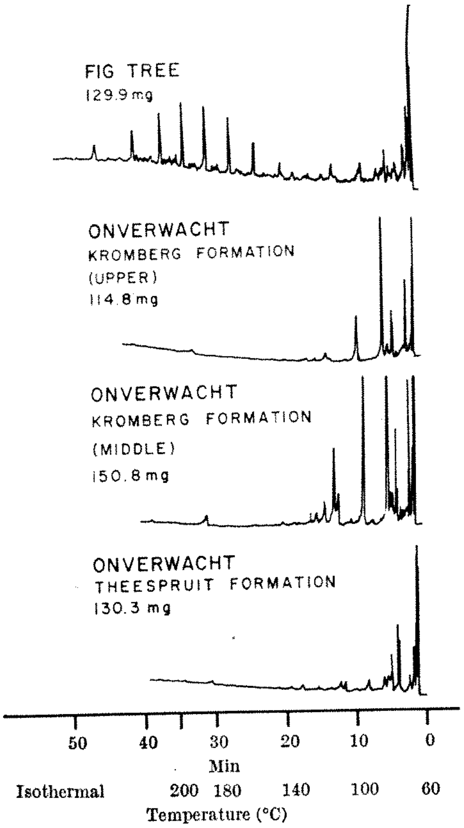

Fig. 1

Fig. 1 and Table 1 indicate that the Onverwacht samples contain mainly aromatic degradation products of the kerogen, while the Fig Tree sample shows an abundance of *n*-alkanes, which are usually thought to be of biological origin. It has been shown, for example, by Levy and Paul[9], that *n*-alkanes are not substantially degraded by the experimental conditions used in this pyrolysis study. It is difficult to account for an aromatic-type kerogen from biological sources in early Pre-Cambrian times, long before the appearance of the abundant aromatic biochemical, lignin. However tempting it may be to suggest that life first arose in Fig Tree times, it is not possible to draw this conclusion until samples from the entire Fig Tree and Onverwacht have been studied and compared, and, most important, until the relative metamorphic effects (which may lead to aromatization) on the Fig Tree and Onverwacht strata are compared and evaluated. In this context the microstructures found in the Onverwacht are morphologically better developed than those in the Fig Tree Series studied so far; the latter are thought by some investigators to be fossil algae. In conclusion, the origin of the aromatic kerogen is still unknown, although it has been suggested[10] that such a composition might be derived from living systems.

Table 1

Saturated hydrocarbons	Mono-unsaturated hydrocarbons	Poly-unsaturated hydrocarbons	Aromatic hydrocarbons	Hetero-atomic compounds
		Fig Tree		
Methane	Ethylene	C_5 Diene	Benzene	CO_2
Ethane	Propylene	C_6 Diene	Toluene	COS
Propane	2 Butenes	C_7 Diene	Ethyl benzene	SO_2

BIOLOGICAL SCIENCES

Observations on the Primary Structure of the 23S Ribosomal RNA from *E. coli*

An understanding of the primary structures of the large ribosomal RNAs should lead to greater insight into the structure of ribosomes and the way in which they work. Nucleotide sequences within the 16S RNA of *Escherichia coli* have recently been studied[1], but little is known about the primary structure of the 23S RNA (refs. 2–5). Two sorts of observations have been reported, however, which might be of general significance in considering the structure and evolution of this molecule: (*a*) The 23S and 16S ribosomal RNAs of *E. coli* have been found to compete with each other in hybridizing with *E. coli* DNA (refs. 6–9). This would indicate that they share some nucleotide sequences in common. (*b*) It has been suggested that the nucleotide sequences in the neighbourhood of the methylated nucleotides each occur twice within the 23S RNA (refs. 2, 3), implying that sequence repetition could be widespread.

One of us[3] has already pointed out that fingerprints of the T_1 ribonuclease digestion products of 16S and 23S RNAs are very different, thus indicating dissimilar primary structures. The sequences of the three largest methylated oligonucleotides[2,3] and of the 3′-terminal decanucleotide[4] of the 23S RNA display no striking homologies with any of the products of digestion with T_1 ribonuclease from the 16S RNA (ref. 1). Inspection of the fingerprints of the 16S and 23S RNAs reveals, moreover, that a greater variety of large oligonucleotides are released from the 23S RNA than from the 16S RNA, by the action of T_1 ribonuclease. The 23S RNA is twice as large as the 16S RNA (ref. 10), and has a very similar composition[11], so it is unlikely to consist of two similar or identical halves[2,9].

We have attempted to resolve these questions by studying the nucleotide sequences of a further twenty-four products arising from digestion of the molecule with T_1 ribonuclease. We have determined the complete nucleotide sequences of sixteen of these products. The sequences of the remainder were sufficiently defined to be useful for purposes of comparison with 16S RNA sequences. We have also determined the relative yield of these oligonucleotides after digestion of the 23S RNA.

We have used the methods for fractionating radioactive oligonucleotides introduced by Sanger *et al.*[12] (Fig. 1). A fingerprint of the digestion products is shown in Fig. 1, and nucleotide sequences are listed in Table 1, together with suggested frequencies of occurrence within the molecule.

On the basis of their nucleotide sequences and frequencies (see below), these products contain more than 300 nucleotides, corresponding to about 10 per cent of the molecule. Presumably these products arise from a series of points widely spread through the polynucleotide chain. If any parts of the 23S RNA sequence resemble sections of the 16*S* RNA, at least a few of these products would be expected to display significant nucleotide sequence homologies with the T_1 ribonuclease products arising from the 16S RNA (ref. 1). In fact, there seem to be no significant homologies with any of the 16S RNA sequences. We believe therefore that the inferences drawn from the hybridization studies are incorrect, and that the 23S and 16S ribosomal RNAs are genetically unrelated.

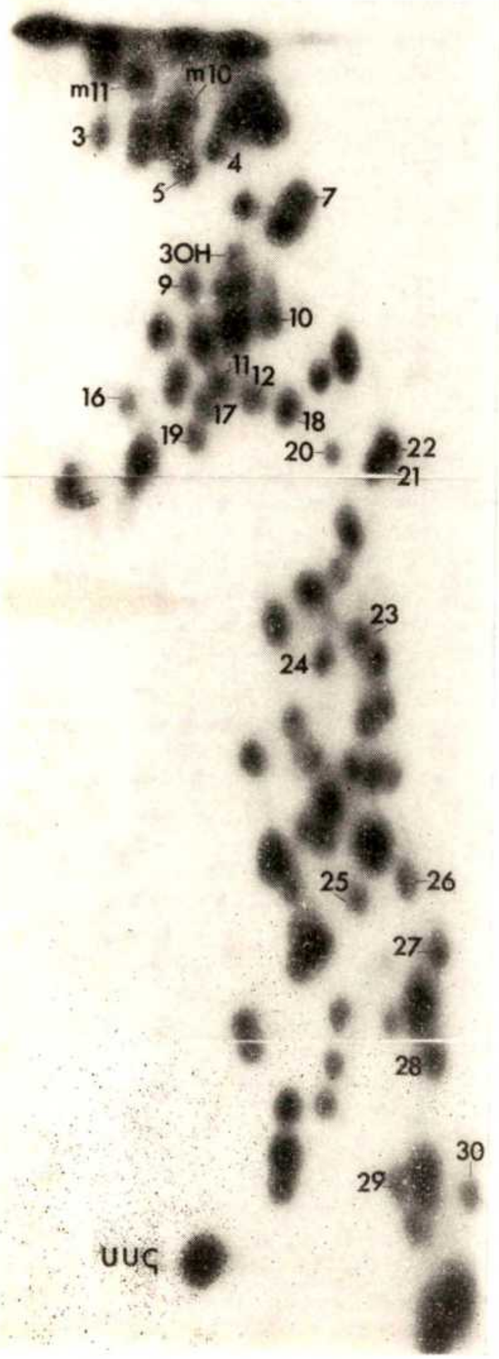

Fig. 1

Fig. 1. Fractionation of a T_1 ribonuclease digest of the 23S RNA. ^{32}P-labelled 23S RNA was prepared from *E. coli* MRE 600 in the way previously described[3]. It was digested with T_1 ribonuclease and bacterial alkaline phosphatase[3,14]. About 0·05 mg of the digest (specific radioactivity, 6 mCi/mg) was fractionated by high voltage electrophoresis on cellulose acetate (5 per cent acetic acid—7 M urea, direction right to left) and then on DEAE-paper (7 per cent formic acid, top to bottom), in the way described by Sanger *et al.*[12]. To study some of the larger oligonucleotides it was necessary to carry out electrophoresis for a long time in the second dimension (with the oligonucleotide UUG migrating about 75 cm from the origin) to obtain satisfactory separations of the large numbers of products. From their appearances on the fingerprints, we thought a considerable number of the spots were likely to be pure. From these we selected a group of spots at random, to examine further. Nucleotide sequence analysis of these products was carried out using the techniques described by Sanger and his colleagues[12,14]. The products resulting from treatment of the spots with pancreatic ribonuclease and venom phosphodiesterase were determined. In most instances it was necessary also to carry out partial digestion with venom phosphodiesterase to determine the complete nucleotide sequence. We used the following conditions: 0·01 ml. of a venom phosphodiesterase solution (0·02 mg/ml. enzyme; 0·02 M Tris, *p*H 8·5; 0·01 M Mg^{2+}); digestion for 10 min at room temperature. The products were fractionated on DEAE-paper at *p*H 1·9. These products were characterized by hydrolysis with pancreatic ribonuclease, venom phosphodiesterase or alkali. Those oligonucleotides which were incompletely analysed generally did not digest well in these conditions. The molar ratios of the oligonucleotides were determined by cutting out the spots and determining their radioactivities by liquid scintillation counting. Two well resolved fingerprints derived from different preparations of the 23S RNA were used for this. The mean values are reported in Table 1. The differences between the two determinations were generally less than 10 per cent.

Our quantitative studies show that in T_1 ribonuclease digests the methylated products m10 and m11 arise in twice the amounts of many of the other oligonucleotides, including the presumed 3′-terminal fragment (3OH). Two other oligonucleotides (3 and 24) are present in similar quantities to the methylated products, and spot 15 is probably also released in equimolar amounts with these products. Spots 5 and 18 display a sequence homology of ten nucleotides, interrupted by a single pyrimidine change. The chance of encountering this in such a study is somewhat less than 1 : 1,000 (see footnote to Table 1). Spots 20, 27 and 28 occur in small amounts relative to the other products, perhaps because of point ambiguities within the molecule at these positions.

Table 1. NUCLEOTIDE SEQUENCES AND SUGGESTED MOLAR FREQUENCIES OF SOME T_1 RIBONUCLEASE PRODUCTS FROM THE 23S RIBOSOMAL RNA

Spot	Sequence	Observed molar ratio	Suggested molar frequency

* The sequences of products m10, m11 and 3OH have been previously reported[2,4].

The observed molar ratios were expressed relative to spot m10 being present twice within the 23S RNA (see text). An octanucleotide homology exists between spots 5 and 18. The octanucleotide sequences of 3 and 24 are probably present twice. The probability of encountering an octanucleotide repetition in a study of this size may be roughly calculated in the following way: the completely determined sequences (Nos. 3–30) encompass fifty octanucleotide runs, that is about 1/1,250 of the total number of possible octanucleotides, and therefore the chance of obtaining a repetition of an octanucleotide sequence will be less than 1/1,000.

The simplest explanation of these findings would be that most of the sequences examined here occur once within the 23S RNA, but the methylated sequences and some others are repeated. This explanation is compatible with earlier findings that the methylated sequences are duplicated in the molecule[2,3] and also with more recent measurements of the amount of methylated nucleotides released by alkaline hydrolysis of ^{32}P-labelled 23S RNA (ref. 13). If this model is correct, then the 23S RNA has some properties in common with the 16S RNA. The latter is also predominantly homogeneous, and contains a greater amount of sequence repetition than would be expected on a random basis.

Alternative explanations of these results would invoke extensive heterogeneity of the 23S RNA. For example, the methylated sequences and certain others would be postulated to be present once each in all 23S RNA molecules, and arise in molar amounts in enzymatic digests, but other sequences would differ between the hypothetical sub-species of the 23S RNA, and therefore be encountered in sub-molar amounts. This explanation is not compatible with quantitative findings on the level of methylation of the 23S RNA, but nevertheless it cannot be entirely ruled out in the absence of more extensive sequence analysis of this molecule.

Temperature Sensitive Alteration of 30S Subunits demonstrated by *in vitro* Reassociation of Functional Ribosomes

RECONSTITUTED ribosomes which lack some ribosomal proteins were found to be inactive in catalysing poly-U-dependent phenylalanine incorporation[1]. A similar result was previously reported resulting from an alteration of the 50S ribosomal subunit by a temperature sensitive mutation[2]. Temperature sensitive mutants of *Escherichia coli* K12 defective in protein synthesis have been isolated in this laboratory, and I report here, for the first time, that mutant strain C1716 was much less active in poly-U-dependent polyphenylalanine synthesis due to an alteration of the 30S ribosomal subunit.

Mutant C1716 was isolated from the cells surviving treatment with 100 µg/ml. streptomycin for 1 h at 42° C. One might expect to find streptomycin resistant mutants of the kind that have already been extensively studied. One also expects to isolate bacteria that grow at low temperature but are sensitive to streptomycin, that are not killed by streptomycin at elevated temperature, and that do not grow at high temperature with or without streptomycin. On these assumptions, *E. coli*, K12 strain HfrH 3000 thy$^-$ met$^-$ growing exponentially at 35° C in L-broth[3] was exposed to N-methyl-N′-nitro-N-nitrosoguanidine, 100 µg/ml. for 40 min at 35° C. Cells were washed twice and grown for three generations at 25° C. The culture was then diluted, and the cells were grown at 43° C for 1 h in the presence of streptomycin sulphate, 100 µg/ml. Using the replica plating technique, 270 temperature sensitive (*ts*) mutants were isolated from a total of 5,000 clones examined. More *ts* mutants were isolated than I could investigate. Four out of thirty-six *ts* strains tested for poly-U-directed polyphenylalanine synthesis were defective at 42° C. One *ts* strain showed a mutation at the streptomycin locus[4].

Strain C1716 grew at 30° C, but growth was immediately arrested when the temperature was raised to 42° C. A temperature shift to 42° C caused protein and RNA synthesis in the intact cells to stop. *In vitro* incorporation of phenylalanine directed by poly-U was also inactive at 42° C with the extracts obtained from the mutant. Kinetics of phenylalanine incorporation showed that the inhibition of peptide synthesis started within 5 min of incubation at 42° C, whereas the incorporation at 30° C continued for 30 min (Fig. 1).

Table 1. POLY-U-DEPENDENT PHENYLALANINE INCORPORATION BY THE WILD TYPE STRAIN AND C1716

Ribosomes	Concentration of Mg^{2+} (mM)	30° C (c.p.m.)	42° C (c.p.m.)	Ratio of 42° C/30° C
HfrH 3000	10	2,310	1,050	0·32
C1716		2,010	192	0·095
HfrH 3000	15	5,140	5,760	1·1
C1716		3,960	704	0·18

The ribosomes and the supernatant fractions were isolated by the method of Nirenberg and Matthaei[5]. The assay system contained 0·1 mole Tris HCl, *p*H 7·8, 20 mmoles NH_4Cl, 10 or 15 mmoles magnesium acetate, 1 mmole ATP, 0·6 mmoles GTP, 1·8 mmoles mercaptoethanol, 0·2 mmole unlabelled amino-acids minus phenylalanine, 4 mmoles phosphoenol pyruvate, 20 µg/ml. pyruvate kinase, 0·5 µCi/ml. of ^{14}C-phenylalanine (100 mCi/mmole, New England Nuclear Co.), 100 µg/ml. *E. coli* K12 *t*RNA (Calbiochem), 100 µg/ml. poly-U (Sigma Co.), 2 $A_{260\ nm}$ units of ribosomes and 120 µg of the supernatant fraction protein of the wild type cells in a total volume of 0·2 ml. Reaction mixtures were incubated at 30° C and 42° C for 10 min. The reaction was stopped by addition of 3 ml. of 5 per cent trichloroacetic acid. The precipitate was heated in a 90° C water bath for 15 min, brought to room temperature and filtered on a glass filter GF/C (Whatman). The filter was dried, and the radioactivity was measured in a Packard liquid scintillation counter in the toluene-omnifluor (New England Nuclear Co.) system.

Experiments, comparing the ribosomes isolated from the wild type strain and the mutant, were performed using the soluble enzyme fraction obtained from the wild type strain. Ribosomes from strain C1716 were much less active in catalysing poly-U-dependent polyphenylalanine synthesis than ribosomes from the wild type at 42° C (Table 1). The difference between both strains was more drastic at 15 mM magnesium concentration. Even at 30° C, activity of the ribosomes was different when equal amounts of wild type and mutant ribosomes (on an $A_{260\ nm}$ basis) were assayed (Table 1). Other experiments showed that the soluble enzyme fraction from strain C1716 was equivalent to that of the wild type. The data indicate that strain C1716 has a *ts* mutation in the ribosomes. The ribosomes from the mutant were incubated at 55° C for 20 min in buffer to determine whether or not they irreversibly lose the capacity to function in subsequent peptide synthesis. After the heat treatment there was no significant reduction in ribosomal function when tested at 30° C.

Table 2. POLY-U-DEPENDENT-PHENYLALANINE INCORPORATION OF RECONSTITUTED RIBOSOMES

Ribosomes		Radioactivity (c.p.m.) at	
50S	30S	30° C	41° C
W*	—	184	42
M*	—	206	50
—	W	157	60
—	M	67	62
W	W	3,290	1,770
W	M	2,600	296
M	W	3,140	1,980
M	M	2,300	304

The 50S and 30S subunits of ribosomes were prepared by the method of Traub *et al.*[6]. Reaction mixture contained 0·05 moles Tris HCl, *p*H 7·8, 20 mmoles NH_4Cl, 10 mmoles Mg acetate, 1 mmole ATP, 0·6 mmoles GTP, 1·8 mmoles mercaptoethanol, 0·2 mmoles unlabelled amino-acids minus phenylalanine, 4 mmoles phosphoenol pyruvate, 20 µg/ml. pyruvate kinase, 0·75 µCi/ml. of ^{14}C-phenylalanine (100 mCi/mmole), 200 µg/ml. tRNA, 100 µg/ml. of poly-U, 2$A_{260\ nm}$ units of 50S, 1 $A_{260\ nm}$ units of 30S and 70 µg of supernatant fraction protein of wild type cells in a total volume of 0·2 ml. Reaction mixtures were incubated for 20 min at 30° C or 41° C. Detailed procedures are described in Table 1. Data are the average of two separate experiments.

* W indicates subunit obtained from the wild type cells, and M indicates subunit from the mutant cells.

To determine the site of inactivation within the ribosomes the 50S and 30S ribosomal subunits were prepared from C1716 and the wild type strain, and then hybrid 70S ribosomes were reassociated from these 50S and 30S subunits in all combinations (Table 2). Results using these hybrid ribosomes indicated that the source of the 50S ribosomal subunits did not have any influence on polyphenylalanine synthesis. In contrast, ribosomes reassociated from mutant 30S subunits with either wild type or mutant 50S subunits were much less active in poly-U-dependent polyphenylalanine synthesis when compared with the activities of reassociated ribosomes that contained wild type 30S subunits at a restricted temperature.

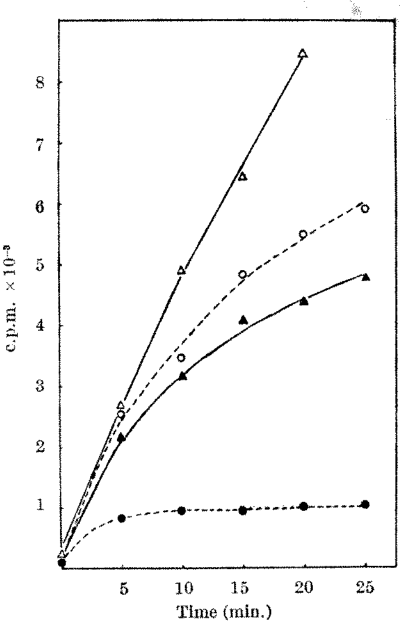

Fig. 1. Kinetics of poly-U-directed phenylalanine incorporation by the wild type and mutant cells extracts. 30S fractions were obtained by the method of Nirenberg and Matthaei[5]. The assay of incorporation was performed as described in Table 1, except that reaction mixtures contained 1 $A_{260\ nm}$ unit of 30S fractions per 0·2 ml. of the reaction mixture instead of ribosomes and soluble enzyme fraction. Open circles indicate incorporation by the mutant extracts at 30° C; closed circles by the mutant at 41° C; open triangles by the wild type at 30° C; closed triangles by the wild type at 41° C.

Thus the mutation in strain C1716 occurred in a cistron that was responsible for the synthesis of one of the 30S ribosomal components and alteration of this cistron caused an inhibition of protein synthesis at high temperature.

Differences in E and S Chains from Isoenzymes of Horse Liver Alcohol Dehydrogenase

THREE isoenzymes of horse liver alcohol dehydrogenase, $LADH_{EE}$, $LADH_{ES}$ and $LADH_{SS}$, are formed by the possible dimeric combinations of two different protein chains, the E-chain and the S-chain[1].

The structures of the two types of chains have been compared[2] and were shown to be similar, suggesting a common genetic origin. Three amino-acid substitutions were then found, all compatible with one-base mutations. This was performed by comparisons chiefly between the EE and ES isoenzymes, for only small amounts of the pure SS form were available. The latter has since been crystallized (Å. Åkeson and G. Lundquist, to be published) and purified in greater amounts. Tryptic digests of ^{14}C-carboxymethylated EE and SS isoenzymes have now been extensively compared by multidimensional "fingerprinting" techniques similar to those used with the ES isoenzyme[2]. The peptide differences can be seen more distinctly with the two homogeneous isoenzymes than with the EE and hybrid ES forms previously compared.

More differences between the two types of chains have been found so that six mutations are now known (Table 1). The first three mutations have been detected previously[2]. Their numerical positions and those of the fourth and fifth mutations are now exactly known from the amino-acid sequence of the E-chain (H. J., submitted for publication). The position of the sixth mutation is still somewhat uncertain, for the structure of this part of the protein chain is not definitely established. The peptide from the S-chain containing the fifth mutation (a basic heptapeptide) is difficult to purify; only a small yield was available. Although sufficient material for complete sequence analysis was not obtained, it was possible to determine the total composition. From this and the electrophoretic charge of the peptide, the mutation in Table 1 is deduced on the assumption that the peptide contains only one substitution. All other mutations have been proved by analyses of both compositions and complete amino-acid sequences of differing peptides. Although five of the mutations are compatible with one-base mutations, the fifth requires a change of two bases.

Table 1. MUTATION SITES

Mutation number	Position along the protein chain	Residue in E-chain	Residue in S-chain
1	17	Glu	Gln
2	94	Thr	Ile
3	101	Arg	Ser
4	110	Phe	Leu
5*	115	Asp	Ser*
6	366†	Glu	Lys

* Based on total composition only (see text).
† Preliminary number.

The six mutations now known render the S-chain more positive than the E-chain by three charged units around neutral *p*H. This explains the electrophoretic properties of the isoenzymes[1] and is in keeping with the differences in *pI*[2] between them. Before, when only the three first mutations were known[2], these facts could not be accounted for.

Of the six mutations, four are closely situated at the region around position number 100 of the chains. In addition, these four substitutions are for both smaller and more hydrophobic residues in the S-chain when compared with the similar portions of the E-chain. This fact and the known difference in substrate specificity between the chains (the S-chain is active towards steroid substrates but the E-chain is not[1]) might suggest that the mutation-rich region around position 100 is close to the substrate binding site. The need for more space and hydrophobicity at this site of the S-chain, as compared with that of the E-chain, might then possibly be explained by these mutations, although changes in the three-dimensional folding of the chains are, of course, alternative explanations.

I thank Professor H. Theorell and Dr Å. Åkeson for help and interest and for supplying the pure isoenzymes. This work was supported by a grant from the Swedish Medical Research Council to Professor Theorell.

Size-specific Metal Complexing Sites in Native Collagen

THERE is evidence that metal ions are involved, directly and indirectly, in the structure and function of the collagens[1–11]. The direct interactions between collagen proteins and metal ions must be elucidated in order to understand the roles of these ions in connective tissues. One approach is to study the metal binding properties of relatively intact collagen matrices in model systems consisting of water solutions of several ionic salts. Previous experiments have involved the binding of a few ions to purified reconstituted calf-skin collagen[12], egg shell matrix[13], gelatine[14] and bivalent amino-acids[15].

We report here the results of experiments in which whole sections of decalcified bone matrix and tendon were exposed to twenty-four metallic ions.

Table 1. EXPERIMENTAL CONDITIONS DURING EXPOSURE TO IONIC SOLUTIONS

	Experiment 1	Experiment 2
*p*H	1+6·3 2+6·4 3+3·5 Adjusted NH_4OH	5·4; Adjusted NaOH
Ionic strength	0·011–0·016 M	0·16 M
Indiv. ion conc.	0·3–3·0 mM	4·0 mM
Sample/solution (w/v)	0·05 g/100 ml.	0·2 g/100 ml.
Exposure	3 days	2 days
Ions 1^+	Li, Na, Ag, K, Rb, Cs	Li, Na, Ag, K, Rb, Cs
2^+	Be, Mg, Sr, Ba, Mn, Zn, Cu, Cd, Hg, Pb	Be, Mg, Ca, Sr, Ba, Zn, Cu, Cd, Co, Ni, Pb
3^+	Al, Ga, Cr, Fe, Bi	

Small sections of normal human tibial cortex and human Achilles tendon were demineralized for 5 days (5 per cent formic acid, 25° C), washed and stored under distilled deionized water until use. Other tendon sections were only washed. The samples were immersed in compound equimolar nitrate salt solutions at room temperature (Table 1), and washed in three changes of water for 1 h. In the first experiment, demineralized bone and washed tendon (in the same vessel) were exposed to compound solutions of either 1^+, 2^+ or 3^+ ions. Demineralized tendon was included in the divalent ion solution. In experiment 2, demineralized bone and demineralized tendon (in separate vessels) were exposed to solutions containing many 1^+ and 2^+ ions mixed together. Relative uptakes were determined by measuring the resulting metal concentrations in the substrates, using d.c. arc emission spectroscopy[8,9]. Control concentrations in unexposed tissues were generally well below induced concentrations. Comparison of preliminary uptake with time showed that equilibrium was reached within 12 h of exposure.

Table 2. CONCENTRATIONS OF IONS BOUND TO COLLAGEN SAMPLES

		Experiment 1			Experiment 2	
		Demin. bone	Demin. tendon	Washed tendon	Demin. bone	Demin. tendon

– Indicates less than 0·1 μmoles/g of metal in dry tissue.
+ Indicates 0·1–10 μmoles/g of metal in dry tissue.
+ + Indicates 10–30 μmoles/g of metal in dry tissue.
+ + + Indicates 30–50 μmoles/g of metal in dry tissue.
+ + + + Indicates 50 or more μmoles/g of metal in dry tissue.

The concentrations of metal ions bound to the substrates are outlined in Table 2. Differences in Pb^{2+} and 3^+ ion uptakes in the first experiment may reflect structural or conformational differences between the bone and tendon collagen, as prepared here. When plotted as a function of the ionic radii of the metal ions[16], the preferentially bound ions fell into at least two size categories, 0·65 – 0·75 Å and 1·2 – 1·3 Å (Fig. 1). These categories were to a certain extent independent of the specific ions involved, the charges on the ions, and the experimental conditions used. It may also be significant that the "preferred sizes" differed approximately by a multiple of two. To our knowledge, these are the first such size-specific interactions observed for collagen matrices.

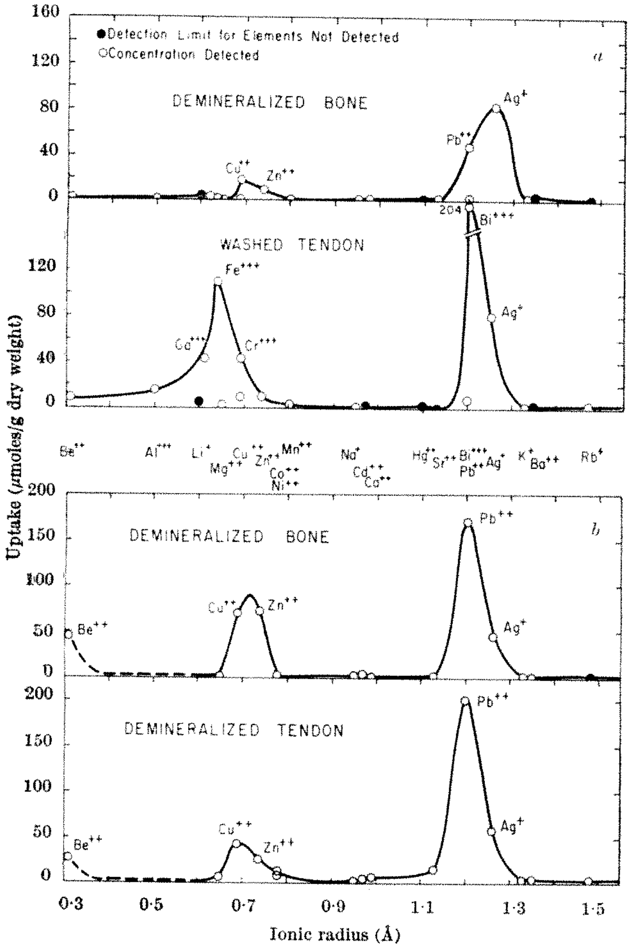

Fig. 1. The ion uptake (μmoles/g dry weight of tissue) as a function of ionic radius for (a) demineralized bone and washed tendon in experiment 1, and (b) demineralized bone and demineralized tendon in experiment 2. The uptake of divalent ions in demineralized tendon in experiment 1 (not shown) was identical to the results for washed tendon shown above. Trivalent ions were omitted in experiment 2 to maintain the pH of the hetero-ionic solutions above 5. The two preferred size regions are evident as are differences between the ion selectivities of bone and tendon matrices in experiment 1.

For chelate complexes involving a given donor and several different metal ions, it has been shown that the logs of the formation constants are a linear function of the total ionization potentials of the ions[17]. Furthermore, in the conditions of a large excess of several metal ions in equimolar concentrations, the log of the metal ion concentration measured in the substrate should also be proportional to the ionization potential[18] if a coordination complex is formed.

Thus the general linearity in Figs. 2 and 3 is strong evidence for coordination bonding (or chelation) in these collagen matrices, and that most of the ions were bound to a single type of donor group. Many

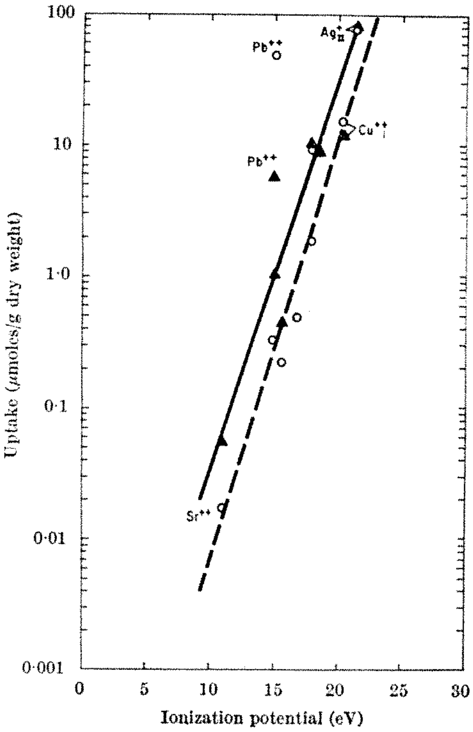

Fig. 2. The ion uptakes in experiment 1 (μmoles/g dry weight of tissue) plotted against the total ionization potentials of the ions on a semi-log scale. The trivalent data are omitted because of the extremely different experimental conditions obtaining in that part of the experiment. The divalent uptakes in decalcified tendon (not shown) were similar to those for washed tendon. The second ionization potential of Ag was used in this plot. The concentrations bound to the tendon matrix were higher than that for demineralized bone matrix, although the slopes were nearly identical. The Pb concentrations clearly stray from the rest. ○, Decalcified bones; ▲, washed tendon.

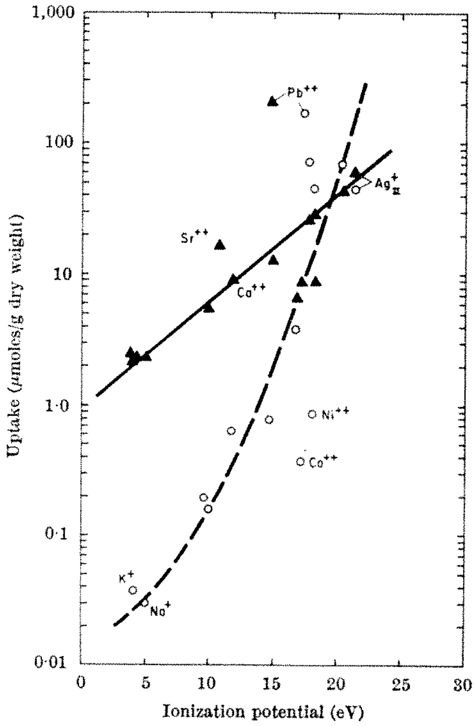

Fig. 3. The ion uptakes in experiment 2 (μmoles/g dry weight of tissue) plotted against the total ionization potentials on a semi-log scale. Ag is plotted using its second ionization potential. As in Fig. 2, the tendon matrix bound many ions more avidly than demineralized bone, but with a considerably smaller slope. The slope for decalcified bone is generally similar to that in the previous experiment; the considerable scatter and curvature in this experiment probably reflects the higher ionic strength and lower pH used. The Pb, Co and Ni uptakes stray from the bulk of the data. ○, Decalcified bone; ▲, decalcified tendon.

of the strongly bound ions (1+ and 2+) readily coordinate to donor nitrogens[19,20], so the bonding may be primarily to uncharged amino, imidazole or guanidino groups in the substrates, and may be largely ion-polar or covalent in character[20]. Although titratable, the charged carboxyls are only partially available for binding in native collagen due to internal charge compensation at medium *p*H[21]. The binding of trivalent ions in experiment 1 at low *p*H, however, may have been to the latter site[22].

Others have suggested that metallic coordination complex formation in cartilage[23], elastin[11,24] and egg shell matrix[13] is important in the primary calcification process. Similar complexes may be involved in the calcification (or lack of it) in bone and tendon matrices.

Genetic Control of Deficiencies in γG Subclasses observed among Families with Hypogammaglobulinaemia

SEVERAL research units have studied the genetic mechanisms controlling the synthesis of immunoglobulins and its alteration in hypogammaglobulinaemia. Fudenberg *et al.*[1] investigated Gm and Inv groups in families with agammaglobulinaemia, and suggested the involvement of two genes in the synthesis of an immunoglobulin: one controlling the synthesis of the heavy chains, the other that of the light chains. Burtin *et al.*[2] applied the same principle in their studies on "non sex-linked atypic hypogammaglobulinaemia", and postulated the existence of abnormal alleles leading to an impaired synthesis of the heavy chains of one or several immunoglobulins.

Since then, the heavy chains of γG have been subdivided into four subclasses: γG1, γG2, γG3 and γG4[3,4]. The Gm factors were located on these subclasses as follows: the γG1 carry Gm factors 1, 2, 4, 8, 9, 17, 18 and 22; the γG2 carry factors Gm 8 and 23. The Gm factors 5, 6, 10, 11, 14, 15, 16 and 21 are located on the heavy γG3 chains. So far the γG4 have not been assigned a genetic marker. Independent genetic control of the synthesis of each γG subclass could be determined by a study of these Gm groups in families with one or several cases of immunoglobulin deficiency. Previously[5] we have shown a selective lack of some subclasses of γG in apparently healthy members of a family with two cases of

* Weakened inhibiting power as compared with the control serum.

ataxia telangiectasia. We report here the determination of Gm phenotypes in five families, one or more members of each having a deficit in one or several immunoglobulins. We measured the Gm factors 1, 2, 4, 5, 8, 17 and 21 and Inv factors 1 and 2 by their inhibiting power, and the concentration of γG, γA and γM globulins by the Mancini method.

The first family (B 492) was that of a 39 year old woman who in 1967 developed diarrhoea, arthralgia, furunculosis and tuberculous lymphadenitis. Her serum and the sera of nineteen relatives were studied. Table 1 gives the Gm titres and the levels of immunoglobulins in these sera. It shows that the proband is agammaglobulinaemic, and that her mother has unusually small amounts of the three immunoglobulins. Both have a weak expression of all Gm groups. In other members of the family, the inhibiting power of some Gm factors is clearly abnormally low. The results of the study on Gm factors indicate that the γG2 and γG3 are the ones most often decreased. This deficiency is genetically transmitted, as is shown in Table 1. It exists in the men II*b* and II*c* and their respective sons III*a* and III*d*. It contrasts with the value of total γG which is normal or only slightly lowered in these sera. This could be explained by the relatively small amounts of γG2 and γG3, which represent only 15 per cent and 10 per cent respectively of the total γG.

In each of the four other families we investigated, the Gm allotypes indicated a deficit in one or more γG subclasses in the proband's serum and in some clinically normal relatives. They have immunoglobulins which are quantitatively normal, or slightly deficient in one or more classes. These observations favour strongly the hypothesis of a genetic mechanism of "non sex-linked atypic hypogammaglobulinaemia".

Does this genetic mechanism involve structural or regulatory genes ? The observation of unusual phenotypes in some members of these families could favour the first alternative, as suggested by Yount *et al.*[6], who made the same statement. These phenotypes are very rare in Caucasians, for example, Gm (1, 2, −4, 5, −8, 17, 21) or Gm (1, 2, −4, 5, −8, 17, −21). Moreover, they could lead to an exclusion of paternity or maternity. For example, in family U 204 (Table 2), child II–3 has the Gm (1, 17, 21) group inherited from the father, and the Gm (4, 5, 8) group which should have come from the maternal chromosome. But the mother has only the phenotype Gm (5, 8) and lacks Gm (4). Does that mean exclusion of maternity ?

The other alternative is that these abnormal phenotypes correspond to an abnormally weak expression of normal structure genes, arising from a lesion of regulatory genes. Let us suppose the existence of regulatory genes $G1$, $G2$, $G3$, controlling the synthesis of the $\gamma 1$, $\gamma 2$, $\gamma 3$ chains. The presence of $g1$, $g2$, $g3$ alleles in simple or double doses would result in partial or total inhibition of the expression of structural genes. In family U 204, the mother having a deficit in Gm (5) and (8), and absence of Gm (4) and (21), would carry abnormal $g1$, $g2$ and $g3$ alleles. She is probably heterozygous, because her child II–3 has a normal phenotype. The decrease of Gm (4, 5, 8) in children II–1 and II–2, contrasting with a normal level of these factors in their father, could be explained by the heterozygous state $G1g1$, $G2g2$, $G3g3$ in the children. Accordingly, the father would have normal regulatory genes. Thus the transmission of regulatory genes would be independent from that of structural genes. It has not previously been possible to establish a selective deficit of γG4 because of the lack of a genetic marker for this subclass.

In conclusion, we have demonstrated the existence of independent genetic mechanisms controlling the synthesis of the heavy chains of each γG subclass. These mechanisms are altered in patients with non sex-linked hypogammaglobulinaemia, and in some of their relatives. The deficit may or may not be revealed by a decrease in total γG. A lesion of the regulatory rather than the structural genes seems to be responsible for this phenomenon.

Demonstration in Sarcoma Patients of Anti-tumour Antibodies which Fix Only Human Complement

SPECIFIC anti-tumour antibodies have now been demonstrated in human sera using several different serological techniques[1-5]. Except in the case of Burkitt's lymphoma[6,7], however, specific anti-tumour antibodies have not been consistently detectable with the complement fixation test. Our recent immunofluorescence studies have demonstrated specific antisarcoma antibody in the serum of patients with this disease[8]. In attempting to detect these antisarcoma antibodies by complement fixation, it was noted that they could be demonstrated only if cells derived from cultured human sarcoma cells were used as antigen and fresh human serum was used as a source of complement. This report describes the conditions necessary for the demonstration of these anti-tumour antibodies in human sera.

The complement fixation test was a modification of the microtitre technique described by Sever[9]. Isotonic vernal buffered saline (pH 7·4) was used as diluent throughout. The haemolytic system was a 0·5 per cent suspension of washed sheep red blood cells (SRBC) sensitized with an equal volume of rabbit anti-SRBC haemolysin, 1 : 2,000, at 37° C for 20 min. To ensure that all sera tested as sources of complement contained equivalent amounts of complement, dilutions of each were made so that two 100 per cent haemolytic units were contained in each 0·025 ml. of serum.

A human liposarcoma (SA-1) cell line was used as antigen[10,11]. Cells were thrice frozen at −190° C and thawed at 37° C. The suspension was then sonicated with a probe sonicator for 20 s/ml. of material and stored at −190° C. Four units of antigen were used in each test as determined by a box titration against a high titre serum from a patient with osteosarcoma which had previously been demonstrated to contain antibody by immunofluorescence.

Antigen prepared from tissue culture cells, antibody (sarcoma patient's heat inactivated serum) and two units of complement were added to the microplates, sealed and incubated at 37° C for 1 h. The haemolytic system was then added and incubated for an additional hour at 37° C. The plates were centrifuged and the test scored on a scale from 0 to 4, the scores corresponding to the size of the red-cell button and the amount of complement fixed. Each test included a complement titration, a complement titration in the presence of antigen, and a control for anti-complementary activity of the serum and antigen.

Table 1. THE ABILITY OF HUMAN ANTISARCOMA ANTIBODIES TO FIX VARIOUS TYPES OF COMPLEMENT

Source of complement	Serum dilution containing two units of complement/0·025 ml.	Antisarcoma titre* (1)	(2)	(3)
Rabbit A	1/8	0	0	0
Rabbit B	1/9	0	0	0
Rabbit C	1/9·5	0	0	0
Rabbit pooled (6)	1/8	0	0	0
Guinea-pig pooled (6)	1/80	0	0	0
Gelada baboon pooled (3)	1/11	0	0	0
Baboon (Papio) pooled (3)	1/8	—	—	—
Chimpanzee pooled (3)	1/5	—	—	—
Human sera AB^1 +	1/8	0	0	0
Human sera AB^2 +	1/10	0	0	0
Human sera A +	1/9	1/4	1/16	1/8
Human sera B +	1/8·5	1/4	1/8	1/4
Human sera C −	1/8	1/8	1/16	1/16
Pooled human sera (8)	1/8·5	1/4	1/8	1/8
Human cord sera pooled (10)	1/8	1/32	1/128	1/64

* Antigen was a 1 : 8 dilution of a 20 per cent suspension of SA-1 (liposarcoma) cells. The sera were from patients with (1) chondrosarcoma; (2) fibrosarcoma and (3) osteosarcoma. Sera marked "—" were unsuitable as a source of complement because they contained natural anti-human antibody.

Various types of fresh animal and human sera were examined as a potential source of complement. An aliquot of each serum was first heat-inactivated and tested for antibody activity against the SA-1 liposarcoma antigen using human cord serum as a complement source. If no antibody was detected, dilutions of each serum were made and complement was titrated at each dilution. The anti-sarcoma antibody titres of patients with skeletal and soft tissue sarcomas are listed in Table 1 along with the source of complement used. Pooled samples of Papio (baboon) and chimpanzee serum were found to react with HeLa and SA-1 antigen complement to a titre of 1/8 and therefore were not useful as a source of complement. No antisarcoma antibody was detectable in sera from rabbit, guinea-pig or gelada baboon (*Theropithecus gelada*), but each serum was found to be ineffective as a source of complement for the human sarcoma antigen–antibody system. When individual human sera with no detectable anti-sarcoma activity were tested, a considerable variation in their ability to act as sources of complement was noted. In most cases some complement fixation was evident. Pooled human umbilical cord serum was uniformly the best source of complement for the detection of these antisarcoma antibodies, for it never contained natural antibody to the antigen and always gave four to eight-fold higher titres than other types of human complement.

Preliminary studies also demonstrated the presence of antibodies in the sera of melanoma patients which react with a tissue culture cell line derived from a human malignant melanoma. These seem to be similar to the antisarcoma antibodies in that they, too, only fix human complement. Thus the complement fixation test using tissue culture cells from malignant tumours as antigen and human serum as a complement source may be valuable for the demonstration of anti-tumour antibodies in human sera.

Immunoglobulin G as Possible Precursor of Chemotactic Factor

FROM the site of an Arthus reaction or burn lesion, a chemical factor has been isolated ("leucoegressin") that causes the accumulation of polymorphonuclear leucocytes[1,2]. A possible precursor has, moreover, been located in the γ_2-globulin fraction of normal rabbit serum[3], because when six protein fractions such as albumin and α_1, α_2, β_1, β_2 (or γ_1) and γ_2-globulin fractions—obtained from normal rabbit serum by block electrophoresis on a 'Pevikon C-870' column—were each incubated with a purified SH-dependent protease[4,5] from inflammatory tissue, the γ_2-globulin fraction became strongly chemotactic for polymorphonuclear leucocytes. We now are able to report further information on its precursor. We have evidence that immunoglobulin G (IgG) gives rise to a chemotactic factor during these inflammatory processes, and it seems that the chemotactic factor has antigenic sites in common with IgG and can in fact be generated by the enzymatic treatment of fractionated IgG *in vitro*.

Table 1. EFFECT OF ANTI-IgG-ANTIBODY ON CHEMOTACTIC FACTOR

Samples (in lower compartment)	No. of PMNs migrated (per 5 fields)
Chemotactic factor + phosphate buffer	211
Anti-IgG-antibody + phosphate buffer	48
Chemotactic factor + anti-IgG-antibody (equal volumes)	4
Phosphate buffer	26

The materials used were chemotactic factor (100 μg in phosphate buffer, 0·067 M, *p*H 7·4) purified with CM-Sephadex rechromatography; and goat-IgG fraction (500 μg) precipitated at 33 per cent saturation with ammonium sulphate. All samples were filtered with 'Millipore' filter (pore size 0·3 μm) after the reaction.

Antisera against rabbit serum and rabbit IgG were prepared in goats with complete Freund's adjuvant. The sera were collected after several immunizations. Rabbit chemotactic factor was purified as already reported[1,2]. Agar immunoelectrophoresis (*p*H 8·2, *I* 0·05) gave a single precipitin line with goat anti-rabbit serum (Fig. 1). By using goat antiserum against rabbit IgG, partial identity of the chemotactic factor and IgG was revealed. When goat antibody fraction against rabbit IgG was reacted with chemotactic factor at 37° C for 30 min and the absorption product filtered on a 'Millipore' filter (0·3 μm) the chemotactic activity disappeared from the fluid phase (Table 1).

IgG was separated in the cold from normal rabbit serum according to the method of Kapusta and Halberstam[6], using sodium sulphate precipitation and DEAE-cellulose column chromatography. The isolated fraction was homogeneous as judged by immunoelectrophoresis against goat anti-rabbit serum. This IgG had no chemotactic activity, but after treatment with the purified inflammatory SH-dependent protease[4,5] exhibited chemotactic activity on polymorphonuclear leucocytes, as demonstrated by *in vitro* assay according to Boyden's

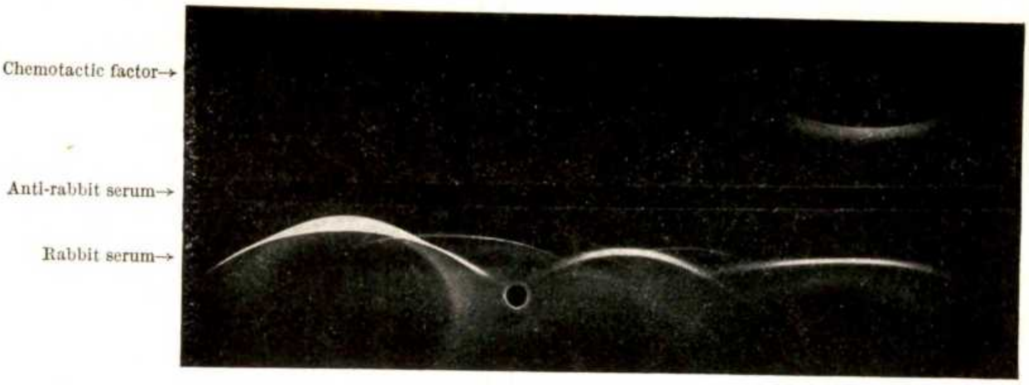

Fig. 1. Agar immunoelectrophoresis of chemotactic factor (pH 8·2, I 0·05, veronal-HCl buffer). The anode is to the right.

method[7] using 'Millipore' filters (DAWP013; pore size 0·65 μm) and a modified chamber containing two 1 ml. compartments. The test samples, in 0·067 M phosphate buffer (pH 7·4), were placed in the lower compartment; the 'Millipore' filter was placed on it, and rabbit polymorphonuclear leucocytes—collected from the peritoneal cavity by Hirsch's method[8] and suspended in Gey's buffered solution containing 2 per cent human serum albumin (pH 7·4)—were poured into the upper compartment. The cells that had passed through the filter were stained with haematoxylin and counted over five microscopic fields (10 × 40); the total counts were recorded (Table 2).

Table 2. ACTIVATION OF IgG WITH THE INFLAMMATORY SH-DEPENDENT PROTEASE (INFLAMMATORY PROTEASE)

Samples (in lower compartment)	No. of PMNs migrated (per 5 fields)
Rabbit IgG (100 μg) + cysteine (10^{-3} M) + inflammatory protease*	449
Rabbit IgG + cysteine + phosphate buffer	24
Cysteine + inflammatory protease	25
Phosphate buffer	18

* 0·02 absorbance units at 276 nm, estimated by the casein digestion method of Kunitz[5,6].

On the basis of these results, we suggest that the precursor of an inflammatory SH-dependent protease is activated in the process of inflammation which follows an antigen–antibody reaction or thermal trauma[1,9-12]. After the increase in vascular permeability has occurred[13-17], this SH-dependent protease converts the exuded IgG molecule to the chemotactic factor which causes the migration of polymorphonuclear leucocytes to the inflammatory lesion. Thus besides the well known specific part as antibody, the IgG molecule may play an immunologically non-specific part as the precursor of a chemotactic factor in inflammation.

Other species of immunoglobulin in the normal rabbit serum were present in amounts too small for the present assay, but we are performing the same type of experiment using IgG and other immunoglobulins of human serum.

We thank Dr M. Koono for a supply of purified inflammatory SH-dependent protease. This work was in part supported by grants from the Education Ministry of Japan.

Effect of Antilymphocytic Serum on the Appearance of Reticular Neoplasms in SJL/J Mice

IT has been shown that BALB/c mice infected with Moloney leukaemogenic virus develop a higher incidence of leukaemias and lymphomas, after a shorter latent period, when they are treated with antilymphocytic serum (ALS) than in the absence of ALS[1,2]. We therefore considered it of interest to examine the effects of ALS on a strain of mice in which lymphomas occur naturally without infection by any exogenous virus. Mice of the strain SJL/J spontaneously develop a high incidence of reticular neoplasms[3-5], which are of the pleiomorphic type *B* described by Dunn[6]. In untreated mice, neoplasms begin to appear when they are about 1 year old and the cumulative incidence before death is over 70 per cent.

ALS was raised by two intravenous injections of 10^9 SJL/J or CBA thymus cells into New Zealand rabbits[7]. In some experiments the active immunoglobulin fraction (ALG) was prepared[8]. Sera were de-complemented at 56° C for 30 min and absorbed with SJL/J erythrocytes before use. Controls received normal rabbit serum (NRS) or the IgG fraction prepared from it (NRG). In one experiment ALS or NRS was administered to SJL/J mice aged 4–6 weeks. At least three subcutaneous injections were given, and animals were killed when aged 27–30 weeks for autopsy. Of eleven survivors receiving ALS, eight showed histological evidence of reticular neoplasia, with distortion of the normal structure of lymph nodes and spleen and proliferation of plasma cells, pleiomorphic lymphoid cells and reticulum cells. None of six controls that had received NRS examined histologically showed signs of neoplasia. This difference is significant ($P < 0·01$).

In a second experiment, newborn SJL/J mice were made tolerant to normal rabbit IgG[1] before receiving eight injections at twice-weekly intervals of 1 mg ALG or NRG. Two mice receiving ALG died with gross neoplasms before the thirtieth week, at which time all survivors were killed for autopsy. Of nine mice receiving ALG, seven had histological evidence of reticular neoplasia, as previously described, whereas none of seven survivors of the group receiving NRG showed signs of neoplasia. This difference is again statistically significant ($P < 0\cdot01$). Two of three attempts to transplant the neoplasms in syngeneic recipients were successful.

These results show that treatment with ALS or ALG shortens the latent period for appearance of reticular neoplasms in SJL/J mice. The most likely explanation seems to be suppression by ALS of an immunological surveillance mechanism which normally retards the appearance of malignancy in this strain of mice. It is not yet clear whether an oncogenic virus plays a major part in this system, but SJL/J tumours show individual antigenicity when transplanted into syngeneic recipients[9], and they may well provoke an immune response in the autochthonous host. Possibly the proliferative stimulus of ALS to primitive lymphoid cells, or other factors, is also relevant. The potentiation by ALS of a naturally occurring malignancy in mice may perhaps serve as a rather extreme model for the appearance of reticulum-cell sarcomas in some human patients receiving chronic immunosuppressive therapy[10-12].

Effect of Route of Administration of Antilymphocytic Globulin on Skin Allograft Survival in Rats

ADMINISTRATION of antilymphocytic serum (ALS) or globulin (ALG) by subcutaneous[1], intramuscular[2], intraperitoneal[3] or intravenous[4] injection has been shown to prolong survival of allografts in various experimental systems. No data seem to be available, however, concerning the relative effect of administering the same dose of ALG by different routes on a particular graft in one species. We have compared the effect of daily intramuscular, intraperitoneal and intravenous injection, and continuous intravenous infusion, of ALG on skin allograft survival in rats.

Table 1. IMMUNIZATION SCHEDULE OF HORSE TO PRODUCE ALG

Antigen : rat thoracic duct lymphocytes

Day	Cell No. $\times 10^9$	Cell viability (per cent)
0	1·02	93
8	1·50	90
14	1·5	87
22	1·02	89
28	1·16	90
35	1·44	95
50	1·70	98
133	3·26	96
174	1·12	81
335	1·00	85
468	1·36	93

ALS was prepared by immunizing a horse with rat thoracic duct lymphocytes as shown in Table 1. The cells were injected intravenously except for the second dose which was given subcutaneously. Adjuvants were not used. Anti-rat ALG was prepared from serum as previously described[5] and absorbed with rat erythrocytes until the haemagglutinin titre of a 1 g/100 ml. solution was not greater than four. The batch used in the present experiments was from blood collected 3 weeks after the last injection of antigen. The cytotoxic titre^{-1} (50 per cent end point) by the trypan blue method[6], using rat thoracic duct lymphocytes and guinea-pig complement, was 128.

Inbred male hooded rats, approximately six months old, were sub-divided into four groups. All received 1·5 ml. of a 1 g/100 ml. solution of ALG daily for 10 days, but the method of administration to the various groups differed as follows: I, intramuscular injection; II, intraperitoneal injection; III, intravenous injection; IV, continuous intravenous infusion.

Intravenous ALG administration was effected with a variable rate infusion pump (B. Braun, Melsungen, Germany) by the technique of Dalton, Touraine and Wilson[7]. In the case of the "intravenous infusion", ALG was given continuously for 10 days. The pump had a delivery rate of 2·4 ml./24 h, so the daily dose of 1·5 ml. ALG solution was made up to 2·4 ml. with isotonic saline solution. Because ALG deteriorates if left at room temperature, syringes were filled once or twice daily. In the case of the daily "intravenous injection", the pump was regulated to deliver the 1·5 ml. dose of ALG solution in 4 min. Isotonic saline solution alone was then infused continuously (2·4 ml./24 h) to maintain the patency of the intravascular catheters. A fifth group of similar rats which were given no ALG (the controls) were infused intravenously with 2·4 ml./24 h of isotonic saline.

The rats were grafted on the third day of ALG administration with split skin from adult male rats of an inbred Wistar strain[8]. The protective dressing over the graft was removed after 7 days. The two rat strains have been maintained in this department for many years by brother–sister mating, and the survival time of Wistar skin allografts to untreated hooded rats not subjected to the technique of continuous intravenous infusion is 8 days[3]. Rats were killed when their skin grafts were completely rejected; and their kidneys were prepared for histological examination.

Table 2. SURVIVAL TIME OF SKIN GRAFTS IN RATS GIVEN THE SAME DOSE OF ALG BY FOUR DIFFERENT METHODS

Group	Treatment	Skin graft survival individual rats (days)	Mean (days)
I	Intramuscular injection	10, 10, 11, 11, 11, 11, 11,	11
II	Intraperitoneal injection	10, 10, 11, 11, 11, 11, 22	12
III	Intravenous injection	17, 18, 23, 23, 31, 32, 77	32 (24)*
IV	Intravenous infusion	17, 21†, 22, 26, 28, 31, 33	25
V	Controls	8, 8, 8, 9, 9, 11, 11	9

* Mean excluding rat with atypical graft survival time of 77 days.

† Rat died although graft was not rejected.

By Student's *t* test, the statistical significances of the differences between the group means were as follows: I and II, not significant; I and II combined : III*, $P < 0\cdot001$; I and II combined : IV, $P < 0\cdot001$; III* : IV, not significant.

The results are shown in Table 2. It can be seen that skin graft survival was significantly longer when ALG was administered intravenously than when it was injected intramuscularly or intraperitoneally. The skin graft survival of one rat in group III was exceptionally long.

If this apparently atypical result is excluded from the group mean, there is no significant difference between the mean graft survival time when ALG was given daily by intravenous injection (group III) or by continuous infusion (group IV). No abnormality was detected in sections of kidney examined by light microscopy.

The greater effectiveness of ALG given intravenously is consistent with the view[9] that its immunosuppressive effect is mainly to be attributed to its action on circulating small lymphocytes. Possibly, when given by other routes, some of the antibody is fixed to tissue at the site of injection and fails to reach the circulation. Further evidence on this point, and an explanation of the lack of difference between the results of a single intravenous injection of ALG and continuous intravenous infusion, might be obtained by studying the residual antilymphocytic activity of serum obtained from animals bled at intervals after injection of ALG. Experiments along these lines are in progress.

From the point of view of clinical application, these results are encouraging because increasing use is being made of intravenous injection of ALG into patients in order to avoid the painful local reactions which often occur with intramuscular or subcutaneous injection[10]. By taking appropriate precautions, including preliminary intradermal tests, slow injection and simultaneous administration of corticosteroids and antihistamines, the risk of acute anaphylaxis can be greatly reduced. Whether or not the risk of subsequent renal insufficiency as a result of damage to glomerular basement membrane or deposition of antigen–antibody complexes will prove to be serious with intravenous administration remains to be seen. Survival experiments and electron microscopic studies will, it is hoped, provide an answer to this question.

Effect of Adjuvants on the Immunosuppressive Properties of Antilymphocytic Globulin

IN recent years we have been primarily concerned with investigating factors affecting the immunosuppressive properties of antilymphocytic antibody. Detailed studies on humoral systems in rats have indicated that effective immunosuppression is dependent on the intactness of the antilymphocytic IgG molecule, the time of its administration in relation to the antigen, the strain of rats used and the antigen under test[1]. Because adjuvants are generally known to influence markedly the ontogeny of the humoral immune response, it seemed desirable to ascertain whether the ability of antilymphocytic antibody to suppress the humoral response (in this case, to bovine serum albumin) was also dependent on the adjuvant in which it was administered. These preliminary studies demonstrate that such a dependence exists.

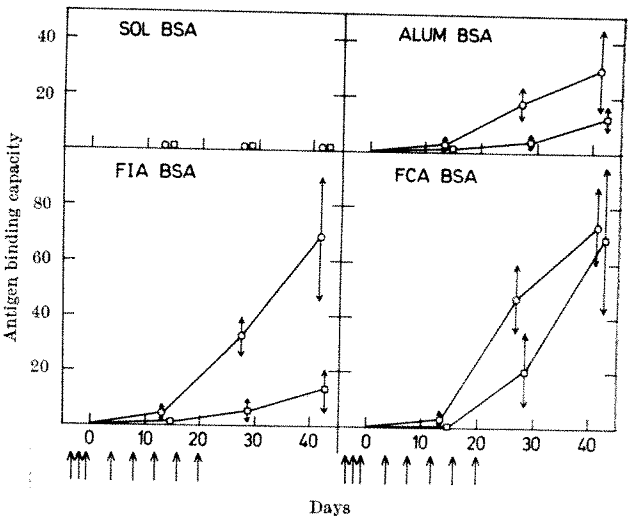

Fig. 1. The effect of antilymphocytic IgG on the response of hooded rats to bovine serum albumin. Note that in animals receiving the antigen in alum or Freund's incomplete adjuvant (FIA) there was a marked suppression of the humoral response throughout the experimental period. By contrast, animals receiving antigen in Freund's complete adjuvant (FCA) had fully recovered by day 42. ○, Normal IgG treatment; □, antilymphocytic IgG treatment.

The antilymphocytic serum was produced in horses using thoracic duct lymphocytes obtained from random bred Wistar rats. The immunization schedule and the preparation and properties of the normal horse and horse anti-rat lymphocyte IgG have been described in the preceding article[3]. The immunosuppressive studies were performed in groups (containing ten animals) of inbred hooded strain rats (sex female, age 5 months). The animals received intraperitoneal injections of 1 ml. of 2 per cent normal horse or antilymphocytic IgG on the days indicated in Fig. 1. On day 0 the rats were injected subcutaneously with 5 mg of bovine serum albumin (3X crystallized, Armour Pharmaceutical Co.). This was administered in soluble form (non-centrifuged in phosphate buffered saline) or as a suspension in 6·25 mg of alum ('Alhydrogel' supplied by the Supefos Export Co., Copenhagen) or in 1 ml. of Freund's complete or incomplete adjuvant (supplied by Difco, Detroit, Michigan).

The animals were bled by cardiac puncture on days 0, 14, 28 and 42. The antibody content of the sera obtained was assessed by the ammonium sulphate procedure of Farr[4], the results being expressed as antigen binding capacities (μg of BSA nitrogen bound by 1 ml. of rat serum). These values were estimated in a system containing 0·2 μg of bovine serum albumin nitrogen per test, the end point being the dilution of serum which bound 33 per cent of the test antigen. Standard antiserum and normal controls were used throughout these tests. Further details of the Farr and labelling procedures used are recorded elsewhere[2,4-6].

The mean antigen binding capacities observed are plotted together with their standard deviations (Fig. 1). A significant immune response was detected only in those animals receiving the test antigen incorporated in adjuvants. Furthermore, it will be noted that throughout the 6 weeks of the experiment the antilymphocytic IgG caused a significant suppression of the humoral response of animals injected with antigen incorporated in alum or Freund's incomplete adjuvant. By contrast, in the Freund's complete adjuvant group, the animals treated with antilymphocytic globulin quickly recovered their immunocompetence, the antigen binding capacities observed on day 42 being similar to those observed in animals treated with normal IgG. Thus the ability of antilymphocytic IgG to suppress the primary humoral response to bovine serum albumin is dependent on the adjuvant in which it is incorporated.

There are possible, though as yet untested, explanations of the above observations. Previous radioimmunoelectrophoretic studies on the immune response of rats to a variety of antigens, including bovine serum in Freund's complete adjuvant and bentonite, have clearly demonstrated the presence of five classes or sub-classes of antibody in this species, and shown that the relative distribution of antibody activity varies throughout the post-immunization period[7,8]. Furthermore, detailed investigations in mice have indicated that the quantity and quality (or class) of antibody evoked in response to antigens are dependent on the adjuvant in which it is incorporated[9,10]. On the basis of these observations it is claimed that adjuvants can markedly affect the expression of H chain genes[9], presumably by influencing the recruitment proliferation and/or maturation of specific antibody producing cells[10]. In the present studies, similar cytokinetic changes may have been occasioned by the mycobacterium component of the Freund's complete adjuvant. Thus an accelerated recovery of the antilymphocytic globulin treated cells or the selective proliferation of a population of antilymphocytic globulin refractive cells which produces antibody may have accompanied administration of this material. Such a population of cells might be responsible for the production of a select class or sub-class of antibody, and experiments are currently under way to test this hypothesis.

We thank Dr N. F. Anderson and Dr R. Dalton for producing the antilymphocytic serum, Mr C. Shepley for preparing the figure, and Professor M. F. A. Woodruff for his encouragement.

Adding a Ventricle instead of transplanting a Heart

IN heart transplant operations, as practised at present, an unpaired vital organ is excised and another of doubtful viability and doubtful compatibility is substituted. It is no surprise to find that these operations are looked on with some disfavour and have a high mortality rate and poor long term results.

Most patients considered for heart transplants suffer from coronary artery disease and their disability is the consequence of impairment of contraction of the left ventricle. An operation which mounted a donor left ventricle parallel to their own, sharing the work load between the two hearts, might be all they need.

I have shown the feasibility of such an operation experimentally. The donor heart is placed upside down next to the recipient heart with the two left atria adjacent. The atrial appendage and adjacent atrial walls are excised and the two atria joined together to form a common chamber. The donor aorta is anastomosed end-to-side to the descending thoracic aorta. Coronary sinus blood is returned to the circulation by making an atrial septal defect in the donor heart. The donor right ventricle is defunctioned by making the tricuspid valve incompetent. All vessels in the donor heart except the aorta are tied off.

I have implanted additional hearts in this way into seven dogs, and had six immediate survivors. Three died after 9, 9 and 6 days with rupture of the anastomoses from infection. In one the donor heart went into cardiac arrest even before being excised, and showed no signs of activity after the second day. At present one dog is alive after 9 days and another after 48 days. The latter is showing signs of rejection for the first time. Except in one case, the ventricles have been seen to eject blood against the blood pressure created by the recipient heart. The exception was in the donor heart which was in poor condition when implanted. On some occasions the blood pressure produced by the donor has been equal to that of the recipient heart. When the recipient heart is healthy, however, it is not possible to see the ejection from the donor heart on the blood pressure trace. The obvious next step is to impair the function of the recipient left ventricle and to see the extent to which the donor left ventricle is able to take over the load.

The arrangement has interesting experimental possibilities. Its great advantage is that rejection does not impair the blood supply to the transplanted heart; rejection can be studied without the accompanying cardiac failure and ischaemia which must occur if a single transplanted heart rejects. The reaction of a denervated heart to drugs can be compared with that of the normal heart.

It may be possible to consider this operation eventually for human transplants, for it has several theoretical advantages. First, the recipient's heart is not excised; second, the operation can be done without a heart–lung machine; third, rejection does not totally jeopardize the patient; and fourth, the donor heart, if rejected, could be excised and another substituted.

Some Properties of Angiotensin Converting Enzyme in the Lung *in vivo*

THE lung has many important metabolic functions[1,2] which include the selective activation or inactivation of endogenous peptides. Bradykinin is inactivated on transit through the pulmonary circulation[3,4], probably by at least two endopeptidases[5], but other peptides such as angiotensin II (refs. 6–10), polistes kinin[11] and eledoisin[3,4] pass through without loss.

The lungs also contain a highly active angiotensin converting enzyme[8,12–15]. This enzyme removes histidine and leucine from the C-terminal of angiotensin I, thereby generating angiotensin II, which is 10–50 times more potent physiologically. Converting enzyme was first isolated from plasma[16,17], but the activity of the plasma enzyme is too low to account for the rapid conversion of angiotensin I to II *in vivo*[12,13].

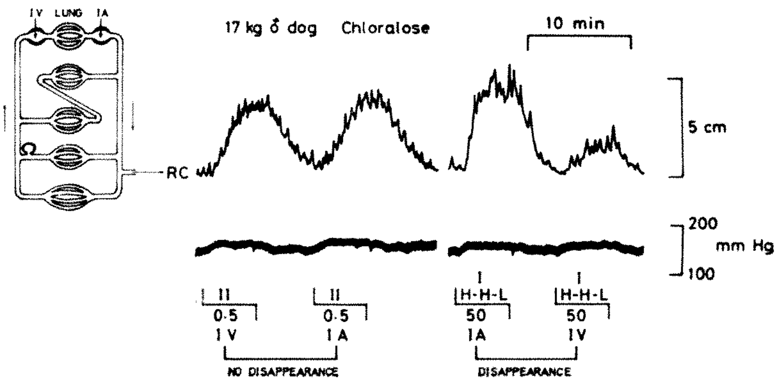

Fig. 1. Male dog (17 kg). The diagram illustrates the route of infusions: intravenous (IV) infusions were given into the femoral vein, intra-aortic (IA) infusions were given into the root of the aorta and blood at 10 ml./min was sampled continuously from the femoral artery for superfusion of the rat colon (RC). Intravenous and intra-arterial angiotensin II (0·5 μg/min) produced the same effects on the rat colon. HHL analogue (50 μg/min) intravenously gave a contraction very much smaller than that produced by 50 μg/min intra-arterially, showing inactivation in the pulmonary circulation. Time, 10 min; vertical scales, 5 cm and mm Hg.

The converting enzyme in lung may be an endopeptidase similar to that in plasma, or a carboxypeptidase which first cleaves the leucine and then the histidine from angiotensin I. The availability of an undecapeptide related to angiotensin but containing an extra histidine residue at position 10 ([Ile^5, His^9, His^{10}, Leu^{11}]-angiotensin II; HHL analogue) led us to test this substance for its ability to act at angiotensin receptors and also as a substrate for converting enzyme. The angiotensin-like activity of the HHL analogue was measured on rat colons[18], superfused[19] either with Krebs solution or with blood, using the blood-bathed organ technique[20], as previously described[12,13].

When superfused with Krebs solution, the rat colon preparations were contracted by infusions of angiotensin II (Hypertensin, Ciba) to give concentrations of 1–10 ng/ml. High concentrations (200–2,000 ng/ml.) of the HHL analogue were necessary to produce similar contractions (Table 1). Thus the HHL analogue had 0·5–0·6 per cent of the activity of angiotensin II in Krebs solution. In arterial blood of dog or cat (contact time 30 s), the relative activity was 1·0–1·2 per cent. After intravenous infusions, however, the relative activity on both blood pressure and the rat colon preparations was 0·2–0·3 per cent. Because the assay organs were bathed in carotid arterial blood, the reduction in the relative activity of the HHL analogue after intravenous infusion suggested a disappearance or inactivation of the peptide during passage through the lungs. In direct comparison, intravenous infusions of the HHL analogue (20–100 μg/min) induced a smaller contraction of the rat colon than that produced by the same rate of infusion into the root of the aorta. A comparison of the contractions showed that 40–50 per cent (five observations) of the HHL analogue disappeared in transit through the lungs of either dog or cat.

Table 1. RELATIVE ACTIVITY OF [ILE^5]-ANGIOTENSIN I AND THE HHL ANALOGUE ON THE RAT COLON IN KREBS SOLUTION, AFTER INCUBATION IN BLOOD FOR 30 S AND AFTER INTRAVENOUS INFUSIONS

	Angiotensin I (from ref. 13)	HHL analogue (per cent)
Krebs solution	2–10% (10)	0·5–0·6 (4)
Blood (30 s)	3–30% (11)	1·0–1·2 (8)
Intravenous	20–60% (10)	0·2–0·3 (6)

Activity is expressed as the range of percentage activity of angiotensin II amide.

The figures in parentheses refer to the number of observations made on the assay organs.

Fig. 1 illustrates this disappearance. Infusions of angiotensin II (0·5 μg/min) gave similar contractions of the blood-bathed rat colon when given either into the aorta or intravenously, showing that angiotensin II passed through the lungs without loss. An intravenous infusion of the HHL analogue (50 μg/min), however, was less potent than the intra-aortic infusion, showing that the HHL analogue was inactivated.

This inactivation of the HHL analogue is consistent with the converting enzyme of lung being an endopeptidase similar to that of plasma, for stepwise cleavage by a carboxypeptidase would have resulted in production of angiotensin II which is resistant to further breakdown by the lungs. This inactivation of the HHL analogue was unlikely to be caused by the action of an endopeptidase acting at any peptide links in the angiotensin II moiety of HHL because angiotensin II survives passage through the lungs. Possibly converting enzyme splits the His^9–His^{10} bond leaving [His^9]-angiotensin II, the activity of which could be very low.

Ferreira[21] has isolated from the venom of the South American snake *Bothrops jararaca* a mixture of peptides ("bradykinin potentiating factor", BPF) which inhibits kininases[3,22,23]. BPF also inhibits converting enzyme both in cell-free extracts of dog lung[24] and in isolated perfused lung[8]. We have now tested BPF as a converting enzyme inhibitor *in vivo*. Because of the scarcity of the extract this has been done in rats.

Six rats of either sex (250–300 g) were anaesthetized with 6 mg/100 g of pentobarbitone sodium intraperitoneally and given 4 mg/100 g of pentolinium tartrate subcutaneously. Cannulae were inserted into both external jugular veins and blood pressure was recorded from either the carotid or femoral artery. Intra-aortic injections were given through a fine polyethylene tubing inserted via the left carotid artery and advanced so that its tip lay above the aortic valves. Heparin (500 IU/100 g) was given intravenously and the mean blood pressure was recorded by a Statham *P23Db* transducer on a Beckman-Offner dynograph.

[Ile^5]-angiotensin I (10–100 ng) injected into the vein was twice as potent in raising the systemic blood pressure as when it was injected into the root of the aorta, confirming activation of intravenous angiotensin I in the lungs. Peripheral vascular beds inactivate about half of the angiotensin II reaching them[7–9], leaving the other half to recirculate. Thus even with 100 per cent conversion of angiotensin I to II in one transit through the lungs, the maximum possible difference between potencies of intravenous and intra-aortic injections would be two-fold.

The effect of BPF on the conversion of angiotensin I to II was examined in four other rats. An experiment is illustrated in Fig. 2. Panel *A* shows that 50 ng of angiotensin I produced a rise in blood pressure slightly greater than that produced by 20 ng of angiotensin II (a ratio of about 2 : 1). Panel *B* shows that during infusion of BPF (0·1 mg/min intravenously), although the pressor response to angiotensin II was unaffected, the response induced by angiotensin I was considerably reduced so that the ratio became about 15 : 1. Panel *C*, at a faster paper speed, also shows that the residual effect of angiotensin I in the presence of BPF is more prolonged than that of angiotensin II. Similar results were obtained in three more experiments. The inhibitory effect of BPF on the pressor activity of angiotensin I was rapidly reversible; within 5–10 min of stopping the infusion of BPF the pressor activity of angiotensin I had almost fully recovered.

These experiments show that BPF greatly reduces the hypertensive activity of angiotensin I *in vivo*. In view of the *in vitro* results with the same extract[8,24], it is reasonable to conclude that the reduction in activity is due to inhibition of lung converting enzyme. Experiments are in progress to determine whether the plasma converting enzyme is also inhibited by BPF.

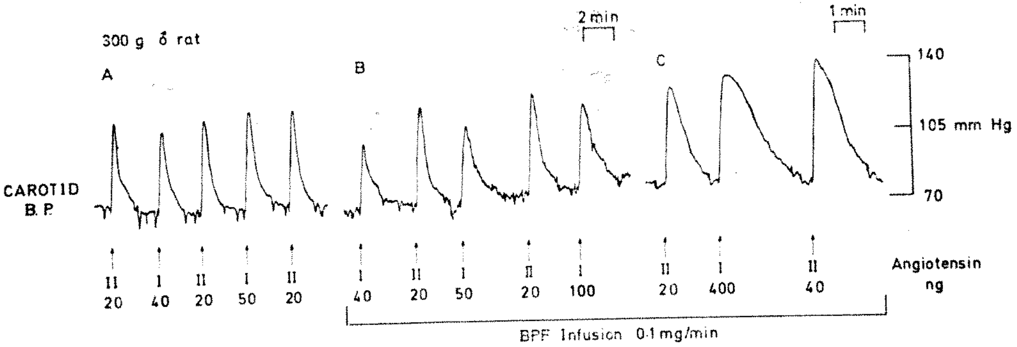

Fig. 2. Effects of BPF on the pressor responses to intravenous injections of angiotensin I and II in an anaesthetized rat (300 g). Panel *A* shows that angiotensin I was nearly half as potent as angiotensin II. The potency was reduced to about one-fifteenth of angiotensin II during BPF infusion (panels *B* and *C*). Time, 2 min in panel *A* and panel *B*; 1 min in panel *C*; vertical scales, mm Hg.

We thank Dr S. Wilkinson of the Wellcome Foundation for gifts of angiotensin I and the HHL analogue and Dr S. H. Ferreira for the gift of BPF. One of us (K. K. F. N.) was an overseas scholar of the University of Singapore. This work was supported by the MRC and the Wellcome Trust.

Effects on Smooth Muscle Preparations of Unidentified Vasoactive Peptides from Intestine and Lung

EXTRACTS of lung[1,2] and of small intestine[3] from the pig contain previously unidentified vasoactive peptides which, when given intravenously, increase peripheral blood flow and cause a systemic hypotension, both effects being long lasting. Although the peptide fractions from the lung and small intestine are extractable by similar techniques, the vascular responses they elicit are somewhat different. One peptide from the intestine induced a quicker and more pronounced vasodilatation than either the second peptide from intestine or that from lung[3]. These substances have not yet been completely purified, and so their activity may be due to a single compound or to several different ones. Because of the short supply of extracted peptides, investigation of their biological activity has been limited largely to their peripheral vasodilator effect.

Superfusion[4] of several isolated organs in cascade[5,6] was used to clarify some of these points. We tested the activity of three peptide fractions, one from the lung and two from the gut, on a variety of isolated smooth muscle preparations to determine: (1) whether a particular tissue was suitable for detecting and assaying the peptides; (2) the activity of the peptides on different smooth muscle preparations; (3) the degree of similarity between the activity of the three peptide fractions; and (4) any resemblance between the actions of the peptides and those of known compounds. The activity of the following peptide preparations was investigated: (L) a desalted methanol extract from hog lung[1,2], (G 1) the peptide fraction of methanol extract of hog small intestine which, on chromatography on carboxymethyl cellulose (CMC),

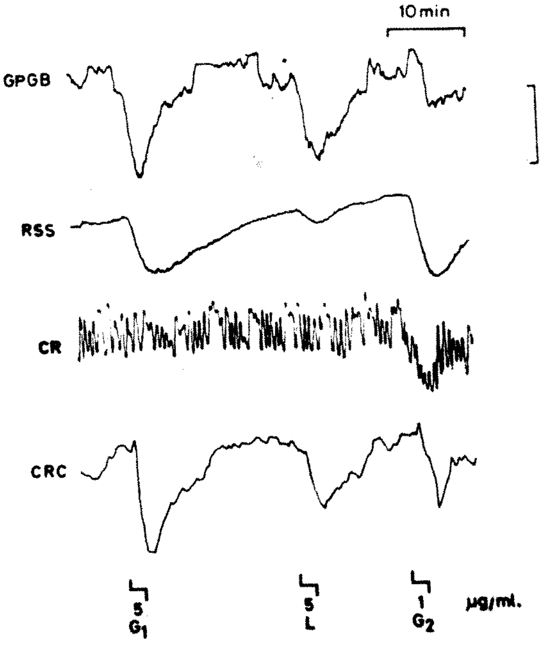

Fig. 1. A guinea-pig gall-bladder (GPGB), rat stomach strip (RSS), chick rectum (CR) and chick rectal caecum (CRC) were superfused with Krebs solution at 10 ml./min. Each of the three peptides G 1 (5 μg/ml.), L (5 μg/ml.) and G 2 (1 μg/ml.) relaxed these tissues, but the pattern of activity was different. Time 10 min, vertical scale 5 cm.

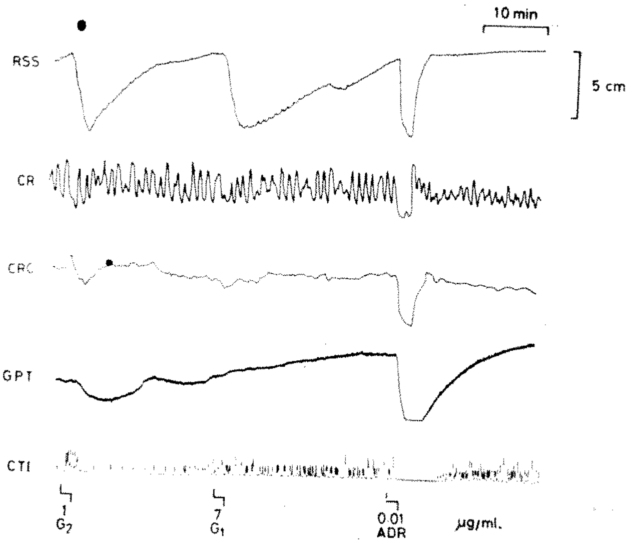

Fig. 2. A rat stomach strip (RSS), chick rectum (CR), chick rectal caecum (CRC), guinea-pig trachea (GPT) and cat terminal ileum (CTI) were superfused with Krebs solution at 10 ml./min. G 2 (1 µg/ml.) relaxed all tissues except the cat terminal ileum which contracted. G 1 (7 µg/ml.) was much less potent. The relative activities of G 1 and G 2 in the tissues were different from that of adrenaline (0·01 µg/ml.). Time 10 min, vertical scale 5 cm.

in phosphate buffer at pH 8, was eluted ahead of secretin[7] (pre-secretin gut fraction), and (G 2) the peptide fraction of the same extract which remained absorbed to the CMC column in the same conditions and was eluted with 0·2 M HCl (post-secretin gut fraction). Further purification of G 2 yielded another fraction labelled vaso-inhibitory peptide (VIP).

The lyophilized preparations to be tested were dissolved in physiological saline and, like the calibrating solutions, were added to the perfusing fluid by a constant flow infusion pump.

The isolated smooth muscle preparations were chosen from those in use in this laboratory. They were superfused at 10 ml./min with Krebs solution warmed to 37° C and bubbled with 5 per cent CO_2 in O_2. The tissues were arranged in two cascades, each containing two or three preparations[5,6]. The sensitivities of the preparations to histamine, adrenaline, and so on, were demonstrated and the three peptides were then tested. In the concentrations used (10^{-8}–2×10^{-6} g/ml.), the peptides had no action on nine of the fifteen preparations tested. These were the longitudinal muscles of the guinea-pig ileum, cat jejunum[8], rat colon[9], rat duodenum[10] and rat uterus; rat atria, spirally cut strips of rabbit aorta[11], longitudinal strips of rabbit portal vein[12] and duck pulmonary artery[13].

The peptides (10^{-7} g/ml.) were active on six tissues (Figs. 1 and 2), the rat stomach strip[14], chick rectum[15], chick rectal caecum[16], guinea-pig trachea (cut as a zig-zag) and longitudinal strips of guinea-pig gall-bladder and cat terminal ileum. The spectrum of activity distinguished them from the known substances tested, including bradykinin, angiotensins, secretin, prostaglandins, 5-hydroxytryptamine and the catecholamines. The most potent preparation was the post-secretin gut fraction (G 2) or VIP and the least potent was the pulmonary fraction (L). The impurity of the fractions may, however, have contributed to the variation in potency between them. All these preparations were relaxed by fraction G 2 except the cat terminal ileum which was contracted. This contraction was selectively abolished by 10^{-7} g/ml. of mepyramine, so it was probably due to slight contamination with histamine. This conclusion was further reinforced by use of the more purified fraction of G 2. VIP had about four times the relaxant potency of G 2 on the rat stomach strip and guinea-pig trachea, but none of the contractor activity on the cat terminal ileum (Fig. 3).

The other gut peptide (G 1) and the lung peptide (L) did not contract the cat terminal ileum, but they relaxed guinea-pig gall-bladder, rat stomach strip, chick rectum and rectal caecum. They had little or no action on the guinea-pig trachea. Thus even though the inhibitory reactions to the three peptide preparations were similar, they could be distinguished by their relative reactions on the different smooth muscle preparations. Doses of peptide fractions G 1 and G 2 (or VIP) inducing comparable relaxation of the rat stomach caused unequal relaxation of the chick rectum or of the chick rectal caecum (Figs. 1 and 2). Also, while giving an equivalent relaxation of the guinea-pig gall-bladder to that caused by G 1, a dose of L produced a much weaker relaxation of the rat stomach (Fig. 1). These differences suggest that the

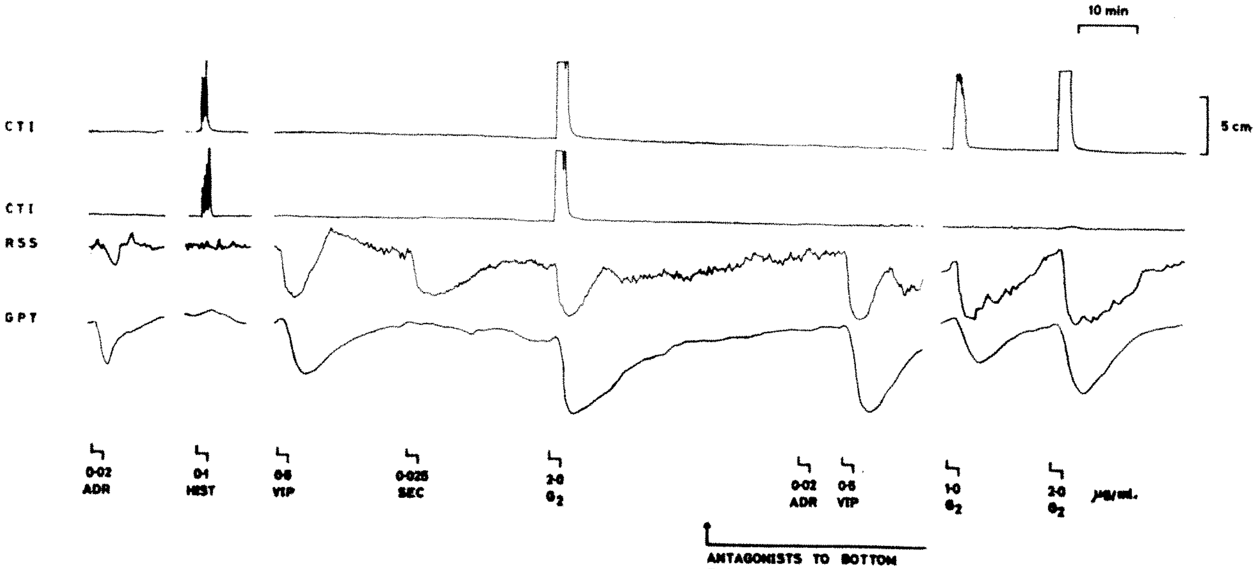

Fig. 3. Two cat terminal ileums (CTI), a rat stomach strip (RSS) and a guinea-pig trachea (GPT) were superfused with Krebs solution at 10 ml./min. The first two panels show that adrenaline (0·02 µg/ml.) relaxed the RSS and GPT whereas histamine (0·1 µg/ml.) contracted the CTI and GPT. VIP (0·5 µg/ml.) had about the same potency as G 2 (2 µg/ml.) on the RSS and GPT, but did not contract the CTI. Secretin (0·025 µg/ml.) relaxed only the RSS. The mixture of antagonists (for details, see text) was applied to the lower three tissues. It abolished the relaxant actions of adrenaline but did not affect the relaxant actions of VIP or G 2. The contraction of the CTI in response to G 2 was abolished. Time 10 min, vertical scale 5 cm.

active principles in the pulmonary and intestinal extracts are not identical.

The reactions of the isolated tissues distinguish the main activity of all of the peptide fractions tested from histamine (which contracts chick rectum, cat ileum and guinea-pig gall-bladder), bradykinin (which contracts rat uterus, rat stomach strip, cat jejunum and cat ileum), prostaglandins (which contract chick rectum, rat colon and rat stomach strip), and catecholamines (which stimulate atrial muscle, contract rabbit aorta, rabbit portal vein and duck pulmonary artery and relax rat colon, rat stomach and chick rectum). The effects of various antagonists further distinguished these peptides from known substances. In concentrations which blocked the effects of catecholamines, phenoxybenzamine (10^{-7} g/ml.) and propranolol (2×10^{-6} g/ml.) did not antagonize the effects of the peptides. When a combination of several antagonists was used (Fig. 3) the effects of G 2 and VIP were unaltered, except for the abolition of the response of the cat terminal ileum due to contamination of G 2 by histamine. The mixture of antagonists contained mepyramine maleate (10^{-7} g/ml.) to block the effects of histamine, methysergide bimaleate (2×10^{-7} g/ml.) to antagonize 5-hydroxytryptamine, hyoscine hydrobromide (10^{-7} g/ml.) to antagonize acetylcholine, phenoxybenzamine hydrochloride (10^{-7} g/ml.) and propranolol hydrochloride (2×10^{-6} g/ml.) to antagonize the α and β-effects of catecholamines.

Fig. 3 also shows that synthetic secretin differed from the G 2 and VIP extracts, for it relaxed only the rat stomach strip. The relaxation of the rat stomach strip by secretin was dose-dependent and occurred at low concentrations (10–100 ng/ml.). This unexpected effect may be useful as a bioassay for preparations of secretin. It also suggests that the inhibitory activity of secretin on intestinal muscle should be further investigated.

The demonstration that the three unidentified peptides have potent inhibitory effects on tracheal muscle and on several different intestinal smooth muscles, as well as vasodilator activity[1-3], makes it possible that the peptides have a physiological function. This might be either as a local hormone, affecting the smooth muscle of the organs containing them, or as a circulating hormone. Their inhibitory actions on vascular, respiratory and intestinal smooth muscle would certainly be prolonged if they were released into the blood stream.

One important feature of these results is their possible application for the assay of the active peptides during further purification. For instance, in the case of G 2 (or VIP), use of the rat stomach should provide an assay method which is many times more sensitive and also more specific than the method used so far, namely, intra-arterial injection in the dog hind limb. In further work, use of the blood-bathed organ technique[17] should afford opportunities for studying aspects of the metabolism and possible release of these newly identified agents *in vivo*.

We thank Dr M. Ondetti of the Squibb Institute for Medical Research for a sample of synthetic secretin and the Wellcome Trust, the Medical Research Council, the US Public Health Service, the American Heart and the National Tuberculosis and Respiratory Disease Associations for grants. S. I. S. is a recipient of a research career development award from NIH.

Magnetic Fields and the Number of Blood Platelets

INVESTIGATIONS of mice exposed to strong homogeneous magnetic fields have revealed that the number of megakaryocytes decreases in the bone marrow and increases in the spleen of the exposed animals[1]. It is currently assumed that platelets originate in the bone marrow when the cytoplasm of megakaryocytes becomes fragmented; the platelets then enter the blood stream. In mice the mean circulating life-span of platelets is approximately 4 days[2]. The purpose of the investigation we report here was to find out whether magnetic fields, of the same strength as those in which we have observed the change in the number of megakaryocytes in the bone marrow, would also alter the number of platelets in the circulating blood.

Female virgin DBA/J2 strain mice, 100–120 days old, were used in two experiments. Six mice in the first experiment, and five in the second, were placed for 20 days in a 9,000 oersted homogeneous, vertical magnetic field, while an equal number of mice were kept in identical "dummy magnets". Details of the magnet, the cage arrangement and so on can be found in ref. 1.

Blood was taken every 3–6 days (always at the same time of the day) from the tail vein of the mouse. From a sharp incision made with a razor blade, blood was removed with the help of a 13 μl. volume capillary syringe ('Unopette') and was immediately mixed with 1·3 cm^3 of 1 per cent ammonium oxalate, buffered to *p*H 6·5–6·8. After haemolysis of the red cells, the chamber of a haemocytometer was filled with the diluted blood sample and, when settling was completed, the number of blood platelets was counted with a phase contrast microscope (× 600, dark contrast objective). From each blood sample 200–400 platelets were counted. The standard error of the mean of a group of five or six mice was on average 4 per cent. Occasionally deviations from the average in a single animal amounted to 25 per cent.

Fig. 1 shows the relative change in the number of platelets: the average of the two magnet group values expressed as a percentage of the corresponding control group values. The mice kept in the magnetic field showed, in both experiments, as early as the third day of their exposure to the field, a 25 ± 3 per cent increase in the number of platelets over the value of their controls. From the tenth to the last day of their residence in the field, the difference between the magnet and control groups vanished. The observed variation in the number of platelets could be interpreted as a reaction of the organism to the stress of the magnetic field[3]. After removal of the mice from the magnetic field we see a repetition of the same pattern: an increase in platelet number. Further investigations will have to clarify whether the magnetic field merely changes the number of

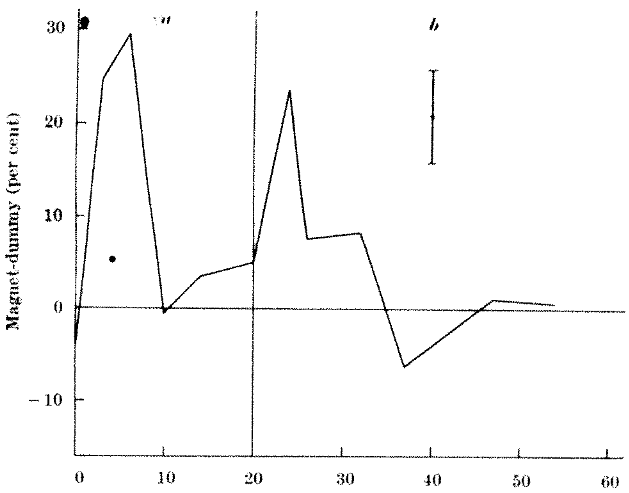

Fig. 1. Average platelet number of mice expressed as percentage of the control group values, during exposure to a magnetic field of 9,000 oersted (*a*) and after removal of the animals from the field (*b*). The bar shows the average standard error of one point.

blood platelets, or whether it also produces morphological alterations in them. Investigations in a magnetic field may contribute to the further elucidation of the clotting mechanism, and we may speculate that ultimately magnetic fields may be used to control some haemorrhagic disorders.

We cannot rule out the possibility that the beneficial effect we obtained by counteracting radiation syndromes[4], through pre-irradiation exposure of mice to magnetic fields, may have been caused partly by the increased number of platelets in the circulating blood after the magnetic exposure ended. The increased number of platelets may have reduced the death rate from intestinal haemorrhages.

Simultaneous Measurement of Cytochrome a_3 Reduction and Chemoreceptor Afferent Activity in the Carotid Body

The discharge frequency of carotid body chemoreceptors increases progressively as p_aO_2 is reduced below 250–150 mm Hg[1]. Chemical agents which either inhibit electron transport or uncouple oxidative phosphorylation in other tissues also increase chemoreceptor discharge[2,3]; however, the fall in pO_2 required to stimulate the receptors physiologically is much smaller than that required to influence mitochondrial respiration in other tissues[4,5]. It appears then that mitochondria of the carotid chemoreceptors must have unusual properties if they play a part in the oxygen related generation of chemoreceptor impulses. To evaluate the relationship between chemoreceptor discharge and respiratory chain activity we simultaneously measured the frequency of the potentials and the cytochrome a_3 reduction level in the carotid body. The organ was perfused with physiological saline *in vitro* because it must be both adequately oxygenated and free of haemoglobin to permit spectrophotometric measurement of cytochrome a_3 reduction.

Cats were anaesthetized with sodium pentobarbitone and the carotid bifurcation and sinus nerve exposed. The preparation was heparinized, and all arteries branching from the bifurcation were ligated. After stopping the heart with a large dose of anaesthetic, the carotid bifurcation was flushed free of blood with Locke's solution[6] injected into the common carotid artery. The bifurcation with the attached sinus nerve was removed and placed in oxygenated Locke's solution. All tissues surrounding the carotid body were removed to facilitate transmission of light and the adventitia stripped from the sinus wall to minimize baroreceptor afferent activity in the sinus nerve[7]. The preparation was transferred to a chamber—like that used to superfuse the carotid body[6,8]—which was provided with a second inlet tube with which the common carotid artery was cannulated so that the carotid body could be both perfused and superfused. Reservoirs containing Locke's solution plus dextran equilibrated with oxygen (100, 20, 12·8 and 5 per cent) and nitrogen (100 per cent) were placed above the chamber to provide a perfusion pressure of 130 mm Hg. Flow in the superfusion line was controlled with a clamp so that the level of solution in the chamber was just sufficient to cover the carotid body. The temperature of the bathing solution in the chamber was maintained at 36° C. Liquid paraffin was layered over the solution and the sinus nerve lifted into the paraffin and placed on a platinum electrode. Action potentials were amplified and displayed on an oscilloscope and also introduced into a pulse height selector. Pulses of constant amplitude and duration then triggered a rate meter, the output of which was recorded on a Grass polygraph.

The preparation was observed with a microscope equipped with a × 11 objective lens. A photomultiplier tube was introduced into the body tube of the microscope so that the end-window intercepted the light beam at a plane where a distinct image of the object was not formed. Transillumination was provided by rapidly alternating beams of light from two monochromators using the same incandescent lamp as a light source. The wavelength span of one beam (the measuring beam) was chosen to coincide with the absorption peak of a cytochrome or of haemoglobin; the other provided a reference signal. The latter was kept constant by feedback on the voltage to the dynode stages of the photomultiplier. Changes in light transmission were measured differentially between the two beams. This ensures elimination of artefactual amplification or attenuation of existing differences between the two light signals caused by large equal changes (for example, by light scattering) in the light beams during passage through the tissue. This technique is an adaptation and extension of dual-wavelength spectrophotometry introduced by Dr B. Chance.

Oxygen response curves were plotted from the ratemeter recordings of chemoreceptor discharge in four experiments. Discharge was maximum when the carotid body was perfused with solution equilibrated with N_2, and it was 11–20 per cent of maximum during perfusion with air equilibrated solution. The oxygen response curves of the carotid body perfused *in vitro* are similar to curves derived from comparable whole sinus nerve recordings in intact anaesthetized cats[9]. Slight differences in shape and position of the response curves may result from a lack of

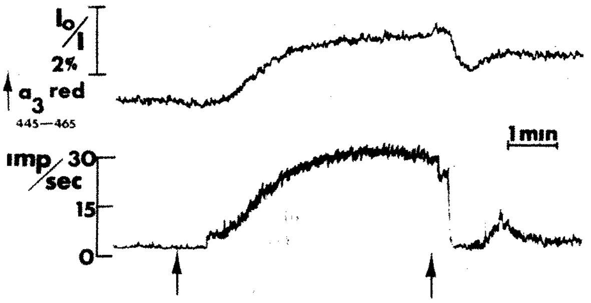

Fig. 1. Simultaneous measurement of cytochrome a_3 reduction and chemoreceptor activity in the carotid body. Upper: cytochrome a_3 reduction state measured at 445 nm–465 nm; calibration shows 2 per cent transmission. Lower: ratemeter recording of chemoreceptor afferent activity (impulses per s); time constant 2·0 s. At first arrow, perfusate equilibrated with 100 per cent O_2 replaced by perfusate equilibrated with 100 per cent N_2. At second arrow, N_2 perfusate replaced by solution equilibrated with 5 per cent O_2. Switching solutions produced an artefactual deflexion which precedes the onset of the maintained decline in both traces.

CO_2 in the perfusate and from the absence of a factor in blood other than haemoglobin which may influence receptor activity[3,10].

The reduction state of cytochrome a_3 was monitored on the basis of absorbance at 445 nm (measuring beam) minus that at 465 nm (reference beam). When perfusate equilibrated with 100 per cent O_2 was replaced by one equilibrated with 100 per cent N_2, there was an increase in $A_{445\ \mathrm{nm}}$ compared with $A_{465\ \mathrm{nm}}$ after a variable delay (Fig. 1, upper trace). We established that a compound with a maximum absorption at 445 nm is present in the carotid body by monitoring the optical signal at wavelengths between 410 nm and 465 nm while switching between 100 per cent O_2 and 100 per cent N_2 perfusates. The optical change does signal an increase in the level of reduction of cytochrome a_3. The records show typically an S-shaped curve for this reaction. When haemoglobin is present its deoxygenation can be measured in terms of $A_{437\ \mathrm{nm}}-A_{465\ \mathrm{nm}}$. On switching to solution equilibrated with N_2 the onset of the signal is much more sudden and its initial rate of rise is the maximal one. Thus the kinetics more closely resemble those of a first order reaction, and the half-maximum value is attained much earlier than with cytochrome a_3.

Surprisingly, there was a small (10–12 per cent) but reproducible increase in cytochrome a_3 reduction level when solution equilibrated with air was substituted for one equilibrated with 100 per cent O_2. The oxygen consumption of the saline perfused carotid body is about 1·5 ml./min/100 g (less than 20 per cent of that in the blood perfused organ[11]), and saline flow is often four to five times the blood flow of 40 µl./min[3]. For a carotid body weighing 2 mg the O_2 consumption is 3×10^{-5} ml./min. From the Fick relationship, an arteriovenous O_2 difference of 0·03 ml./100 ml. can be calculated at a saline flow of 100 µl./min. Thus the decrease in pO_2 along the carotid body capillaries is only 10 mm Hg. Because the pO_2 drop from capillaries to chemoreceptors is estimated to be approximately 10 mm Hg (ref. 5), the receptors must be exposed to a pO_2 only 20 mm Hg below the measured pO_2 of 142 mm Hg in the air equilibrated solution. The observation that the cytochrome a_3 reduction level is increased at approximately 120 mm Hg is not compatible with the current view that a high affinity of cytochrome a_3 for oxygen keeps a_3 in the oxidized state at pO_2 levels above about 5 mm Hg (see ref. 1).

The lower trace of Fig. 1 illustrates the change in chemoreceptor impulse frequency when a perfusate equilibrated with 100 per cent O_2 is replaced by one equilibrated with 100 per cent N_2. The simultaneous measurements of reduction level of cytochrome a_3 and chemoreceptor impulse frequency reveal that the onset of cytochrome a_3 reduction precedes slightly or is simultaneous with the rise in impulse frequency. Analysis of the continuous process demonstrated a close correlation between the time course of cytochrome a_3 reduction and increase in chemoreceptor impulse frequency (Fig. 2). In some experiments, however, impulse frequency increased more rapidly than cytochrome a_3 reduction level in the range between 12·8 and 5 per cent O_2.

Fig. 1 also shows the effect of changing from a nitrogen equilibrated solution to one equilibrated with 5 per cent O_2. At the first indication of increased cytochrome a_3 oxidation, there was a precipitous fall in impulse frequency followed by a rebound to an intermediate rate of discharge. We repeatedly observe this effect on switching from N_2 perfusate to solutions equilibrated at a higher pO_2. Fig. 2 (closed circles) correlates cytochrome a_3 reduction level and impulse frequency in the steady state during such stepwise increases in pO_2.

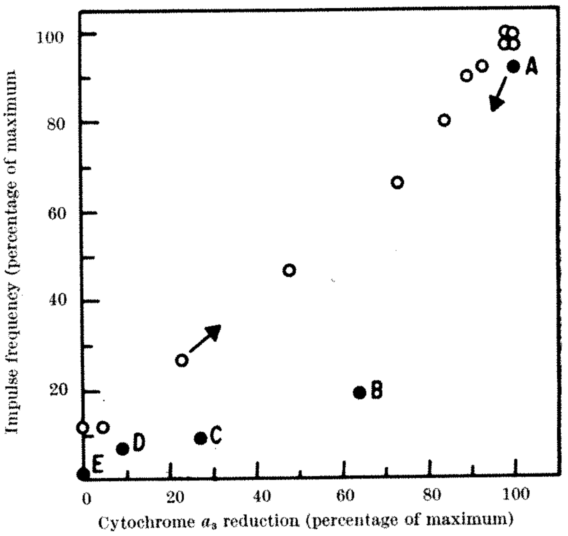

Fig. 2. Correlation between cytochrome a_3 reduction level and chemoreceptor activity during changes in pO_2 (graph derived from record shown in part in Fig. 1). ○, Continuous plot (20 s interval) of correlation on switching from 100 per cent O_2 to 100 per cent N_2. ●, Steady state plot during stepwise return to 100 per cent O_2. Point *A*, 100 per cent N_2; *B*, 5 per cent O_2; *C*, 12·8 per cent O_2; *D*, 20 per cent O_2; *E*, 100 per cent O_2. Maximum for cytochrome a_3 reduction and chemoreceptor impulse frequency is the value attained during perfusion with 100 per cent N_2 solution, and cytochrome a_3 is considered to be completely oxidized during perfusion with 100 per cent O_2 solution.

The short latency of the change in chemoreceptor firing rate with a change in cytochrome a_3 reduction level (especially towards increased oxidation) makes it extremely unlikely that impulse generation is mediated through the usual processes of intermediary metabolism, oxidative phosphorylation or ATP level as suggested by the results of experiments with metabolic inhibitors[2,3]. A more direct link with the reduction state of the members of the respiratory chain is indicated. In this regard the results are of some considerable interest because they also imply that the affinity of the cytochrome a_3 of the carotid body preparation is much lower than that revealed by studies on isolated, mammalian mitochondria.

Localization of Acetylcholinesterase by Immunofluorescence in Eel Electroplax

ACETYLCHOLINESTERASE (AChE), an important component of a variety of excitable membranes, seems to be associated with excitability[1]. Considering the possible role of AChE in the electrogenic action of cholinergic agonists, we prepared antibodies against AChE purified from the electric organ of *Electrophorus electricus*. This paper describes the cytological distribution of material reacting with a rabbit anti-AChE serum which, after absorption with eel serum, appears to be immunochemically homogeneous, in contrast to antisera recently obtained by others[2].

Purified AChE, a gift of W. Leuzinger and D. Nachmansohn (Columbia University), had been prepared following the method of Leuzinger and Baker[3]. The enzyme had a specific activity greater than 300 mmoles of acetylthiocholine/mg protein/h. A 1 mg solution, emulsified in Freund's complete adjuvant, was injected in a rabbit intramuscularly and intradermally; the injections were repeated a month later. Just before boosting, antibodies were already detectable. The antiserum was assayed with purified AChE (0·5 mg/ml. solution in 0·05 M phosphate buffer, *p*H 7·0) and with a commercially available AChE preparation (Sigma) 1·5 mg/ml. solution. (Specific activity: 80 mmoles of acetylthiocholine/mg protein/h.) Detection of antibodies directed toward AChE was made by the double diffusion technique of Ouchterlony. Only one precipitation band was found with purified AChE and it contained all the AChE activity detected with substrates for AChE, such as indoxylacetate or tetrazolium salts.

When commercial AChE was used, two bands of precipitation were seen, but only one of them showed an esterase activity. The enzymatically inactive band, which stained with amido black, seemed antigenically identical to a protein found in eel serum (Fig. 1). After absorption of anti-AChE rabbit serum with eel serum, this second band disappeared, leaving only the band bearing esterasic activity. This result was confirmed by immunoelectrophoresis[4]. With commercial AChE two bands were detected but only the more anionic band showed enzymatic activity.

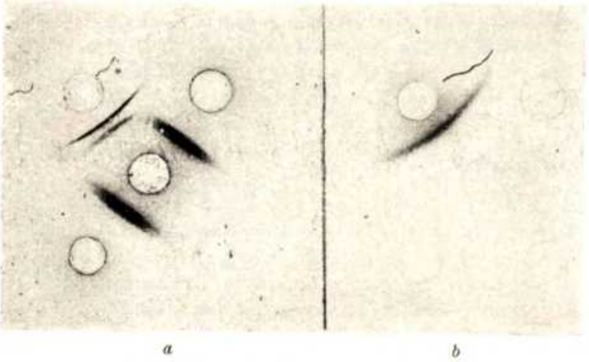

Fig. 1. Immunodiffusion (Ouchterlony) in 1·2 per cent ionagar gel and 0·025 M veronal buffer, *p*H 8·2. *a*, Protein stain (amido black); *b*, AChE stain (indoxylacetate). Centre well: antiserum to AChE. Upper left well: AChE sigma (1·5 mg/ml.). Upper right and bottom left well: eel serum.

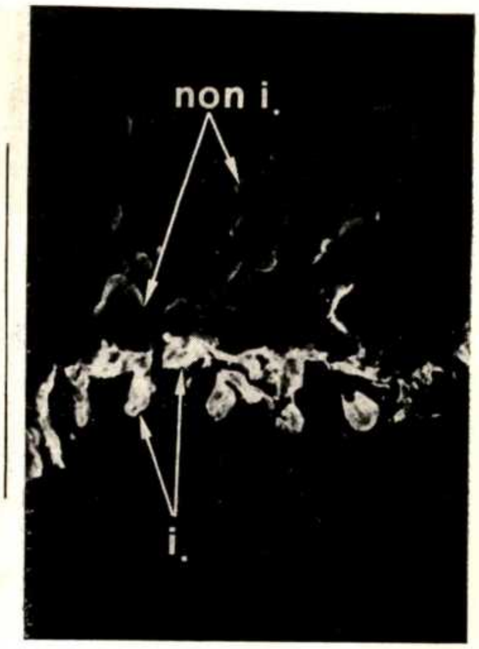

Fig. 2. Electroplax from the organ of Sachs, × 456. Frozen section, 16 μm in thickness. Indirect immunofluorescent method. Dilution of antiserum: 1/10. Leitz microscope with high pressure mercury lamp (exciter filter: BG 12, suppression filter: K 530). Bright field condenser. High speed Ektachrome film. Arrows *i* indicate the innervated side, arrows *non i* the non-innervated side. The vertical bar represents 100 μm.

In precipitation tests, after adding increasing amounts of immune serum to a constant dilution of AChE[5,6], residual enzymatic activity was measured following centrifugation[7]. It revealed that precipitation of AChE by the immune serum removed more than 85 per cent of the enzymatic activity of the AChE solution. In immunofluorescent studies, we used snap-frozen tissue because we observed thermal denaturation at 47° C, as demonstrated by a lateral shift in complement fixation curves, which indicates a conformational change[8]. Electroplaxes from Sachs's organ were cut along a plane parallel to the surface of the organ, in a cryostat at −20° C. Sections were exposed to a 1/10 dilution of immune serum (absorbed with eel serum) for 45 min and, after washing, to 1/10 or 1/20 dilution of fluorescein-conjugated anti-rabbit globulins, produced in goat (Hyland Laboratories). Alternate sections were stained by a modified thiocholine method for histochemical localization of AChE[9].

The innervated side appeared brightly fluorescent (Fig. 2), along the external infoldings of the membrane. This fluorescence contrasted with the appearance of the non-innervated side, although, on closer examination, parts of it exhibited a faint fluorescence. In comparison, the thiocholine method gave a distinct reaction, after a 2 min incubation, visible along the innervated side. After a 10 min incubation, a discrete reaction appeared on the non-innervated membrane, in agreement with the fluorescent data.

When these immunofluorescent results are compared with other histochemical studies made at the optical[10] or electron microscopical[11,12] level, it is clear that diffusion artefacts are less likely to take place with our use of immunochemical methods. Such a specific material demonstrated the presence of AChE not only in the innervated membrane, but also, at a much smaller degree, in the non-innervated side. Moreover, we recently observed fluorescing neural cells located in brain and cord of *Electrophorus*, after exposure to immune serum.

Effect of Drugs on Red Cell Fragility

MANY drugs which affect the nervous system seem to be capable of altering the physical properties of cell membranes[1]. The concept of membrane stabilizing drugs has evolved since Spirtes and Guth[2] observed an inhibition of mitochondrial swelling in the presence of chlorpromazine. Recently, a wide range of local anaesthetics and central nervous system depressants have been shown to stabilize the red cell membrane[3]. If concurrent membrane changes in nerve cells occurred and produced a decreased ionic permeability of axons or an inhibition of transmitter release, this would result in a depression of neuronal activity. It is unlikely, however, that drugs which act on membranes have a similar action on all cells, and in some cases specific organelles may be selectively involved. For example, Tanaka and Tizuka[4] showed that some anti-inflammatory drugs decrease the permeability of the lysosomal membrane to acid hydrolases. Also, even though barbiturates decrease the excitability of pre and postsynaptic neuronal membrane, with low concentrations of the drug, the predominant effect appears to be an inhibition of release of neurotransmitter[5].

We compare here the red cell membrane stabilization properties of several types of drugs, including those known to stimulate brain activity as well as some cerebral depressants. The barbiturates were used in this experiment because they show a wide range of effect: barbituric and thiobarbituric acids are pharmacologically inactive, but C5 alkyl substituted barbiturates produce sedation if the alkyl side chain contains less than 6–7 carbon atoms. Barbiturates with larger side chains may induce epileptic fits.

The effect of drugs on red cell fragility was measured by the method of Seeman and Weinstein[3], except that the buffered hypotonic saline solution was adjusted to *p*H 6·5. This was found to give a more sensitive indication of membrane stabilization than by using the recommended *p*H of 7·0. Each drug was examined in ten-fold dilutions between 10^{-3} and 10^{-8} M inclusive. In the presence and absence of drug the degree of haemolysis was measured by estimating the absorbance of the supernatant at 570 nm 15 min after suspending the washed red cell in 66·5 mM NaCl in 10 mM phosphate buffer at 21° C. The results were expressed as ratios of control/test absorbance values. When drugs were found to protect against osmotic haemolysis this ratio was less than 1. Table 1 lists optimum concentrations of the drugs which produce protection. As previously demonstrated by Seeman and Weinstein[3], chlorpromazine showed considerable stabilizing effects. Prenylamine also showed a comparable degree of red cell stabilization. This drug exhibits reserpine-like effects in its ability to deplete amine stores in neurones[6], and its ability to stabilize the erythrocyte membrane is also similar to reserpine[3]. None of the other drugs tested produced similar degrees of membrane stabilization. Further, there was very little correlation between pharmacological activity and the effect on red cell haemolysis. This was particularly evident with barbituric acid and thiobarbituric acid, which are pharmacologically inactive. The stabilization effect which these barbiturates produced was small and similar in degree to that produced by the hypnotic barbiturates—amylobarbitone, pentobarbitone and hexobarbitone—and also similar to the stabilization effects of the excitatory barbiturates 5-(2-ethyl hexyl)-5-ethylbarbituric acid and 5-(4-methyl heptyl)-5-ethylbarbituric acid. The thiobarbiturate thiopentone gave moderate protection against haemolysis, but no protection at all was detected with nealbarbitone, methyl phenobarbitone and secbutobarbitone.

Table 1

Drug	Concentration of drug which produced least haemolysis (M)	No. of observations	Haemolysis expressed as ratio control/test
Chlorpromazine	10^{-4}	9	0·17
Prenylamine	10^{-5}	9	0·29
Barbituric acid	10^{-7}	12	0·76
Amylbarbitone	10^{-6}	6	0·82
Pentobarbitone	10^{-6}	6	0·72
Hexobarbitone	10^{-6}	12	0·73
5-(2-Ethyl hexyl)-5-ethylbarbituric acid	10^{-6}	9	0·72
5-(4-Methyl heptyl)-5-ethylbarbituric acid	10^{-6}	6	0·84
Thiobarbituric acid	10^{-6}	9	0·88
Thiopentone	10^{-6}	9	0·58
Bemegride	10^{-6}	6	0·73
Adrenaline	10^{-6}	6	0·55
Noradrenaline	10^{-6}	6	0·63
Hyoscine	10^{-6}	9	0·84
Atropine	10^{-6}	6	0·79
Amphetamine sulphate	10^{-6}	9	0·61
Physostigmine	10^{-6}	6	0·54
Acetylcholine	10^{-6}	6	0·45

Although iproniazid, nialamid and acetazolamide, which are thought to act by the inhibition of an enzyme, did not stabilize the red cell membrane, the anticholinesterase physostigmine did produce moderate stabilization. There is a similar lack of correlation between membrane stabilization by drugs which are receptor blockers; propranalol, for example, does not exhibit a membrane protecting effect, while atropine and hyoscine do. Acetylcholine, adrenaline and noradrenaline, which can alter the physiological properties of the membranes of excitable cells, all produce a much smaller stabilizing influence of the red cell membrane than prenylamine and chlorpromazine. The stimulant drug bemegride also produces erythrocyte stabilization. In concentrations of 10^{-3}–10^{-4} M all the above drugs produced haemolysis; sucrose, however, did not cause either haemolysis or red cell membrane stabilization. These results indicate a general lack of correlation between inhibition of neuronal activity and red cell stabilization, particularly in the case of the pharmacologically active and inert barbiturates and in the stabilization produced by the central stimulant bemegride. The changes produced by a drug are, however, not likely to be the same in all types of membrane, and the effects on osmotic resistance may be different from the effects on resistance to chemical disruption[7]. Also some drugs, such as chlorpromazine, may act on a wide range of sites on the surface of membranes and in this way produce a marked change in the net physical properties of the membrane. Conversely, monoamine oxidase inhibitors, which react with only a limited number of membrane bound enzyme proteins, result in no detectable overall change in membrane resistance.

Effects of General Anaesthetics on Na^+ Transport in Human Red Cells

Theories of general anaesthesia have frequently been based on the suggestion that anaesthetic agents perturb the transport of ions through cell membranes[1,2]. In some theories, inhibition of transport has been invoked[3,4], whereas in others[5], facilitated transport in the presence of anaesthetics is proposed, but experimental evidence for either of these views is often contradictory. Anaesthetics have been observed to inhibit cation fluxes across nerve cell membranes during the transmission of impulses[6], and recently work on inverted frog skin preparations[7] and on the isolated toad bladder[8] has indicated that active cation transport may be affected by general anaesthetics. We have investigated the effect of ether and chloroform on active cation transport in human red cells.

The method is based on the well established observation that cold-stored erythrocytes lose K^+ and gain Na^+. On incubation in the appropriate medium the cells re-establish normal cation levels by active transport[9]. Cold-stored red cells were suspended in an active medium[10] and incubated at 37° C for 4 h, a period that gave rise to a conveniently measured change in cation concentrations. Subsequently the cells were quenched in ice, centrifuged, washed and after haemolysis analysed for haemoglobin, Na^+ and K^+. Experiments were carried out in the presence of various quantities of anaesthetics. The active and passive components of cation transport were resolved with the cardiac glycoside, ouabain, which in concentrations of 10^{-5} M is known effectively to eliminate active transport[11]. The results for one experiment with ether are illustrated in Fig. 1; the internal Na^+ concentration after 4 h incubation is plotted for various concentrations of ether in both the presence and absence of ouabain. The rise in intracellular Na^+ concentration and the degree of haemolysis of ouabain treated cells as a function of ether concentration are illustrated in Fig. 2; this indicates that both processes become significant at similar anaesthetic concentrations. The fall of internal K^+ concentration showed a similar pattern of behaviour. Experiments with chloroform exhibited the same trends that had been observed with ether. The concentration required to produce a 10 μequiv. ml.$^{-1}$ change in Na^+ concentration within red cells was 0·14 M for ether and 0·018 M for chloroform. Thus the concentrations of anaesthetics required to alter the rate of active cation transport significantly, to alter the rate of passive leakage of cations and also to produce significant haemolysis were considerably higher than the mean arterial blood concentrations occurring during clinical—stage 3—anaesthesia (0·013 M for ether[12] and 0·0016 M for chloroform[13]). These results indicate that no marked changes in the cation fluxes, active or passive, are induced by anaesthetics until a concentration is reached such that disruption of the membrane occurs, sufficiently gross to allow haemolysis though at lower concentrations there is some evidence of increased cationic transport. This, of course, does not conflict with the evidence that anaesthetics may influence the changes of permeability to Na^+ in the membranes of excitable tissues which accompany the action potential[1,6], or that anaesthetics modify the behaviour of erythrocytes in hypotonic conditions[14]. The results, however, must throw doubt on those theories of general anaesthesia which propose that anaesthetics act by their perturbation of the transport of cations through biological membranes in general[3-5,15-17], and suggest that the effects of general anaesthetics are more specific than have frequently been assumed.

Possible Mechanism of Action of Morphine on Brain

We have sought to extend previous studies[1-3] on the possible relationship between the effects of morphine on behaviour and alterations of biogenic amine metabolism. We propose that if morphine alters the metabolism of serotonin and catecholamines in brain, changing the relative amount of their free forms available for synaptic transmission and degradation, then depletion of the amines before administration of morphine should modify the effects of the narcotic on behaviour. The recent report by Way *et al.*[2] that depletion of brain serotonin inhibits the development of morphine tolerance in mice supports this proposal.

We chose the "spontaneous" motor activity of adult albino rats (Holtzmann strain) as the behavioural variable measured after a morphine challenge. A steel box 45 × 35 × 23 cm was constructed with a spring-loaded floor mounted over a piezoelectric transducer. The voltages from the latter were amplified, rectified and integrated at 10 min intervals. The score for each animal was read directly from the integrator. Daily activity runs were made to minimize emotional stress during final testing. Each group had equal numbers of males and females with average weights of 308 g and 205 g respectively. The drugs used in the pre-treatment are known to interfere with the metabolism of serotonin and/or catecholamines. We assumed that other possible effects were not critically involved, and this was partially borne out by some of the experiments. Two series of animals were used: rats which had not been previously exposed to morphine and which were therefore non-tolerant ("naive" series), and rats which had received 20 mg/kg/day of morphine sulphate for six days. This schedule, although not adequate to ensure tolerance to massive doses of the narcotic, was sufficient to eliminate the usual depressant action of a 10 mg/kg single dose of morphine in naive animals and replace it by a definite increase in motor activity. The experimental data are expressed in the tables as the average ratio of the post-injection activity (20 min after) to that estimated 10 min before the challenge dose of the narcotic for each treatment group. Thus a ratio above 1·0 represents an increase and below 1·0 a decrease in motor activity. All drugs were dissolved in 0·9 per cent saline—except α-methyl-*p*-tyrosine (AMPT) and *p*-chlorophenylalanine (PCPA) which were given in a steroid suspension vehicle[4]—and injected intraperitoneally. The control groups received saline or the suspension vehicle alone.

Table 1. EFFECT OF MORPHINE CHALLENGE (20 mg/kg) ON SPONTANEOUS MOTOR ACTIVITY AFTER VARIOUS PRE-TREATMENTS: NAIVE RATS

Pre-treatment	Dose (mg/kg/day)	No.	Mean ratio: post/pre-injection	P†
Controls*		16	0·18	—
PCPA	300	8	3·14	< 0·01
PCPA + 5-hydroxytryptophan	300 100	4	0·35	> 0·05
5-Hydroxytryptophan	50–100	11	0·73	> 0·05
Iproniazid	50	4	0·81	< 0·03

* No difference in ratios was found between the saline and solvent pre-treated controls in both series. These groups were therefore combined.

† All P values refer to comparisons with the control group, according to the two tailed Mann-Whitney U test.

Table 2. EFFECT OF MORPHINE CHALLENGE (10 mg/kg) ON SPONTANEOUS MOTOR ACTIVITY AFTER VARIOUS PRE-TREATMENTS: TOLERANT RATS

Pre-treatment	Dose (mg/kg/day)	No.	Mean ratio: post/pre-injection	P
Controls		8	4·20	—
AMPT	80	8	1·40	< 0·03
AMPT + L-DOPA	80 100	4	10·00 +	< 0·01
Diethyldithiocarbamate	500	8	1·81	< 0·04
Imipramine	25	4	0·44	< 0·01

PCPA, which inhibits the hydroxylation of tryptophan—the rate-limiting reaction in the synthesis of serotonin[5]—was administered to "naive" rats to determine whether previous depletion of serotonin from brain would modify the depression induced by morphine. Rats were injected three times per day with PCPA (300 mg/kg/day) and then challenged with a single dose of morphine (20 mg/kg) on the sixth day after the first dose of PCPA. Controls which received solvent were severely depressed by morphine; the rats which had received PCPA were clearly excited by the narcotic (Table 1). The specificity of this effect of PCPA was shown by administering 5-hydroxytryptophan[5] concurrently with the PCPA in another group of animals. These were depressed by morphine. 5-Hydroxytryptophan alone (either 50 or 100 mg/kg in different rats) as well as a monoamine oxidase inhibitor (iproniazid), injected daily for five days before challenge with morphine, reduced slightly the depressant effect of the morphine compared with parallel saline control groups. The last injection of both 5-hydroxytryptophan and iproniazid preceded the morphine challenge by at least 24 h.

The "tolerant" series (Table 2) was used chiefly to study the effects of manipulation of catecholamine levels on the response to morphine. The control tolerant animals for this series were prepared by injection of 20 mg/kg/day of morphine for six days. These rats were markedly excited by a 10 mg/kg dose of morphine whereas non-tolerant animals were depressed by the same challenge. A priming injection of 20 mg/kg of morphine was given to all the animals in this series 4 h before the final test, to minimize the possibility that abstinence phenomena might interfere with our results. AMPT is known to inhibit the hydroxylation of tyrosine into L-3,4-dihydroxyphenylalanine (L-DOPA), the rate limiting reaction in the synthesis of dopamine and norepinephrine. Its effect is therefore the depletion of these amines from brain and other tissues[6]. Two injections of AMPT within the last 24 h of the experiment, 12 h apart, prevented the excitation induced in tolerant rats by the morphine challenge. Administration of L-DOPA 1 h before the challenge, in an otherwise identical AMPT-treated group, reversed the effect of AMPT, so that clear-cut excitement was produced by the narcotic. Diethyldithiocarbamate has been shown to block the β-hydroxylation of dopamine into norepinephrine[7]. Injection of this agent 4 h before a challenge with morphine, also in tolerant rats, reduced the excitation induced by the challenge. Finally, imipramine—which apparently exerts some of its effects on behaviour by interfering with re-uptake of norepinephrine into its storage form[8]—given 2 h before testing, also prevented the motor hyperactivity induced by morphine.

We conclude that at least some of the behavioural effects of morphine administration can be reversed by pre-treatment with drugs which affect biogenic amine metabolism. The specificity of some of these effects was demonstrated by their elimination when amine precursors (5-hydroxytryptophan and L-DOPA) were administered in conjunction with PCPA and AMPT, respectively. While no gross alterations of total biogenic amine levels have been found to result from single or multiple doses of morphine[9,10], the evidence for morphine-induced alterations in amine turnover rates is rather definite. Thus Gunne[1] and Haubrich and Blake[11] have shown that the brain levels and the urinary excretion of 5-hydroxyindoleacetic acid and of catecholamine metabolites are increased substantially after administration of morphine, and Way *et al.* have shown increased accumulation of serotonin in morphinized animals treated with a monoamine oxidase inhibitor, compared with non-morphine treated controls[2]. If increases in rate of turnover—rather than increases in the total (free and stored) levels—of the amines are the consequence of morphine treatment, two possible conclusions are suggested. Either the activities of rate-limiting enzymes concerned in the synthesis of the amines increase following morphine or, perhaps more likely, amine re-uptake into storage forms[12,13] is impeded by morphine, thus increasing the amount of free amines available for synaptic transmission and metabolic degradation. Recent reports on the antagonism between reserpine and morphine[14,15] and the interference we have found between imipramine and morphine support the second alternative, which also requires fewer assumptions. We now plan to test this hypothesis directly. If morphine is indeed found to interfere significantly with the uptake of serotonin and norepinephrine, our behavioural results would lead us to expect differences in the degree and duration of this interference, to account for the well known differences in the effects of morphine in tolerant and non-tolerant animals.

Schizophrenia as a Genetic Morphism

THE incidence of schizophrenia in most communities is of the order of 1 per cent. Yet the fertility of schizophrenic males is low, as noted by Huxley *et al.*[1]; and it has since been established that the fertility of schizophrenic females is low, too[2]. The second observation serves to strengthen the suggestion of Huxley *et al.* that the fertility of schizophrenics seems too low for the disorder to be maintained at its present rate by mutation alone. In explanation they noted the resistance of schizophrenics to surgical and wound shock, to visceral perforation, to high doses of histamine, insulin and thyroxine, and to pain. They noted also the possibility that schizophrenics may be resistant to diseases such as smallpox and bubonic plague which have occurred in widespread epidemics.

Moran[3] suggested that the proposed robustness of the schizophrenic genotype might be manifested at an earlier stage of life: "I therefore suggest that the presence of a gene for schizophrenia has a protective effect for one or more of the genetic factors which cause the loss of fertilized ova".

It may be worth noting that the only two relevant studies known to me do not support Moran on this point. These suggested that, in contrast with control samples, there was a higher incidence of foetal loss among the sibs of schizophrenic propositi[4], and that there was a higher proportion of miscarriages among the pregnancies of psychotic women (64 per cent of whom had been diagnosed as schizophrenic)[5].

There are two problems about the incidence of schizophrenia: in the first place it seems very high, and in the second it seems not to be declining (as it should be if a schizophrenic gene protected its bearer against bubonic plague or smallpox). I can offer no fresh answer to the first. In regard to the second, it seems possible to me that either the level of schizophrenia is being maintained by an increasing degree of psychological stress to which we are said to be exposed, or that a true decline in schizophrenic rates is being masked by less extreme criteria of definition. Possibly one does not have to be so mad these days to be called "schizophrenic".

Possible Relationships between Orienting and Diving Reflexes

THE diving reflex has been studied extensively in aquatic organisms that breathe air and submerge to obtain food or to escape from predators such as ducks, seals and alligators[1]. This reflex seems to have two phases: an initial phase which may be mediated by the vagus and trigeminal nerves[2], and a later one which follows prolonged holding of the breath during voluntary or forcible submersion[3]. The initial phase includes bradycardia[1,4], apnoea (specifically, an interruption of respiration)[1,4], peripheral vasoconstriction[4,5] and cephalic vasodilation[5]. Gaunt and Gans[6] have reported that bradycardia in *Caiman crocolilius* is minimal during spontaneous dives but great during the approach of an investigator or during handling. They suggest that early diving bradycardia is mainly "psychogenic" in origin and results from "threatening" stimuli. We have been studying (ref. 7 and unpublished results) the responses of the wholly aquatic salamander *Necturus maculosus* (mudpuppy) and have noted similarities to the early components of diving, specifically bradycardia and an interruption of respiration. (*Necturus* breathes through

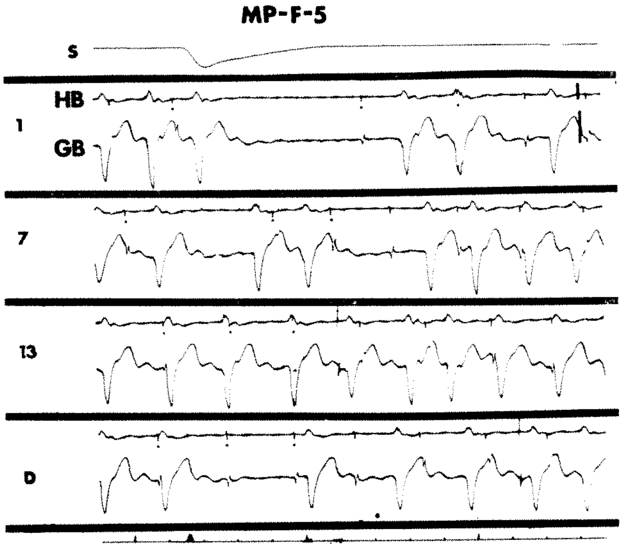

Fig. 1. The effect of repeated shadow stimulation on heart beat (HB) and gill beat (GB) in one animal. Passage of the shadow was recorded by a photocell on the aquarium (S). Initial shadow presentation (1) produced bradycardia and apnoea seen first as an interruption for about 4 s, followed by resumption at a slower and more variable rate. Repeated shadow presentation (at approximately 120 s intervals for this animal) led to a decrement in the degree of bradycardia and apnoea (trial 7) and finally to no effect (trial 13). The apnoea was reinstituted by changing the shadow direction (D). Heart beats immediately before, during and after the shadow are denoted by dots. Bandpass: HB, 15–75 Hz; GB, 1–75 Hz. Calibrations, 10 μV and 1 s.

large external gills beating back and forth at 0·5–1·0 beats/s.) Insofar as it does not dive, we suggest here that these responses of *Necturus* are components of the orienting reflex[8,9] rather than the initial diving reflex, and that both reflexes may reflect some common neural substrate involving adaptive responses to external stimulation.

Necturus maculosus obtained from a commercial dealer were kept and tested in water at 19° C. Sixty animals were tested singly in a 'Plexiglas' aquarium, 28 × 12 × 6 cm, housed in a refrigerator. Dim illumination (2·5 foot lamberts at the aquarium) was provided by a parallel array of six luminescent strips (Sylvania 'Tape-Lite' *PTL* 175) mounted 30 cm above the aquarium. The illusion of a moving shadow was created over the aquarium by sequentially interrupting current to each strip with silent solid state circuitry[10]. The shadow velocity was 0·11 m/s. Respiration (gill beating) and heart beat were recorded, without affixing leads to the animal, by stainless steel studs (5 mm diameter) embedded in the sides of the aquarium below the surface. Voltages generated by water waves after gill beating, and EKGs recorded by volume conduction, were recorded via high gain differential amplifiers on a polygraph. We shall give a complete validation of the recording technique elsewhere (see also ref. 7). It has the advantage of working without sensors or restraint of the subject. One limitation is that gill and heart beats may be obscured during large movements, although the movements are revealed by their own characteristic voltages following water turbulence. Our data came from quiescent animals.

The animals equilibrated for at least 24 h before the shadow was first presented. After the first stimulus, respiration was interrupted, as could be seen from the cessation of gill beat in all animals, and bradycardia in 83 per cent, seen at first as one or more "skipped" beats. Periodic presentation (30–400 s) of the stimulus evoked the same responses but with less vigour, until neither apnoea nor bradycardia occurred (Fig. 1). We interpreted the waning response as habituation, because apnoea and bradycardia can be brought back by a fresh stimulus such as reversing the direction of the shadow or applying vibration rather than shadow. Extensive investigations of other parameters, such as the interval between trials, confirmed the interpretation of habituation[7,11]. Response habituation is characteristic of the orienting reflex[8,9]. Interestingly, the orienting reflex includes the same characteristics as the early phase of the diving reflex: bradycardia[12], apnoea[13], peripheral vasoconstriction[9] and cephalic vasodilation[9,14]. These and other similarities between the early phase of diving and the orienting reflex are summarized in Table 1, in which the duck and mudpuppy are compared. While some data are lacking, the close similarity of the reflexes seems obvious. We do not suggest that the initial phase of the diving reflex is identical to the orienting reflex, although it would be interesting to know whether any of the early components of "spontaneous" diving exhibits habituation.

Belkin[15] has suggested that components of the diving reflex may have evolved as specializations from physiological responses to more general situations of external stimulation of an animal. *Necturus* occupies an evolutionary position in which components of the orienting response might include such primitive physiological responses. If the diving and orienting reflexes are so related they may be expected to have closely related neural substrates. We note that stimulating the midbrain produces components of the initial diving reflex and the orienting reflex[16,17]; components of both reflexes have been elicited also from the amygdaloid nucleus[16,18,19]. It would seem that the diving and orienting reflexes have enough in common to justify further thought on their interrelation.

Reproductive Cycle of a Neotropical Insectivorous Bat, *Myotis nigricans*

REPRODUCTIVE patterns in bats fall into three main categories. A synchronous breeding season and monoestry is common in all holarctic bats[1]. Continual asynchronous breeding is found in some tropical bats of the families Desmodontidae[2], Phyllostomatidae[3], Pteropodidae, Emballonuridae and Molossidae[4]. In some palaeotropical bats seasonal polyoestry is the rule, with two synchronized breeding seasons each year[4,5].

Because of the rigorous environment of the temperate zone, parturition in holarctic bats is largely limited to May, June and July, when temperatures are mild and food is abundant. Most of these temperate zone bats belong to the insectivorous family Vespertilionidae. Neotropical bats which breed continually are either sanguivorous or frugivorous and are probably never exposed to a shortage of food[6].

Myotis nigricans, the first neotropical Vespertilionid whose reproduction has been studied, has a fourth type of reproductive cycle. These bats breed continually during most of the year but become reproductively quiescent for about 3 months during the latter part of the rainy season (Fig. 1).

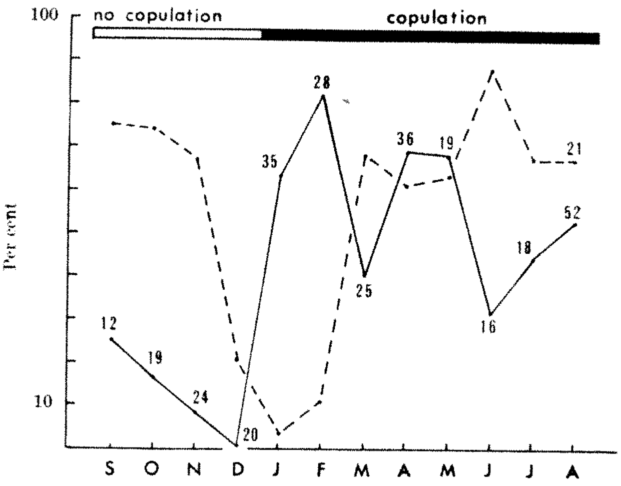

Fig. 1. Percentage of pregnant (———) and lactating (- - -) females in one year. The numbers are sample sizes.

We examined reproductive tracts of more than five hundred *M. nigricans* from September 1968 to September 1969. Animals were collected at weekly intervals from roosts on Barro Colorado Island and the nearby town of Gamboa, Canal Zone. Pregnant females were taken in every month of the year except December. In November only a few pregnancies were noted, and all of those were near term in the first week of the month. After a 7 week period with no pregnancies, 63 per cent of the females collected during January were found to be pregnant. The first pregnancies were noted on January 3 and parturition began in the last week of February. This and subsequent observations lead us to believe that the gestation period for *M. nigricans* is near the 50–60 days reported for other members of the genus[7]. The three pregnancy peaks are about 3 months apart and our observations show that this is about the time needed for gestation and lactation of one litter. The animals tend to become less synchronized as the year proceeds, as shown by the fact that the peaks become progressively shorter, and there is always a certain number of pregnancies at any given time.

The curve for lactation is similar to that for pregnancy, but, of course, shows a time lag of one to two months. The total of the two percentages is sometimes more than one hundred, indicating animals that are both pregnant and lactating. Evidence for polyoestry consists of numerous individuals that were both pregnant and lactating, as well as continuous observations of banded individuals which produced at least two young during the year. This indicates post-partum oestrus at least occasionally, and we feel from other observations that it is the rule. This is the first conclusively demonstrated instance of polyoestry in the family Vespertilionidae, although there is suggestive evidence of its occurrence in a few Old World species of the genus *Pipistrellus*[5,7].

If the gestation period is less than 60 days, it is hypothetically possible for a given female to produce four young in a year. We feel that because of individual variation in times of copulation, ovulation, fertilization, gestation period and post-partum oestrus, three is a more usual number.

The fact that no young are produced from December to March may relate to seasonality of the food supply. During the dry season (January–March), insect populations are probably lower than at other times of the year[8]. There is usually an insect bloom in April when the rains begin. It seems that the strategy of the bats is to wean the young at this time of year and to avoid weaning young at times of lowered food supply. Copulation must therefore cease around the middle of September, and the last young of the year are born in November and weaned in December. Copulation begins again in January (we observed it many times). The first young are born in March and weaned in April. The cues for this cycle are as yet unknown, but the critical times are September and December, so that temperature and rainfall would seem to be extremely unlikely. Photoperiod is a possibility, but changes at this latitude are slight (1 h and 3 min from summer solstice to winter solstice).

Acoustic Basis for Individual Recognition by Voice in the Gannet

A RECENT article by W. H. T.[1] reviewed the general question of the perceptual basis for group organization by birds and other vertebrates. It pointed out that successful social organization of colonially nesting sea birds must in many cases depend on a capacity for mutual recognition at some distance, at least between mates and also between parents and young, perhaps extending to other members of the group. While many species of birds (such as gulls and ducks) have visual powers so acute that they are able to recognize individuals at distances of 50 m or more, it was nevertheless shown that auditory recognition of individuals by subtle voice characteristics also plays a part—sometimes major—in identification. Indeed, in some examples of gulls, penguins, auks and terns, the evidence suggests that audio-vocal recognition is likely to be more effective in the difficult conditions of life in a dense breeding colony than is visual recognition. As an example, work on the sandwich tern (*Sterna sandvicensis*)[2] has shown in some detail that the individual vocal patterns are constant and can be distinctively categorized in terms of a pattern of energy distribution expressed as frequency against time, which is so well shown by the spectrograph. This kind of pattern is, of course, what we ourselves hear as organized sounds with their characteristic temporal arrangement and tonal quality, as in speech or music.

Our object here is briefly to summarize some interesting new findings with gannets (*Sula bassana*); a full account is in the press[3]. The interesting features are that the usual frequency-time parameters were of little use in analysing individual vocal features; instead, changes in the amplitude envelope were used. Further, the first part of each call was sufficient to give individual information.

Until recently, the most extensive work on the individuality of sounds has dealt with humans. A great many experiments suggest that amplitude fluctuations of speech are relatively unimportant and, indeed, may be removed electronically without seriously affecting intelligibility[4]. Computer recognition of individual speech shows that frequency-time parameters are more useful than amplitude characteristics[5]. In the gannet, amplitude changes are highly individual, though whether the birds themselves use this characteristic has not yet been tested. (Playback experiments, to be described in a subsequent paper, were made using only the whole calls—to which the birds do respond.) We have other observations, however, which would suggest that amplitude changes may be important. Thus sandwich tern calls, which have been shown to be individual from other measures, have been analysed for amplitude characteristics and show marked individuality (unpublished observation). Whether this phenomenon is general among birds remains to be seen.

We made recordings for a month from a small colony of known individual gannets on the Bass Rock (Firth of Forth, East Lothian, Scotland). The calls were subsequently analysed on a sound spectrograph with an amplitude display attachment. The typical landing calls of the gannet are shown as standard sonograms in Fig. 1. Both gross timing analysis (wide band sonograms, Fig. 1*a*) and gross frequency analysis (narrow band sonograms, Fig. 1*b*) show considerable overlap between individuals and are obviously not useful in making any individual identifications. The measure which did show consistent individual features is shown in Fig. 2, which depicts the amplitude of the sound envelope as a function of time. It should be obvious from this figure that the consistency resides in the first few peaks and troughs. The observations were sufficiently encouraging to warrant a more precise method of measurement.

One of the drawbacks of the amplitude display device is a slow response time, so that slowing down the sound gives a better picture of any fine detail, and in the final analysis we used the calls at half speed. With a curve tracer, readings of the log amplitude were obtained from each call at millimetre intervals, taking the sonogram baseline as 0. Each millimetre interval corresponded to 0·005 s in real time, and the number of intervals involved will be referred to here as N. By aligning the calls at the lowest point of the first major trough, all component calls in a sequence were averaged to give a single numerical "profile" of a complete call; each ordinate of the final profile was therefore an average of the log amplitudes at corresponding millimetre intervals. The profiles obtained were checked by replotting them on to graph tracing paper for comparison with the original calls; the fit was usually very good. At half speed, the length of the calls varied from $N = 55$ to $N = 100$. To reduce the amount of information and expedite subsequent analysis, the profiles were cut to the length of the shortest ($N = 55$).

Matching was subsequently done by a computer using linear correlation[5] (Pearson's correlation coefficient, r_p) as a measure of similarity. In the manner described above, we obtained three profiles for each of nine different males, and two from another, each representing calls uttered on separate occasions. (Female calls were not investigated at this time.) One profile of each male was chosen, at random, as a reference sound. These ten references (Fig. 3) were stored in the computer; each of the remaining profiles (sample sounds) was then compared with the list to see with which reference it matched best. Matching consisted of calculating r_p for the sample against each of the references. The sample was said to match with the reference that gave the highest r_p, regardless of

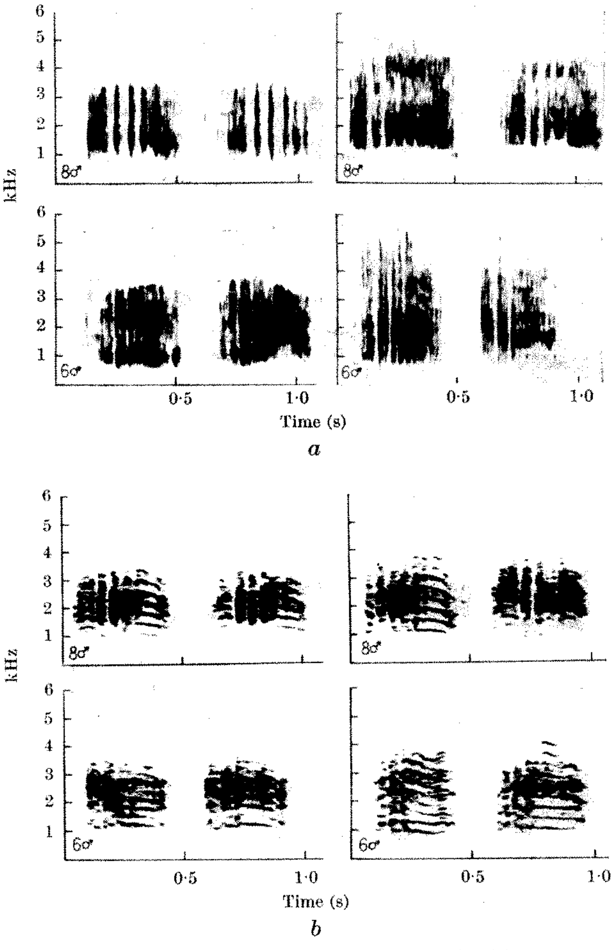

Fig. 1. Landing calls of two male gannets uttered on two separate occasions. (A full landing sequence may contain from six to more than twelve calls.) *a*, Wide band sonograms—normal speed (7·5 inches/s); *b*, narrow band sonograms—normal speed.

May we introduce you to an interesting Polish periodical entitled

ARCHIVUM IMMUNOLOGIAE ET THERAPIAE EXPERIMENTALIS

Published by the Institute of Immunology and Experimental Therapy of the Polish Academy of Sciences. It publishes the works of Polish and Foreign scientists undertaking experimental research in the fields of immunology, microbiology, virology, hematology, experimental oncology, chemical therapy and biochemistry. Published bimonthly. Articles in English. Annual subscription £12.10.0.
Subscription orders are received by local foreign press distributors or

Thermal Neutron Diffraction

Edited by B. T. M. Willis

This book is based on papers presented at an international summer school held at Harwell in July 1968 on Accuracy in Neutron Diffraction. Recent research on the magnetic and nuclear elastic scattering of thermal neutrons is reviewed by leading workers in the field. This work has led to new information on the electronic and nuclear charge distributions in solids, and the book should therefore be of interest to crystallographers, solid-state physicists, and chemists. 130 text figures paper covers 65/-

Mind, Brain and Adaptation in the Nineteenth Century

Cerebral Localization and its Biological Context from Gall to Ferrier

Robert M. Young

The author examines ideas of the nature and localization of the functions of the brain in the light of the philosophical constraints at work in the sciences of mind and brain in the nineteenth century. He pays particular attention to the phrenology, sensory-motor physiology, associationist psychology, and the theory of evolution as applied to the study of psychology. 1 text figure 65/-

The Collected Papers of G. H. Hardy

Including Joint Papers with
J. E. Littlewood and others

VOLUME IV

Edited by a Committee appointed by the London Mathematical Society

The main object of this publication is to render more accessible the papers of the great mathematician, which in their original form appeared in many journals over a period of almost sixty years. Frontispiece £6

The Biology of Pseudoscorpions

Peter Weygoldt

This is the first comprehensive treatment of the biology of pseudoscorpions. Published in Germany in 1966, it has been translated by the author and expanded to include his observations from a recent trip to the United States.
Mr. Weygoldt shows that, although pseudoscorpions seem to be a uniform group of average arachnids, closer study reveals the diversity of their reproductive and developmental biology, their ecology and their behaviour

MATHEMATICS...

Two New Texts from W. B. SAUNDERS Co. Ltd.

Epstein:

LINEAR FUNCTIONAL ANALYSIS

This new book provides a first look at linear functional analysis in which the abstract concepts are preceded by the study of non-trivial concrete problems. Once abstract methods are developed they are used to solve some classical problems. Some topics receiving special attention are: measure and integration; integral equations; estimation of eigenvalues of Hermitian kernels; L^2 theory of Fourier transforms. Accessible, as a text or reference, to university students in mathematics, applied mathematics, physics and mathematical engineering.

CONTENTS:
Metric Spaces—Lebesgue Measure and Integration—The L^p and l^p Spaces—Normed Linear Space—Linear Functionals—Linear Transformations and Operators—Operators on Finite-Dimensional Spaces—Elements of Spectral Theory in Infinite-Dimensional Hilbert Spaces.

229 pages. Illustrated. February 1970 £4 1s. 0d.

By: Bernard Epstein, *Professor of Mathematics, University of New Mexico.*

Ballard:

GEOMETRY

A mathematically substantial textbook in geometry which rests on some metric concepts. This assumption of some metric axioms provides relative unity with other mathematics familiar to beginning university and advanced secondary school students.

CONTENTS:
Points, Lines, and Planes—Distance and Betweenness—Convexity and Separation—Degree Measure—Congruence of Triangles—More about Triangles; Some Inequalities—Parallels and Similarity—Circles—Space Figures—Area and Volume—Measurement—Co-ordinate Geometry of the Plane—Spheres—Euclid's Parallel Postulate—The Theorem of Desargues—Axiom Systems for Euclidean Geometry—Finite Geometries—Pythagorean Triples—Cardinal Numbers—The Jordan Curve Theorem.

By: William R. Ballard, *Department of Mathematics, University of Montana*

238 pages. 178 illustrations. February 1970 £3 16s. 6d.

its absolute value. This identifying procedure was replicated using progressively shorter sounds (by reducing N) to test the suggestion arrived at when matching the displays by eye: that the most characteristic parts were the first few peaks and troughs. A matching "session" was ended when a sample sound no longer matched its own reference.

The results of these analyses are shown diagrammatically in Fig. 4, where intervals along the horizontal axis represent reference sounds and intervals on the vertical axis represent the sample sounds; corresponding intervals on the two axes are associated with the same male. If the achieved match is shown by a blackened triangle, then, with perfect matching, one would expect a diagonal of black squares (except in the case of male 10, which had only one sample sound). The figure shows that as N decreases, there are very few errors in matching until $N = 30$, by which time there are three mis-matches. At $N = 25$ and below, identification becomes more difficult. (Compare this with Fig. 3, which shows, for each reference, the smallest amount of that profile which was necessary to maintain identity with one of its own sample sounds.) Because the technique is essentially one of pattern matching, it is not surprising that where confusions did occur (for example, males 3 and 4), they were between shapes that were subjectively the most similar. (In this sense linear correlation, which gives as much weight to similarities as to differences, may not be the most sensitive statistical test to use. Moreover, the eye does not operate that way.) These results do, however, confirm our suggestion that gannets have individual calls and, further, that there is enough information in the beginning parts of each call to distinguish one individual from another.

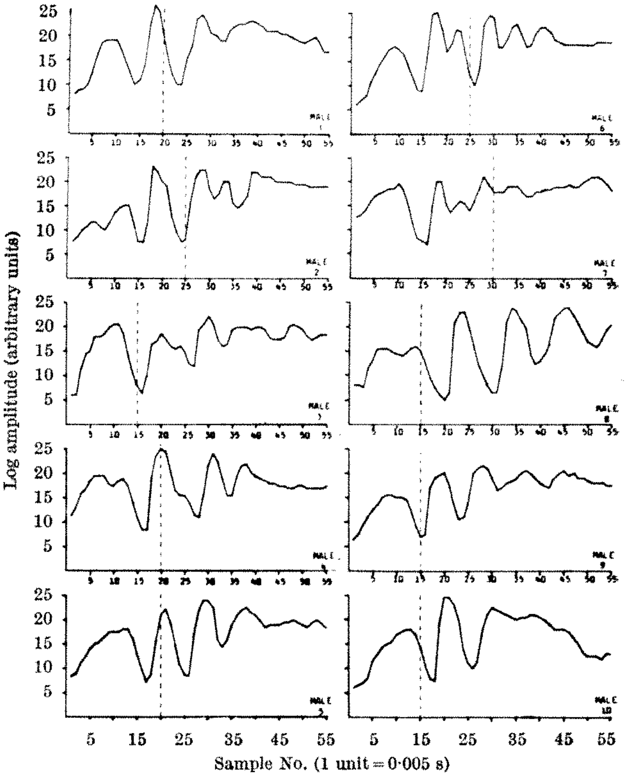

Fig. 3. The reference profiles with which the sample profiles were correlated. Dotted lines show the smallest amount of that sound which was necessary to match with one of its own sample sounds.

If there is enough information in the first part of the call to identify the caller, what is the function of the end part? It is probably worth noting that we are restricting our questions by looking merely for individuality in a call; the call of an incoming bird could well carry much more information than its identity. But it makes intuitive sense that the identifying part of a call should be at the beginning (after comparatively long periods of silence) so that sitting individuals, who probably pay low level attention to all sounds coming from the proper direction, can receive individual information efficiently. The differences we have found do, however, depend to some extent on the method of analysis we have chosen (amplitude detection), and it might be that the sounds are individually different in a number of ways. This is not surprising, for one might expect that any sound selected to be individually recognizable in noisy conditions would show its uniqueness in a number of ways. The envelope amplitude was the most obvious feature to us and then, primarily, in the first parts of the call. It may also be that information is coded differently in different parts of the sound. So, for example, the lack of consistent detail in the amplitude tracings above $N = 30$, which is also shown by the lack of improvement in matching above that N, might occur because a different kind of information is present. If differences in frequency were important here, our analysis method would not find them. A few sounds examined on an oscillograph, which has a fast response time, did suggest some consistent detail in the end regions of the call as well, but this was not as regular a feature as the beginning parts (see Fig. 2).

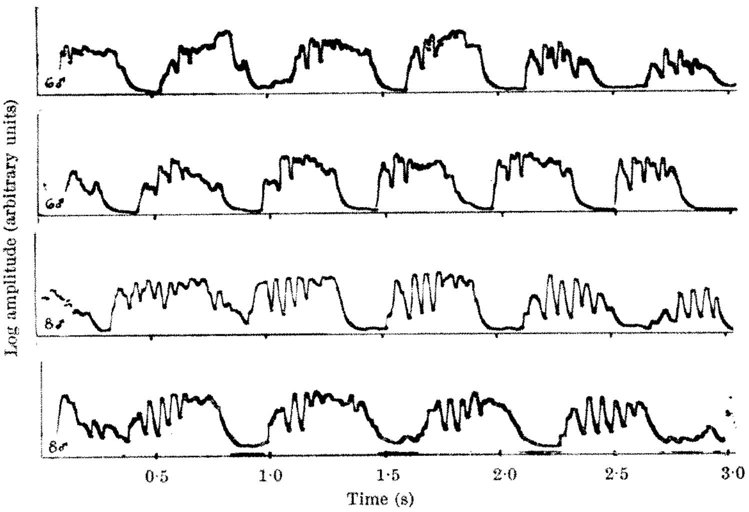

Fig. 2. Amplitude displays of landing calls of two male gannets; each call was uttered on a separate occasion. Normal speed (7·5 inches/s).

Our work tells us very little about how gannets themselves perceive sound. They would presumably make use of as much information as possible. Sea birds present interesting acoustical problems in that their environment is extremely noisy and they usually call while in flight. In conditions of movement and noise, what would be the most effective signal? One possibility is that intermittent signals, such as those given by the gannets, might be very easy to localize. Sitting birds do not appear to be searching for their absent mates. Birds tend to approach their colony up-wind, however, diverging towards their particular nests only when they are some yards away. So an incoming bird might well be identified by its line of flight as well as by any individuality of voice. The impulsive nature of the beginning of each call probably makes accurate localization easier, and by tracking approaching sources of sound, a sitting bird might quickly detect one which was approaching its nest and, at the same time, gain further information from the individual structure at the beginning of each call. Birds have an acute temporal sense[6] and individuality might reside less

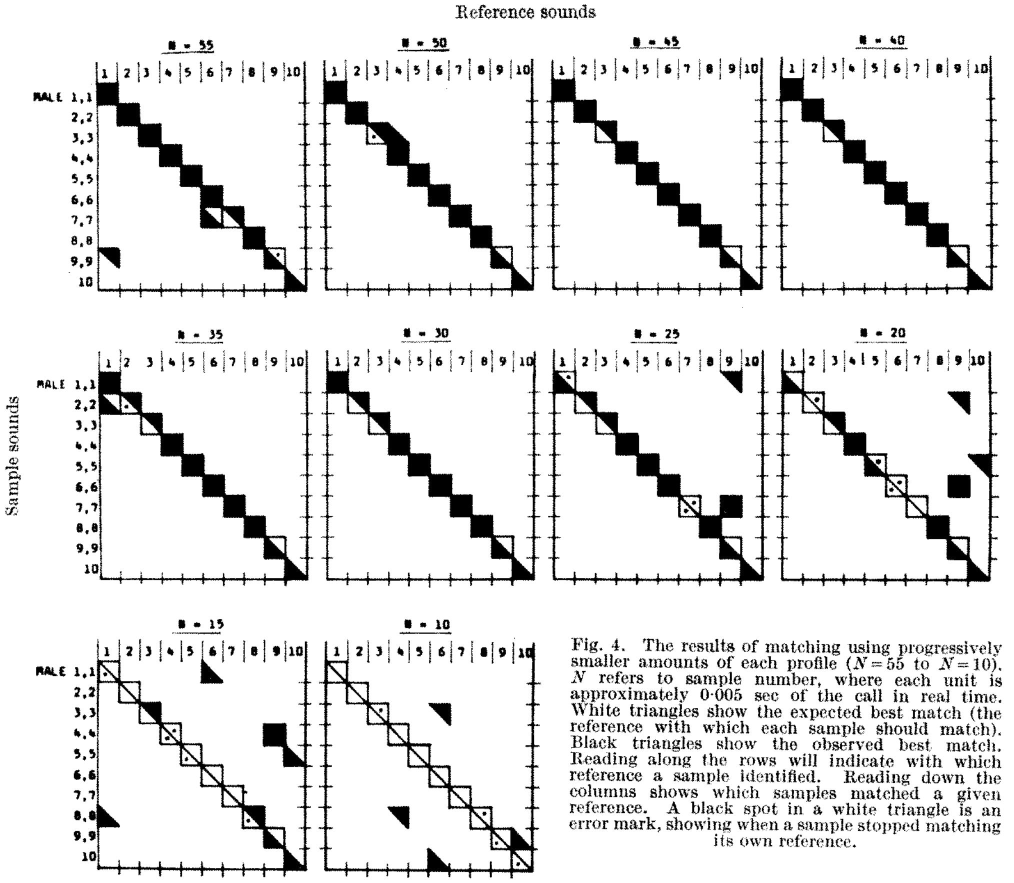

Fig. 4. The results of matching using progressively smaller amounts of each profile ($N = 55$ to $N = 10$). N refers to sample number, where each unit is approximately 0·005 sec of the call in real time. White triangles show the expected best match (the reference with which each sample should match). Black triangles show the observed best match. Reading along the rows will indicate with which reference a sample identified. Reading down the columns shows which samples matched a given reference. A black spot in a white triangle is an error mark, showing when a sample stopped matching its own reference.

in the amplitude *per se* than in its temporal patterning as a series of impulses. Further, because the amplitude envelope of the calls can be both averaged and cross-correlated, it would follow that they vary regularly in time.

Birds discriminate frequency as well as humans[6] and have a finer temporal sense. How well they perceive amplitude is not known. If amplitude were perceived, what possible function could it have? One speculation could be that it provides a way of accommodating for changes resulting from movement. There are changes in the temporal structure of sound in proportion to the rate of movement of its source (the Doppler effect). It follows that all sound frequencies received are also changed. This would mean that the frequency and time structure of an approaching bird's calls would be heard with a more or less constant shift from their true values, the shift depending on its speed of approach. Amplitude would, however, change only gradually as the bird came nearer. Whether birds are capable of discriminating these changes has yet to be tested.

We wish to make two further points about the use of such techniques. First, not only is the question of individuality of voice production interesting in itself, but it could be used as a fruitful approach to the question of bird perception. That is to say, by analysing those features which make calls distinctive, one goes a step towards effective testing of what the animal is capable of hearing. Sound manipulation and playback would, of course, be the next step. Second, developing techniques for readily identifying individuals on the basis of their sounds would make certain types of field work possible. For example, in conditions where physical marking of individual animals may be difficult or disruptive, or where it is not always possible to see the animals easily, voice-tagging might be most helpful. Further, if reliable voice identification were possible, it might make possible "blind" experiments in the field, with subsequent identification of individuals in the laboratory.

Faunal Provinces in the Ordovician of North Atlantic Areas

WILLIAMS[1] has recently pointed out a number of quantitatively significant relationships between Ordovician brachiopod faunas on both sides of the Atlantic. In the Early Ordovician and the early stages of the Middle Ordovician three brachiopod faunal provinces persisted in the area of the British Isles. The provinces occurred as belts in the NE–SW strike direction of the Caledonian geosyncline. Along the northern margin of the geosyncline, extending through NW Ireland and Scotland, there was a province with mainly North American faunal affinities (American Province). Williams suggests that the migration of the brachiopods in this province took place by a current transporting the brachiopod spat towards the NE. The central part of the geosyncline was occupied by anaerobic bottoms with graptolitic mud, devoid of significant brachiopod fauna. South of this belt there was a strip extending through SE Ireland and NW Wales (Anglesey), in which the Lower–Middle Ordovician brachiopod faunas are most closely related to stratigraphically equivalent faunas of the Baltic area (Baltic Province). Williams shows that these faunas probably spread with a current system flowing towards the SW. The same current system was responsible for the migration of the Anglo-Welsh fauna occupying the southern marginal area of the geosyncline.

The fairly precise model sketched above was stated by its author to be based exclusively on brachiopods. This limitation is not as serious as it might seem at first, for brachiopods are in many cases the dominant faunal elements. They are greatly diversified and have been subjected to intensive study by many authors in different countries. Within the well aerated, current-swept realms of sedimentation to which they must have been restricted even in the Ordovician, they seem to have been relatively free in their choice of sedimentary substrate.

It was thus a reasonable starting hypothesis that brachiopod faunal provinces were separated by geographic barriers such as different current systems, rather than by purely ecological control. Evidence from the distribution of genera of graptolites and trilobites does not seem to offer any essential contradiction to this model.

The concept developed by Williams has been sketched in some detail because it will be shown how the conodonts fit into the picture. Our knowledge of conodont distribution in the Ordovician on both sides of the Atlantic is too fragmentary for detailed reconstructions of the palaeogeography to be founded on conodonts alone. They might, however, help in the interpretation of distributions of other faunal elements. One serious limitation is that the mode of life of the conodonts is as unknown as their precise place in the animal kingdom. What we do know is that they were marine animals with an unusual spreading ability. Further, they were independent of substrate to a greater extent than any other well-known group of fossil animals.

In the Arenigian, the first of four stratigraphic intervals discussed by Williams, a Baltic conodont fauna was found by Lamont and Lindström[2] in the southern uplands of Scotland—that is, within or adjacent to the American Province of Williams. Twenty-two species were listed. Because present knowledge about conodont apparatuses consists of several different-looking elements, the number of species has to be reduced to sixteen. Four elements were identified with some doubt. The rest of the fauna is beautifully preserved, and conspecific with forms that occur in the Billingen substage (BI_{ss}) of the Lower Arenigian Latorp stage all over the Baltic Shield. Until now this fauna has not been found in North America. American faunas that are roughly contemporary seem to be characterized by a number of panderodonts (in the widest sense, including *Acanthodus*) that have not been found in Europe. The easternmost recorded occurrence of *Acanthodus* is near Chambersburg in southern Pennsylvania[3].

The same fauna contains *Loxodus*, which is highly characteristic and is another North American element that has not been found in Europe in spite of intensive and extensive collecting. The genus *Cordylodus* found in the same section was cosmopolitan in the Tremadocian but is absent in most Arenigian faunas in Europe.

In the Llandeilian to basal Caradocian, which is close to another interval discussed by Williams, the belt from southern Scandinavia through Scotland to the Appalachians has a characteristic conodont fauna consisting of *Periodon*, *Pygodus*, *Cordylodus spinatus* Hadding, and coarse, costate forms related to *Drepanodus* s.str.[2,4-6]. Elements of this fauna only rarely transgressed into the American Midcontinent[7]. Conversely, Llandeilian conodont faunas recovered from Wales have strong affinities to certain Midcontinent faunas[8]. During the Caradocian the provincial boundaries tended to become less sharp.

Current system suggested in principle by A.Williams.[1]

Fig. 1. The American and European continents in an arbitrary relative position suggesting some continental drift.

It would clearly be impossible to derive a simple and consistent current system from the distribution of brachiopods and conodonts. Using the conodonts alone might turn out to be more misleading than using the brachiopods. But the conodont evidence, scant though it is, proves that the current pattern explaining the distribution of brachiopods in the Ordovician has to be modified to fit the real case. Ecological control of faunal distribution should perhaps also be considered more seriously.

Hybrid Vigour in Seedlings of Re-created London Plane

THE London plane (*Platanus* × *acerifolia* (Ait.) Willd. = *P.* × *hispanica* Muenchh.) has long been regarded as an accidental hybrid between the oriental plane (*P. orientalis* L.) and the American plane (*P. occidentalis* L.). The segregation of characters in populations of seedlings derived from open pollination of London planes is evidence of this hybrid origin. Whether the tree originated at the Oxford Botanic Garden about 1670 (ref. 1) or developed earlier may never be known. Regardless of its origin, the London plane has proved extremely valuable as a tree that will endure the difficult environments of modern cities.

Both the common and scientific names of the London plane refer to an assemblage of trees that are generally intermediate between the two putative parents. It is doubtful whether any living, mature tree can be verified today as a true first generation hybrid. The variability among London planes is especially notable in the eastern United States, where trees of seedling origin have been planted along city streets. In addition to variation in morphology, the London planes in America exhibit a wide range of susceptibility to damage by sycamore anthracnose caused by the fungus *Gnomonia platani* Kleb.

There have been no previous reports of attempts at the controlled repetition of the cross, which I have now accomplished. In the spring of 1968, I made reciprocal crosses between trees of oriental and American planes growing at the US National Arboretum. This hybridization was part of an extensive breeding programme designed to develop better trees for city planting. The oriental planes were of authentic Turkish origin and were fruiting heavily at 14 yr old. The American planes were mature, native trees growing in the Arboretum.

Seed from these crosses was collected in December 1968, and kept at 5° C. Seeds were sown in flats in the greenhouse on April 28, 1969. Seedlings from hybrid and non-hybrid seedlots were handled alike during all cultural treatments. No fertilizer was applied to any of the plants while they were in the flats or pots throughout the growing season. Final heights were measured on October 22, 1969.

Unusual vigour was apparent in the hybrids even in the cotyledon stage. Cotyledons of hybrid seedlings were longer and broader than non-hybrids from the same mother tree. Average heights of fifty comparable 1 yr old seedlings per seedlot were for *occidentalis*, 14·8 cm; for *occidentalis* × *orientalis*, 26·3 cm; for *orientalis* × *occidentalis*, 29·1 cm; and for *orientalis*, 13·8 cm.

Height differences between the reciprocal hybrid populations were not significant by the *t* test, but the average height of the hybrids was nearly twice that of the parent species. Future measurements on a statistically designed field planting will determine whether this juvenile superiority of the hybrids is maintained in later life.

Transition Probabilities for a Forest

THE vegetation on a tract changes as a field or felled forest becomes a forest again, and a quantitative statement of the changes is needed for comparing one period of changes with another and for logical extrapolation to the equilibrium or steady state. Enumeration of the stems in four mixed hardwood forests during 40 yr has enabled us to test "transition probabilities" as a means of stating, analysing and making use of the observed changes.

If parts of a tract of land are dominated by one of several classes or states of vegetation, the changes from one state to another during a given interval, such as a decade, can be described by transition probabilities. A matrix of the transition frequencies for all states is a convenient summary of the changes. If the transitions do not depend on how the forest reached its present state but only on the present state, and if the frequencies are constant from decade to decade, the matrix is powerful as well as convenient. It is a stationary Markov chain[1], which has two useful properties.

First, the probabilities for an interval of several decades can be calculated by multiplying the matrix by itself. The second useful property involves calculating the steady state.

These properties are obviously desirable, and the only problem is whether the changes in a forest behave as a stationary Markov chain. Observations on a sufficient number of plots during a sufficiently long time to test the behaviour are rare, but fortunately we are heirs to an enumeration of all stems larger than 12 mm diameter, breast high, in about 5 hectares of mixed hardwoods in four central Connecticut forests. The first enumeration was made in 1927 when the trees were mostly 25 to 40 yr old[2]. It was repeated 10, 30 (ref. 3) and 40 (ref. 4) yr later. The enumerations have included 30,000 stems, but the population has decreased to half its original size. When the transects of the surveys are divided into 0·01 hectare tracts 20 m long and 5 m wide, and disturbed, dry and wet tracts are discarded, 327 fairly uniform plots remain for testing the behaviour of transition probabilities.

Sets of states can be conceived and the plots classified accordingly, but those that are easily understood and that produce constant probabilities independent of preceding states are most useful. Several classifications have been made and will be fully described elsewhere[4]. For this brief communication, however, the tracts were classified as maple, oak, birch, other major species or minor species according to which of the five classes had the most stems on the tract.

The stationary nature of the transitions among these classes in the forest is seen by comparing probabilities from period to period, but their Markovian nature is less easily demonstrated. The customary test for this requires that the classes be subdivided according to their antecedents and then observing whether the antecedents affect the transitions. In our case of five classes, subdivision would create twenty-five classes, and our 327 plots are too few to permit this treatment. Therefore another course has been taken.

Table 1. TRANSITION PROBABILITIES

	1927				
	Maple	Oak	Birch	Other	Minor
Observed 1937					
Maple	82	16	13	7	7
Oak	7	72	2	3	7
Birch	2	8	83	7	7
Other	0	0	2	69	7
Minor	9	4	0	14	72
Anticipated, 40 yr					
Maple	53	35	32	22	23
Oak	16	33	8	11	15
Birch	11	19	50	18	18
Other	2	2	4	26	11
Minor	18	11	6	23	33
Observed 1967					
Maple	62	32	22	45	20
Oak	0	15	0	0	4
Birch	16	23	54	10	21
Other	2	7	2	17	5
Minor	20	33	22	28	50

These transition probabilities are those observed in 1927–1937 (upper matrix); those for 40 yr obtained by multiplying the 1927–1937 matrix of probabilities by itself three times (middle matrix), and those observed in 1927–1967 (lower matrix).

The two properties of the stationary Markov chain which we described earlier were used; they produce much the same answers regardless of the decade of transitions used to obtain the probabilities. This has been taken as evidence of the stationary Markovian nature of the transitions in the forest. In the first demonstration (middle of Table 1) the transition probabilities for 40 yr are calculated by multiplying the matrix for the first decade (top of Table 1) by itself three times. These 40 yr probabilities are compared with the probabilities actually observed between 1927 and 1967. The principal difference between the transitions anticipated by multiplying the 1927–1937 matrix and the transitions observed concerns oak, which has persisted less than anticipated. On the other hand, several important features were anticipated. The persistence of maple, birch and minor; the transitions from oak to maple and birch; the transitions from birch to maple; and the transitions from other and minor to maple and birch could have been rather well predicted in 1937 by manipulating the matrix of probabilities for the first decade, as is done in the middle of Table 1.

Although the plots were not numerous enough to divide into twenty-five classes, they were divided into older and younger forests. They were also divided into moister and drier groups. The probabilities were reassuringly similar in different groups.

Table 2. PERCENTAGES OF FOREST PLOTS IN FIVE CLASSES AT STEADY STATE ANTICIPATED FROM TRANSITIONS OBSERVED IN TWO DECADES

Observations	Maple	Oak	Birch	Other	Minor
1927–1937	39	17	22	5	17
1957–1967	45	1	32	6	17

The final comparison is between the steady states anticipated from the transitions of the first and last decades. If the changes in the forest were an ideal stationary Markov chain, the two steady states would be the same. Whether the transitions of the thickets of 1927–37 or forests of 1957–1967 were extrapolated, the prediction was about the same: many plots of maple or birch, some minor and few oak or other (Table 2). The last decade of drought and defoliation did not change the direction of trends evident in the first decade. Thus the foresight of our predecessors who established the plots has permitted a demonstration that some transition probabilities for the forest can be treated as if they came from a stationary Markov chain, providing both an orderly way of comparing forest changes during periods of different length and of extrapolating into the future.

Possible Side Effects of Fungicides on Banana and Coffee Diseases

Experience suggests that excessive application of fungicidal sprays to crops has not had as many undesirable biological side effects as the excessive application of insecticides. Nor has there been much evidence, at least at the level of field application, of acquired resistance to fungicides[1].

There are various ways in which fungicide sprays may have an effect other than that intended, and in this respect recent publications on the non-parasitic microflora of leaves are interesting. Hislop and Cox[2], for example, discussed the implication of fungicide usage in relation to the balance of saprophytic and parasitic microorganisms of the phylloplane. And Furtado[3] emphasized that copper sprays bring about an increase in the population of virulent *Colletotrichum coffeanum* Noack in coffee bark. He quoted how coffee berry disease increased in Kenya as a result of copper spraying. Wallis and I[4] produced experimental evidence for this in 1967.

This apparent favouring of a virulent pathogen at the expense of a related saprophytic or less virulent form is a most interesting fungicidal side effect. The recent replacement of *Mycosphaerella musicola* Leach, the cause of Sigatoka disease of bananas, by *Mycosphaerella* sp., the cause of the much more serious black leaf streak disease, in Fiji and other Pacific territories could be viewed in this light. Details of this disease and its geographic distribution and spread have been described several times[5–8]. The black leaf streak fungus produces conidiophores sparsely and ascospores abundantly, in contrast to *M. musicola* which produces dense fascicles of conidiophores and relatively few ascospores. When he first observed this disease Rhodes[9] noted it on plantings where Sigatoka disease had previously been controlled effectively by oil spraying, which was not controlling the new disease satisfactorily. Stover and Dickson[10] noted that one of the effects of oil on *M. musicola* was to reduce the number of sporodochia and thus the number of conidiophores. It is conceivable that oil favours a form which already has the habit of sparse conidiophore production and relies chiefly on ascospore infection.

It can be argued that black leaf streak disease has so far not been reported in the principal banana producing countries where oil spraying is common. But coffee berry disease is not present in the principal coffee producing countries although *Colletotrichum coffeanum* is ubiquitous. Only in parts of Africa has there been replacement by a virulent strain. The mechanism by which these two virulent fungi have become prevalent is not known, and no similarity is now suggested. But the situation provides a warning that we should perhaps examine the effects of fungicide as carefully as those of other chemicals used for plant protection.

Hemiparasitic Flowering Plants: Phenotypic Canalization by Hosts

The idea of combining the desired qualities of two distinct genotypes is old and universally appreciated. The genetic information can be brought together in two ways: within the same zygote through hybridization; or, for example, in higher plants, by grafting the stem of a superior fruit onto a particularly hardy root system. It is increasingly clear that the phenomenon of grafting (like hybridization) is a common natural process in which the root systems (and stems) of genetically distinct individuals become functionally interconnected.

Such interconnexions are formed naturally in at least three ways: by mycorrhizal fungi[1,2], by natural root grafting among forest trees[3] and through the haustorial connexions of holoparasitic and hemiparasitic vascular plants (see, for example, ref. 4). Although the mechanisms of coupling and transfer differ markedly in these bridge-forming plants, they have in common the capacity to share the biochemical products of other genetically distinct individuals.

The hemiparasitic flowering plants that live in annual grasslands are of special interest because each year they come into random contact with a wide range of potential

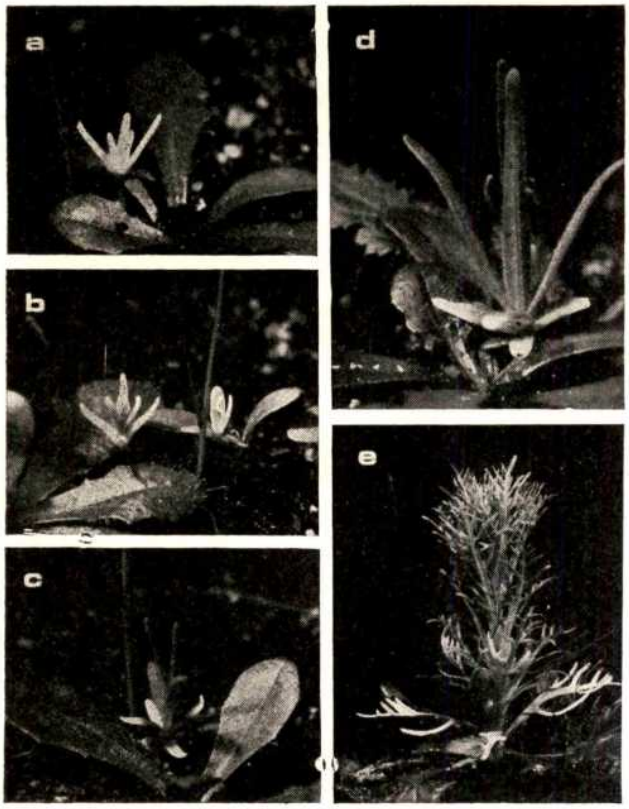

Fig. 1. *a–d*, Five week old albino *Orthocarpus* seedlings with host plants, *Hypochoeris glabra* and *Festuca myuros*. *a*, 1 cm seedling with 3 pairs of white leaves; *b*, seedling on left (1 cm) shows third pair of leaves beginning to turn green; *c*, 1·5 cm, *d*, 2·2 cm, initiation of rapid heterotrophic growth following production of green leaves. *e*, Eleven week old individual (12 cm) showing initial white leaves plus temporary chlorosis of new leaves as a result of low light intensity.

host species. Annual hemiparasites characteristically form haustorial connexions (root grafts) with most of the plants that surround them, including members of their own population. Single individuals may form root grafts with two or three different host species at the same time, and there may be as many as fifty potential host species available to the population as a whole[5].

Individuals of many hemiparasitic species are also capable of independent autotrophic growth. Populations of the annual grassland hemiparasite *Orthocarpus purpurascens* (Scrophulariaceae) contain a full range of autotrophic abilities, from individuals that can grow and reproduce without a host, to a variable number of plants that must have a host to mature and reproduce. When individuals are provided with host plants, mortality is often decreased and reproductive potential is usually markedly increased[6].

Because individuals with host plants survive better, normally non-viable individuals may be chemically buffered or canalized. Studies on the translocation of water, minerals, carbohydrates[7–11] and amino-acids[12] show that many, if not most, materials travelling in the host vascular system are received by grafted hemiparasites. To demonstrate the buffering capacity of host plants, one must be able to identify a lethal or semilethal phenotype at an early stage in development, before it is associated with the host plant. I now report an experiment with albino *Orthocarpus* which conclusively demonstrates deficiency correction through physiological buffering by host plants.

The albino seedlings were naturally produced after two generations of inbreeding between genetically self-incompatible *O. purpurascens* siblings. One progeny sample yielded about 10 per cent achlorophyllous seedlings; the remaining 90 per cent were entirely normal. At first, all seedlings had green cotyledons and the albino seedlings could not be identified until the first or second pair of true leaves emerged, about 10–14 days after germination. At the first sign of chlorosis, one day old host seedlings (*Hypochoeris glabra*, *Erodium botrys* and *Festuca myuros*) were introduced in various combinations around some of the albino seedlings and all other normal *Orthocarpus* seedlings removed. From a total of seventy albino seedlings, forty received host plants, ten were left surrounded by varying numbers of normal *O. purpurascens* seedlings and twenty were grown as single isolated individuals. The pots were randomized and placed in a controlled environment chamber with a 12 h photoperiod and diurnal and nocturnal temperatures of 21° and 11° C respectively. They were watered daily with deionized water and given liquid fertilizer every two weeks.

All thirty albino seedlings grown singly or with normal *Orthocarpus* siblings remained white and eventually died. The initiation of chlorosis varied with each individual, but two patterns were apparent: either the first pairs of true leaves were white as they emerged, or they were green or yellow and later turned white. All seedlings showing any signs of chlorosis continued to lighten until they were white, and thereafter produced only white leaves. Most of these individuals died within the first 6–8 weeks, but a few produced up to six pairs of very small white leaves and maintained themselves for up to 12 weeks.

In marked contrast to the minus-host treatment, ten of the forty albinos supplied with host plants began to turn green and grow rapidly during 12 weeks after the introduction of the three host species (Fig. 1). In general,

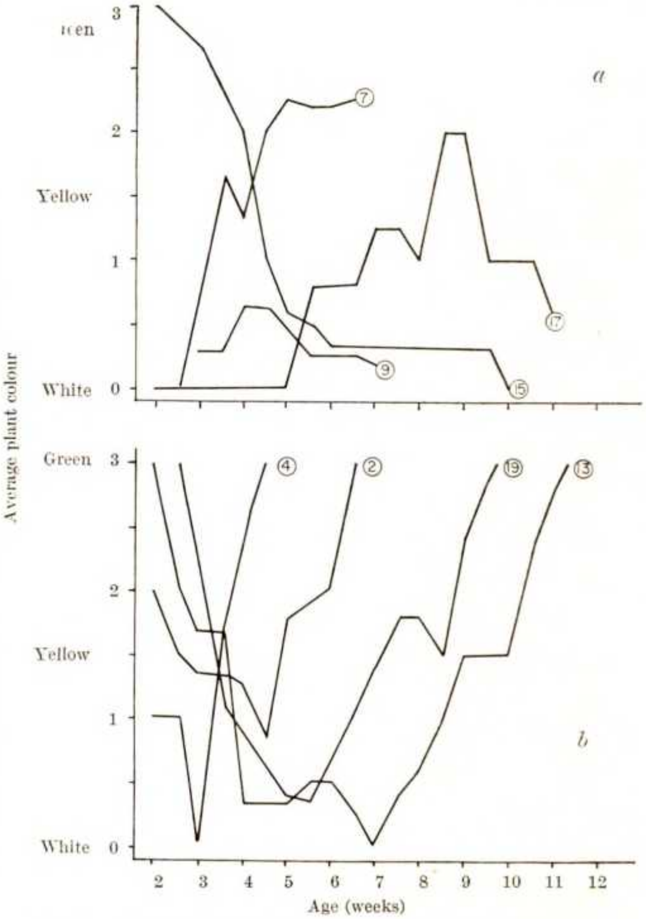

Fig. 2. *a*, *b*, Fluctuations in average chlorophyll content of 8 albino *Orthocarpus* seedlings grown with host plants. Leaf pairs were assigned values of 0 (white), 1 (light yellow), 2 (light green) or 3 (green), and averaged for each plant. Numbers in circles identify the experimental plants (see text).

once an albino seedling began to produce green leaves it also began to grow at the rapid rate characteristic of normally grafted *Orthocarpus* plants. The response of the albino seedlings to these host plants varied both temporally and with respect to colour, growth and survival (Fig. 2).

Seedlings that first produced a pair of white leaves (numbers 7, 9, 17, Fig. 2*a*) showed variable greening responses to their hosts but finally died. Plant number 15 (in Fig. 2*a*) exemplifies the many individuals that did not respond to their host plants, either through inadequate haustoria formation or because the host plants could not provide what the hemiparasitic individual lacked.

Seedlings that first produced green or yellow leaves had the highest incidence of survival (Fig. 2*b*). The short photosynthetic period during early seedling development may thus have increased the energy available for haustoria formation. But the different degrees of chlorosis first shown by the total seedling sample undoubtedly reflect a range of genetic differences. It is more likely that successful deficiency correction was possible only in those individuals with the least complex blocks in chlorophyll synthesis.

Five of the ten grafted seedlings survived and flowered normally. All individuals were fertile, but all sibling crosses failed, evidently because each individual was homozygous for identical incompatibility alleles. Reciprocal crosses between the albino individuals and normal green population members produced abundant seed.

This experiment provides an extreme but recognizable example of the kind of random chemical buffering that necessarily results from interconnexions between genetically distinct individuals. Viewed positively, developmental buffering by a wide range of host plants may be an important mechanism that occasionally canalizes genetically sub-optimal recombinants and mutants towards an optimal phenotype. A negative result of biochemical buffering is the probable accumulation of genes deleterious to autotrophism, leading to increased dependence on heterotrophic nutrition. In *Orthocarpus* populations, such relaxation of selection for autotrophism by chemical buffering is clearly counterbalanced by continual selection for autotrophism (1) in the seedling stage before host contact, (2) after haustoria formation if the host contribution is unsuitable, and (3) when host plants are not available.

Gliding in a Blue–Green Alga: a Possible Mechanism

GLIDING motility has been studied for many years with limited success[1-3]. The gliding movements displayed by several species of blue-green algae and bacteria have not as yet been satisfactorily explained. Earlier observations of gross behaviour and morphology have suggested several mechanisms, but we believe that none of the previous explanations encompass all of the motility characteristics observed in the blue-green alga, *Oscillatoria princeps* Vaucher (Fig. 1).

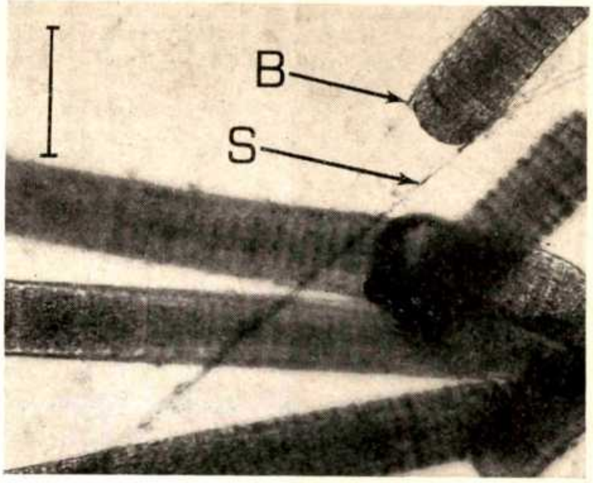

Fig. 1. Gliding trichomes of *O. princeps* are pictured using bright-field illumination. The sheath (S) is being shed by one trichome. A burr (B) of a broken cell is visible. The marker indicates 50 μm.

Our observations suggest that gliding motility is the result of unidirectional travelling waves on the cell surface acting against a solid substrate or a closely associated elastic sheath. These waves may be produced by a lateral deformation[4] of elements of a parallel array of fibrils (50 to 80 Å wide) which we have found to be continuous over the surface of the 30 μm wide trichome. This fibrillar array is wrapped around the trichome in a right-handed helix with a pitch of 60 degrees. The constant rotation of the trichome during gliding seems to be directly related to the dimensions of this helix.

Gliding motility, as noted by Jarosch[5], requires that the organism should be in contact with a solid substrate serving as a structural base on which the motility mechanism of the trichome acts. A thin elastic sheath is generally present and facilitates the purchase of the motility mechanism on the substrate by assuring a close contact on both sides. When contact is not established (as with trichomes suspended in liquid medium) the sheath material is displaced helically in bands over the surface of the trichome. Lacking contact with a solid substrate, the trichome itself does not move. The motility mechanism is thus acting between the cell wall and the sheath. Microscopic examination of the gliding trichomes confirms that the location of the shear zone is between the cell wall and the sheath envelope.

The cell wall of *O. princeps* is approximately 0·2 μm thick, and rigid. The burr of the cell wall left extended when a trichome is broken is not deformed by the elastic sheath casing (Fig. 1). Instead, the sheath is distorted by the burr as it is shed behind the moving trichome. The cell wall does not undergo any alterations in shape observable by light microscopy during the gliding process. Consequently, we have concluded that the motility system is probably located on the superficial portion of the cell wall.

Cells were fragmented by ultrasonic disintegration and the walls isolated by centrifugation. This process produced a large number of small fragments which were tightly coiled. They were mainly cylindrical wall casings which originally encompassed single cells. Ultrastructural examinination revealed that the fragments were turned inside-out. We interpret this to mean that there is a layer on the outer surface of the cell wall which is exerting an elastic force that causes the fragments to coil in this manner. The gross structure of the wall is, however, apparently unchanged by the isolation procedure. These observations also show that the surface of the cell wall may be the site of the motility system.

Ultrastructurally, the cell wall is composed mainly of a thick (2000 Å) structural layer immediately outside the plasma membrane. A 160 Å thick layer is present on the outer surface of the structural layer. The structural layer is penetrated by a series of 700 Å wide pores which terminate at the 160 Å layer. The cell wall is completed by a 90 Å thick membrane-like layer loosely wrapped around the other layers. The 160 Å layer and the outer "membrane" are continuous over the trichome surface and do not participate in cross-wall formation.

Surface sections of chemically fixed *O. princeps* were prepared as well as freeze-etch replicas of the trichome surface. A parallel array of 50 to 80 Å thick fibrils (Figs. 2 and 3) was found on the outer surface of the structural layer, apparently as part of the 160 Å layer. The fibrils seem to be continuous over the cross-wall junctions. If it is assumed that each fibril rapidly propagates waves of bending along its length, it may also be reasoned that the amplitude will be somewhat dampened (as compared with bacterial flagellar waves[7]) by the outer membrane-like layer or by the matrix in which the fibrils may be located. A solid substrate would be required for this type of mechanism to produce movement. As mentioned earlier, we have found this to be true.

The fibrillar array is aligned obliquely (Fig. 2) around the trichome, creating a helix with a pitch of about 60 degrees (that is, 30 degrees from the longitudinal axis). We have observed that gliding movements in *O. princeps* are always associated with a right-handed rotation relative to the direction of movement. It is likely that rotation is a necessary characteristic of gliding in this species. Attempts to impede rotations stop linear translation as well. The helix traced by any surface point on a gliding trichome also has a pitch of approximately 60 degrees. The same helical pattern is traced regardless of the velocity of forward movement. *O. princeps* glides at rates approaching 4 cm h^{-1} within 1 per cent agar. The velocity is greatly reduced by using higher concentrations of agar (up to 4 per cent) to harden the surrounding medium. Even here, the same pitch of the helical pattern is retained. This finding is consistent with the hypothesis that distortions of the fibrils actually constitute the propelling force. The reduced velocity in the more solid medium may result from an increase of slippage between the propelling waves and the substrate. Only a propulsion mechanism aligned helically in the manner of the fibrils would allow the perfectly matched helical movement patterns to be retained in these restrictive conditions. No other structural features (including pores) of *O. princeps* were found with a helical pattern.

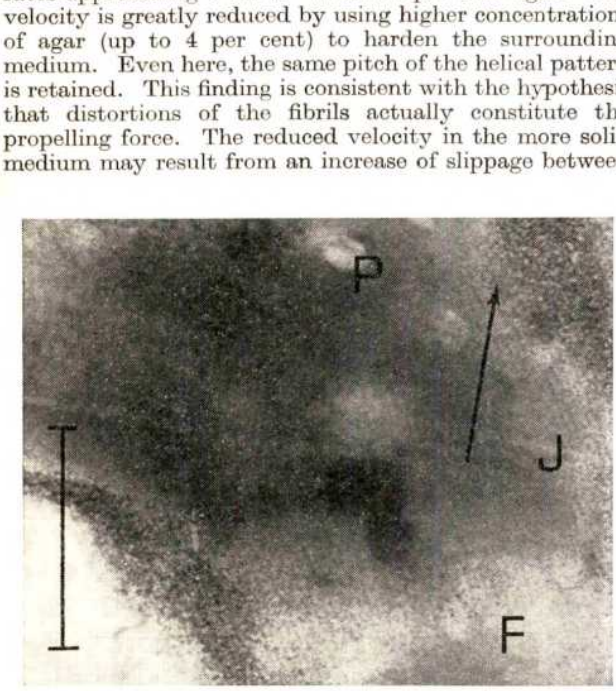

Fig. 2. Surface section of a chemically fixed trichome of *O. princeps*, revealing 50–80 Å wide fibrils (F) which are continuous across the cross-wall junction (J). A row of small junctional pores is seen on either side of the cross-wall. 700 Å wide pores are seen in the structural layer of the cell wall. The arrow indicates the longitudinal axis of the trichome. The marker indicates 500 nm. Image is reversed; Siemens Elmiskop 1A.

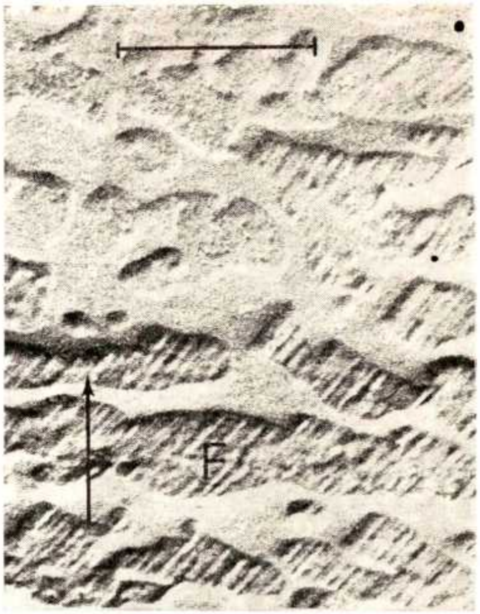

Fig. 3. Freeze-etch replica of a trichome surface revealing a parallel array of 50–80 Å wide fibrils (F). The arrow indicates the direction of platinum shadowing. The marker represents 500 nm.

We have observed that trichomes are able to reverse the direction of movement quickly with no apparent difference in speed[8]. The helix displayed by the surface point on a trichome which has reversed remains unchanged (that is, the direction in which the point travels to trace the helix is simply reversed).

It could be argued that the rotations observed during gliding movements are produced by the helical topography of the cell wall fibrils while some other mechanism such as mucilage extrusion[9] provides the force needed to move the trichome. No evidence has been produced from either light or electron microscopy to support this argument[10–12]. We believe that the undeformed fibrils themselves are too small to act as screw threads that simply guide the rotations. Further, because the fibrillar layer is covered by the outer "membrane" the process would be even less likely.

We prefer to believe that the fibrils actually propel the trichome. If the waves propagated by the fibrils are coordinated only to the extent that they are all travelling in the same direction, trichome movement with associated rotation should be the result when the sheath is attached to a solid substrate. Trichomes not against a solid substrate would displace the sheath in a helical fashion, as noted earlier. Reversals are explained if there is a rapid shift in trichome polarity with a subsequent change in the direction of wave propagation.

Isolation of a Virus infecting a Strain of *Mycoplasma laidlawii*

MYCOPLASMAS are a group of microorganisms which can grow on cell-free medium and which are characterized by pleomorphism, for they are bound by a triple layered unit membrane instead of a rigid cell wall. The smallest reproductive forms are about 100 to 150 nm in size. They are the smallest known free-living organisms comparable in size with the myxoviruses, to which they show some morphological resemblance. The largest mycoplasma cell can exceed 1,000 nm in size.

In view of the heterogeneity and wide host range of viruses, it seemed most unlikely that the biological characteristics of the mycoplasma cell would make the whole group resistant to infection with these agents. It was decided to investigate the susceptibility of mycoplasmas isolated from bovine nasal passages to virus attack. The bovine nasal passage was thought to be a favourable site for the multiplication and interaction of various mycoplasma species and strains. Virus screening was carried out by adding filtrates from other mycoplasma isolates to test mycoplasma. This report describes the isolation of a virus which infects a strain of *Mycoplasma laidlawii*.

Broth cultures of different isolates of mycoplasmas were prepared. These were not necessarily pure cultures, for many were recent isolates and not yet cloned. Aliquots of these were filtered through 'Millipore' 200 nm membranes. The filtrates were tested by adding a drop to solid medium plates seeded with each of the other mycoplasma cultures. The plates were examined after incubation for 24–48 h at 37° C, and showed a confluent lawn of host mycoplasmas; there was one exception where a distinct, clear zone of inhibition or lysis occurred at the site of application of the drop of filtrate. This zone, which covered the same area as the filtrate drop, was made up of a central partially clear area surrounded by a clear periphery with a partially clear halo on the outside.

The filtrate containing the inhibitory or lytic agent was completely inactivated on exposure to a temperature of 100° C (but not 60° C) for 30 min and ultraviolet light. It was sensitive to 5 per cent chloroform for 10 min but insensitive to 20 per cent ethylether at 4° C for 18 h. The agent, harvested from lawns of the host mycoplasma and diluted in phosphate buffered saline (PBS), *p*H 7·3, containing 10 per cent foetal calf serum, was serially filtrated through 'Millipore' membrane filters of decreasing pore size. It passed readily through filters of 10 nm pore size.

The agent in the initial filtrate was titrated in PBS in ten-fold dilutions and produced single isolated areas or plaques about 2–3 mm in diameter at high dilutions (titre of filtrate $2\cdot5\times10^9$ plaque forming units/ml.) on a lawn of the host mycoplasma. At lower dilutions these discrete areas coalesced to form one large zone (Fig. 1). Addition of a high dilution of the agent to broth cultures of growing mycoplasmas resulted in a 4–5 log increase in titre of the agent. Furthermore, a culture containing the agent in which the mycoplasmas had been inactivated by heating at 60° C for 30 min was subcultured on the host mycoplasma on solid medium 8 times. Each time a plaque was subinoculated into PBS and heated at 60° C for 30 min; the final subculture was equivalent to at least a 10^{-33} dilution of the original mycoplasma culture. There was no evidence of replication of the agent in the absence of actively growing cells of the specific mycoplasma. It therefore seems that this agent possesses properties consistent with those of a virus.

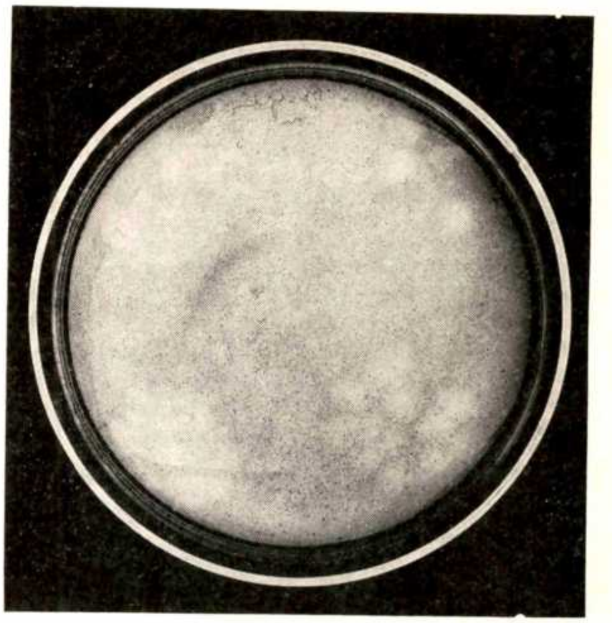

Fig. 1. Plaques formed by serial ten-fold dilutions of virus on *Mycoplasma laidlawii* strain BN1 culture plates. Stained neutral red.

The culture responsible for the host mycoplasma lawn was inoculated on to solid medium. It was purified by picking a single colony three times. The cloned culture (strain BN1) continued to receive the virus. This was apparent on a lawn of the cloned strain from the formation of plaques at the site of virus application. The cloned culture was able to grow at 22° C in serum-free medium and in the growth inhibition test[1] it was inhibited by antiserum to *M. laidlawii*.

This is the first report of the isolation of a virus which infects mycoplasmas. There has been a previous report[2], however, of small electron-dense bodies about 25–30 nm resembling intracellular bacteriophage in electron micrographs of the EAY strain of human mycoplasma, but, as far as is known, no virus was isolated then or subsequently. Evidence from the filtration experiments indicates that a viable unit of this virus can be exceedingly small.

I thank Mr I. Jebbett for the photograph and Miss Sara Wyld for technical assistance.

Entropy of Microbial Growth

A MAJOR problem in the thermodynamics of growth has been to account for the increase in information and structural entropy occurring during synthesis of new cellular material[1,2]. Thermodynamic measurements of the growth process in microorganisms now show that high fluxes of thermodynamic entropy occur, and are more than sufficient to account for the concurrent increase in information.

Table 1. THERMODYNAMIC DATA FOR ANAEROBIC GROWTH OF MICROORGANISMS WITH GLUCOSE AS ENERGY SOURCE

Organism	ATP Moles/ mole glucose	ΔH_c Observed kcalories/mole glucose	ΔF_c Calculated kcalories/mole glucose	Y_G Observed g cells/mole glucose	$T\Delta S_c$ kcalories/ mole	$\frac{\Delta H_c}{T}$ Calories/degree/ mole	ΔS_e Calories/ degree/ g cells	References
Zymomonas mobilis	1	−32	−56	8·4	24	106	25	7, 10
Streptococcus lactis	2	−26	−50	19·5	24	84	8	3, 10
Streptococcus faecalis	2	−31	−55	17	24	100	12	10, 24
Saccharomyces cereviseae	2	−31	−62	23	31	102	8	7, 10

Microcalorimetric studies with growing organisms show that while a large output of energy accompanies the process of catabolism, the amount of this energy incorporated into chemical bonds during growth is very small. The observed enthalpy change during growth agrees, within limits of experimental error, with the predicted value calculated from the difference between the heats of formation of the energy source and the degraded products of catabolism[3-7]. Generally, the enthalpy change from the coupled endergonic reactions of synthesis would be expected to subtract from ΔH_c, the enthalpy of catabolism[8], so that the enthalpy of growth, ΔH_s, is too small to be detected. Theoretical calculations confirm the experimental findings; in a rich complex medium containing the essential monomers for cellular synthesis, ΔH_s approaches zero[9]; that is, the energy incorporated into chemical bonds is not significant compared with the energy change from catabolism. Calculations of free energy change support the same view; the free energy of catabolism, ΔF_c, required to produce one mole of adenosine triphosphate (ATP) by the Embden–Meyerhof pathway of anaerobic glycolysis is at least -20 kcalories[10], but the coupled anabolic processes give rise to 10 g of cells with a free energy of synthesis, ΔF_s, of less than 100 calories/g[11] as calculated from the chemical composition of the cells. At least forty consistent determinations are available, showing that with many different microorganisms, about 10 g (dry weight) of new cellular material is synthesized for each mole of ATP produced by the catabolism of an energy source by a known metabolic pathway[12]. Calculations based on the known cost of energy for biosynthesis of cellular components indicate that up to ten times as much cellular material could be synthesized if all the ATP available from catabolic processes were used strictly for chemical syntheses[13,14]. These differences in energy between anabolic and catabolic processes cannot be attributed to a large requirement of energy for maintenance of the cells. Indirect estimations in growing cells suggest a small maintenance requirement[15], and, in non-growing cells, the use of the approximation that the entropy production of an organism can be determined by microcalorimetry[16] gives very rough estimates of the order of 10^{-3} calories/degree/g/h for cells of *Streptococcus faecalis* at 37° C (ref. 17), quite insignificant on the level of the growth process.

Thermodynamically, balanced exponential growth is a well defined steady state[18]. Each unit mass of growing cells may be considered as an open system which generates entropy internally at a constant rate, $\mathrm{d}\,S_i/\mathrm{d}t$, but, because a steady state exists, the internal entropy of the cells is maintained at a constant level by means of an equivalent outflow of entropy to the surroundings at a rate $\mathrm{d}\,S_e/\mathrm{d}t$ (ref. 19); each unit mass of existing cells is also synthesizing a new cellular material at a constant rate. Thus the entropically unfavourable process of growth becomes possible by coupling to the entropy production of catabolism[9,16].

In the microcalorimetric experiments conducted at constant temperature listed in Table 1, the outflow of entropy is due almost entirely to the degradation of the energy source. The thermodynamic entropy, ΔS_s, of the cellular material synthesized, calculated from ΔH_s and ΔF_s, is about 0·3 calories/degree/g. Independent calculations by Morowitz[9] give values of the same order; this is small compared with $\mathrm{d}\,S_i/\mathrm{d}t$. The outflow of entropy then has two major components, one ($T\Delta S$) due to catabolism and rejection of degraded products to the environment and the other $(\Delta H_c)/T$ due to the heat of the reaction; this heat is generated within the cells and then flows out to the environment[9].

Table 1 shows data reported for several organisms; these allow the calculation of the outflow of thermodynamic entropy during the production of 1 g of cells. The value of ΔS_e so calculated is greater than that necessary to accord with estimates of the amount of information contained in a bacterial cell. Such estimates, made by a variety of methods[20-22], range from 10^{11}–10^{13} bits per cell; ΔS_e can be compared with these by calculating the number of cells per g and applying the factor R ln 2 (ref. 20); all the organisms listed then give calculated values above 10^{13} bits per cell.

The data clearly demonstrate that only a small portion of the available energy is actually incorporated into cellular material; the major thermodynamic process is a large outflow of entropy from the growing cells. There is evidence for efficient energetic coupling during growth[23], so that the energy is not wasted. It follows that the major consumption of energy is that required for the correct placement of molecules within the cells into organized groups or structures.

Book Reviews

STRUGGLE FOR INITIATIVE

Atomic Shield 1947/52

(A History of the United States Atomic Energy Commission, Vol. 2.) Pp. xviii + 718. (Pennsylvania State University Press: University Park and London, November 1969.) $11.95.

THE possibility of war between the United States and the Soviet Union—real or imagined—was the background against which the atomic energy programme developed in the United States during the period covered by this volume. It seems inevitable therefore that, once the attempt to set up under the United Nations a system of control acceptable to both sides had failed, there was little chance of success for those who hoped that the newly formed Atomic Energy Commission would be able to concentrate on the peaceful uses of atomic energy, free from military pressures. The main theme of the book is the response of the commission to the continuous demands for increased weapons production.

In this context, the appointment of Lilienthal as the first chairman of the AEC was surely a mistake. He was an idealist who had achieved great success as chairman of the Tennessee Valley Authority for fifteen years—but the circumstances were quite different, and he seems always to be struggling against the tide. He was succeeded by Dean, who was more realistic and provides an interesting contrast in personality.

An account is given in considerable detail of the relations between the commissioners and the general manager (at first appointed by the President, later by the commissioners), and between the commission in Washington and their staff and contractors in the field. As in volume one, the authors present the detailed statements and attitudes of the principal characters, leaving the reader to form his own picture of each one, and to judge the correctness or otherwise of the decisions taken, political or administrative. Unfortunately, very few technical details can be given: most of them are still classified, as the authors explain in their preface. The interest must therefore chiefly lie in the interplay of personalities. One chapter deals with unclassified research in radiation biology, high-energy physics, and the transplutonium elements; but these and some references to radioisotopes and research reactors are not in the main theme.

The Atomic Energy Act, 1946, set up the commission and defined its powers, duties and organization in considerable detail. It also established a Congressional Joint Committee to make continuing studies of the commission's activities. Throughout the period they increased the scope of their interaction with the commission and the degree to which they took the initiative in directing and pressing the commission on matters of policy and sometimes of detail. This direct interference by a congressional committee in the affairs of a branch of the executive is unusual and makes most interesting reading.

The Atomic Energy Act also provided for a General Advisory Committee. Among its first members were people who had been long in atomic energy work, such as Conant, Fermi, Oppenheimer and Rabi. Though the committee had no executive powers it is very clear that the great scientific prestige of their members made them a powerful influence in determining the course to be followed by the commission.

With each successive demonstration of Soviet nuclear capability, the work of the commission increased to provide the new levels of materials and weapons requested by the military. On the naval side, Rickover's drive to develop nuclear powered submarines was already showing results.

Towards the end there is increasing emphasis on the activities of two men who are making special contributions: McMahon as the dedicated chairman of the JCAE, convinced that only the thermonuclear weapon can save the peace of the world; and Teller, resigning from Los Alamos in frustration at what he considered to be a totally inadequate scale of effort on the thermonuclear project, and getting support from McMahon and from Lawrence for setting up a new laboratory at Livermore.

The chapters on British proposals for re-establishing an effective interchange of information are interesting, but the wording of the Atomic Energy Act would have made it very difficult even without the strong opposition that existed in many places, including the commission itself. It seemed that on each occasion when a formula had been found which promised some relaxation, there would be some incident that confirmed the views of those who held that it would be against US interests.

J. F. JACKSON

THE BERNOULLI SAGA

Die Werke von Jakob Bernoulli

Herausgegeben von der Naturforschenden Gesellschaft in Basel. Band 1. Pp. xii + 541. (Birkhäuser Verlag: Basel, 1969.) Sfr 76.

Hydrodynamics

By Daniel Bernoulli. And Hydraulics. By Johann Bernoulli. Translated from the Latin by Thomas Carmody and Helmut Kobus. Pp. xv + 456. (Dover: New York; Constable: London, November 1969.) 142*s* 6*d*; $15.

THE history of the Bernoulli family is well known; starting with a burst of genius in the two brothers John and James, it included two of nearly equal talent in the next generation (Nicolas and Daniel) and continued a tradition of excellence down to this day. To these first two generations goes much of the credit for the creation of the modern science of rational mechanics. The story has been well told by Truesdell: taking physical ideas from Newton and Huygens, and mathematical tools from Leibniz, they achieved effective methods for the solution of many deep problems. Their student and successor, Euler, then brought the science near to the classic form finally achieved in the nineteenth century. It should not be thought that theirs was a happy family endeavour; John and James quarrelled over priority, and late in life John tried to steal credit for achievements in hydrodynamics from his son, Daniel.

These two volumes which have recently appeared provide material on very different periods in the history of the family. The first volume of James Bernoulli's *Works* is devoted to "Juvenalia": material dating from the period before his discovery of Newton's mechanics and Leibniz's calculus. The editor's modest title for this work may be misleading: Bernoulli was long past his schooldays by this time, and the pieces (most of them published) show full mastery of the mathematics and natural philosophy (speculative and experimental) of his time. In metaphysics and logic, his work shows a mixture of the remnants of a scholastic type of philosophy (which flourished in German universities through the seventeenth century, following its renovation in the sixteenth) and Cartesianism. The shock of the complementary achievements of Newton and Leibniz must have been great. We know that by 1690 Huygens was too old to adjust to them, but the young Bernoullis rose to the challenge and developed the elements of a new synthesis.

The second volume will be of greater interest to a reader trained in mathematical physics. For here in English translation are two classics, in which the science of hydrodynamics was founded. Putting the two works together has greatly enhanced their value; for in this pair, there is a scientific and a personal drama. Daniel Bernoulli's book (of 1738) explores a variety of problems of practical and theoretical interest, including the motion of waters inside and on leaving vessels, hydraulic machines, and "elastic fluids". His basic conceptual tool was not Newtonian mechanics, but what can be called the pendulum principle, derived from Galileo through Huygens. (The reader who wants to browse this work should first study the brief section at the beginning of chapter three where the fundamental ideas are developed; almost any subsequent argument can then be followed easily.) Application of this principle enabled him to make a first investigation on the problem of the pressure of a moving fluid on the walls of the pipe; and he did direct experiments to test his results, as was his practice.

Daniel's aged father John immediately attacked this last problem; and by improving its conception (and using Newtonian mechanics) he was able to derive its solution in the classic form of "Bernoulli's Theorem". On this special topic he produced a masterpiece; but, not content with the credit for improvement, he tried, by various devices, to arrogate full credit to himself. Euler was a friend of both father and son; and whether he avoided compromising himself in this nasty business is a question of historical interpretation. The preface by Hunter Rouse tells the story well; he could have pointed out that the first paragraph of Euler's letter to John, printed with the book, did give basic priority to Daniel.

In fact, the two books give a good sample of the distinctive styles of father and son: Daniel was a man of wide interests (he taught medicine at Basle !), concerned with experiment and with technical applications, but lacking the deep mastery of physical concept and mathematical technique that brought immortality to his father and uncle. In the translation, notation is slightly modernized but the words stay close to the original; this is fortunate, because a modernization of Daniel's mechanics would have made it unintelligible. It is a pleasure to see that Dover Books, who in the past have served the history of science so well by providing inexpensive editions of classics in translation, are back in the field, even if at a "library" price.

J. R. RAVETZ

COMPUTER ECONOMICS

The Economics of Computers

By William F. Sharpe. Pp. x + 571. (Columbia University Press: New York and London, October 1969.) \$10; 90*s*.

THIS is a report of a study made by the Rand Corporation. It is in two main sections: the first, of 180 pages, is on economic theory generally while the second deals specifically with the computer world and has chapters on the computer industry generally, on the marketing and pricing of computers and associated services, and on the costs and effectiveness of complete computer systems and of major components such as central processors and stores ("memories" here).

The first section gives a lot of useful background material which it is handy to have by one, but the real interest is in the second. The chapter on "The Computer Industry" gives a fascinating account of the history, development and present (meaning 1968) structure of this remarkable enterprise, whose growth from zero in 1950 to its present status of a truly major industry is one of the phenomena of our time.

The author emphasizes the importance of the part played by government in this development; on p. 186 he says "... it can plausibly be argued that without government (and particularly military) backing there might be no computer industry today". The whole book is concerned almost exclusively with the American scene and the author make no bones about it—IBM dominates, and has done since 1956, just as it dominated the punched card and tabulating machine market in the pre-computer era. The rest of the world gets two pages at the very end, in a section headed "Computers Abroad"—but, ironically enough, the author says (p. 204) that "perhaps the most analysed group of computer manufacturers is that in the United Kingdom". This chapter is chiefly a presentation of facts, as are those on sales and rental of computers, and also, though to a lesser extent, chapter twelve (the final chapter) on "Services, Markets and Costs".

The titles of two long chapters in the middle of the book hold promise of great interest—chapters nine and ten on "Cost and Effectiveness of Computer Systems" and of "Memory" respectively. Computers are expensive things to buy and to run—big systems are very expensive—and it is obviously very desirable to have some measure of cost-effectiveness to guide one's choice between rival manufacturers' offers. They are also very complicated things, so one can expect the problem of finding such a measure to be difficult. The main impact of these chapters is to show just how difficult it is. The author deals with all the types of performance measurements which are well known in the computing world; for example, simple criteria depending on the times for a very few basic operations, more complicated instruction-mixes, times for standard machine-code programs or "bench-mark" collections of programs in high-level languages and several less well known ones proposed by various individual investigators. Some of these latter seem rather odd, such as the formula on p. 313 which involves a number of constants and cook-factors whose values were determined, apparently, by a sort of public opinion poll (though among only forty-three "engineers, programmers and other knowledgeable people"). Many proposed methods involve weighting factors for various operating times, which again are very subjective. The author is quite honest about all this, and shows by quoting results of actual tests that different measures can give wildly inconsistent ratings of the relative performance of two systems. The main lesson to be learned is that one has to be very cautious in interpreting the results of any such tests. This is not altogether unknown.

The book is quite long—556 pages—and is packed with detailed factual information. Wherever possible the arguments are carried on quantitatively, so there is a fair amount of algebra but no very elaborate mathematics. It is well worth having as a stimulus to thought about the assessment of computer performance, for its surveys of the industry and for the very large number of references to relevant work, up to 1968, most of which would be very difficult for the unaided worker to track down.

J. HOWLETT

BUSINESS IS BUSINESS

Think

A Biography of the Watsons and IBM. By William Rodgers. Pp. 320 + 10 plates. (Weidenfeld and Nicolson: London, January 1970.) 50*s*.

How IBM with "the punched card that changed the world" is becoming the largest corporation on Earth is the subject of this new book by William Rodgers. Concentrating on the people rather than the computers, Mr Rodgers shows that these amazing machines are less fascinating than the managers who sell them, and his book has therefore apparently not gone down well with the company.

This book will be grist for many an amateur psychologist. What is to be made of Thomas J. Watson who turned

IBM into the world's largest non-union company and whose incredible presence loomed over IBM from three years after its founding until his death in 1956 ? From a beginning, peddling pianos and organs from the back of a wagon, Watson graduated by a tortuous route to become a salesman for the National Cash Register Company where he came under the influence of John Henry Patterson, the founder of "The Cash" as it was called. From Patterson, Watson learned how to work under a tartar who made a speciality of sales conferences where salesmen who missed their quota publicly confessed failure, as well as the ways and means of knocking out competition which later attracted attention in a lingering anti-trust case.

Under the threat of a prison sentence—a result of the anti-trust action—which simply died away in a welter of appeals, Watson left The Cash in 1914 to join an unpromising holding company called The Computer-Tabulating-Recording Company which Watson later rechristened International Business Machines, manufacturing as well as bookkeeping machines such equipment as scales and bacon slicers. Watson moved slowly at first, no doubt because deference had become deeply ingrained through his experiences with Patterson, but by 1924 he was visibly in charge and becoming a replica of Patterson. From then on he steered IBM up to the 1950s when his son Thomas J. Watson jun. took over.

IBM probably weathered the depression better than most as a result of government demands for improved bookkeeping that stimulated the sale of machines, just as the effects of the Marshall plan helped IBM in Europe after the Second World War, and during the depression Watson is said to have been the most highly paid citizen in the United States, a record which took some living down. He instituted a whole IBM ritual (Rodgers calls it worship) with THINK as the ubiquitous all-purpose symbol which had to appear on every executive's desk.

Watson also presided over IBM's big mistake—the failure to take on ENIAC, what might be called the first electronic computer, when it was handed to IBM on a plate by its builders, J. P. Eckert and J. W. Mauchley. IBM had been working on large electromechanical computers in cooperation with, among others, the astronomer Wallace Eckert (no relation of J. P. Eckert) who used IBM equipment to check the calculations in Brown's lunar tables, and Howard Aiken who was responsible for the electromechanical IBM Mark 1 machine at Harvard which made a sound "like a roomful of ladies knitting". Like many computers since, the Mark 1 was made obsolete almost as soon as it started work by ENIAC, which used valves. Discouraged, apparently by Watson, Eckert and Mauchley went to Remington-Rand where they produced the first commercial electronic computer, UNIVAC. Remington-Rand failed to press their advantage, however, and Rodgers quotes "snatched defeat from the jaws of victory".

IBM entered the computer industry proper in 1953 with the 701 machine and its 4,000 valves. The company has not been without its crises since. There was the failure of the STRETCH computer which left the way open to Control Data Corporation in the field of big machines. In the mid sixties there was the situation where taken together companies such as Honeywell, Control Data, Remington-Rand and Burroughs were ahead in computer technology, but not, as usual, in marketing. This stimulated the establishment of the IBM 360 series, announced in 1964, one of the first families of compatible computers.

Once again IBM is embroiled in anti-trust cases which could drag on until 1974, and Rodgers sees it as conceivable that the company could be broken up, although he is convinced that the pieces will continue to grow like the whole. Perhaps because company material was denied him, Rodgers's account becomes less complete as the time he describes approaches the present. Apart from the Eckert-Mauchley incident, for example, Rodgers gives few hints about why IBM was so slow in entering the electronic computer business. But Watson's background in selling built up in the years with The Cash and earlier developed in IBM the receptiveness to the wishes of customers, which was manifested in IBM's provision of software for computer users and the development of a powerful service organization. The company's performance in the military area, something less than might have been anticipated, encouraged the search for business markets which in the end are proving more lucrative. Rodgers's book, then, is not going to be a panacea for the companies eking out their market shares from the crumbs dropped by IBM, nor does it say how the world is going to live with IBM and its computers, but it is an extraordinary account of the people who fashioned the company.

EDWARD PHILLIPS

RUSSIAN PROBABILITY

Probability Theory

Basic Concepts, Limit Theorems, Random Processes. By Yu. V. Prohorov and Yu. A. Rozanov. Translated by K. Krickeberg and H. Urmitzer. (Die Grundlehren der mathematischen Wissenschaften in Einzeldarstellungen mit besonderer Berucksichtigung der Anwendungsgebiete, Band 157.) Pp. xi + 401. (Springer-Verlag: Berlin and New York, 1969.) 68 DM; $18.70.

THE Russian school of probabilists has, throughout this century, been in the forefront of advance both in the pure mathematical theory and in its application to practical problems. It is therefore particularly interesting to have available in English this standard text by two distinguished and influential authors. There are, of course, a number of texts available at this level (senior undergraduate and postgraduate) which cover roughly the same ground, and it is fascinating to compare both the content and the flavour of the different books.

Apart from such differences, the main point to remark is that the authors are to be taken at their word when they describe the book as "a survey of the most important results, methods and trends of modern probability theory". Almost all proofs are omitted, and it thus becomes possible to cover a remarkably wide field in some depth. Indeed, the book tempts one to wonder whether the insistence on detailed proof which informs most authors of advanced texts in pure mathematics is altogether a good thing.

As one would expect, there is a good deal about the basic measure-theoretic (and topological) structure underlying probabilistic problems, and random processes in particular, and a welcome account of the limit theorems for independent variables, both classical and more recent. The chapter on Markov processes is surprisingly earthy, and far in spirit from the work of Dynkin and his followers, but the interesting and detailed final chapter on stationary processes is more predictable. A number of topics usually absent from accounts of probability theory make at least brief appearances; information, coding, optimal control, for example.

Although this book is not likely to be widely used as a text, it will find a useful place as a work of reference on many bookshelves. The translation, though stilted, is readable, and the printing is excellent.

J. F. C. KINGMAN

MORE NMR

Nuclear Magnetic Resonance Spectroscopy

By Ruth M. Lynden-Bell and Robin K. Harris. (Studies in Modern Chemistry.) Pp. viii + 160. (Nelson: London, November 1969.) 70*s* boards; 35*s* paper.

THE justification for yet another book on the principles of nuclear magnetic resonance spectroscopy cannot but be a slender one. The authors believe that "there is a need for a short monograph dealing with the physico-chemical basis of the subject". This is an arguable point. Most undergraduates will not be able, with their overcrowded syllabus, to devote the time and effort to NMR that this book requires; and postgraduate students will want to go further than it can take them. The authors have been bred on NMR, and their grasp of the fundamentals clearly shows up in their style. The text is lucid and commendably up to date.

An attempt has been made, with some success, to present the physico-chemical basis of NMR spectroscopy without becoming too immersed in the mathematics. The direct consequences of the use of SI units are briefly summarized in an introduction.

The first chapter deals with basic principles and presents a standard treatment of the NMR phenomenon in both classical and quantum mechanical terms. A clear discussion of equivalence and some experimental aspects are included. Chapter two describes the quantum mechanics involved in spectrum analysis, including the composite particle method for equivalent nuclei. Chapter three covers the various factors which may affect the NMR parameters. The contributions to nuclear screening of electric dipoles, bond anisotropies, ring currents, solvent effects and similar factors are detailed along with the theories of spin coupling in a concise but clear fashion. In line with current practice, all discussion of shielding and de-shielding of nuclei is in terms of shifts in frequency rather than field.

The final chapter covers relaxation and related phenomena and certain aspects of double resonance. Problems are given at the end of each chapter, together with some of the answers. The book is attractively produced and looks remarkably free of errors. The only three that I have noticed are quite trivial.

The contents are familiar stuff; indeed, the authors do not pretend that they are anything else. But the book is attractively written, and for this reason worthy of study by those giving NMR courses to undergraduates and postgraduates. The paperback is a little expensive.

D. E. WEBSTER

RADIATION HAZARDS

Induced Radioactivity

By Marcel Barbier. Pp. xiv + 424. (North-Holland: Amsterdam, 1969.) 152*s*.

THE increasing number of nuclear reactors and high-energy particle accelerators in operation has caused the study and control of radiation hazards to assume a growing importance. A significant part of the radiation dangers associated with nuclear installations arises from the artificial radioactivity induced in materials exposed to the primary radiations present and, because the induced activity may persist for a considerable time after the primary flux has been turned off, it is particularly important to be able to estimate its intensity in advance. This book is a survey of induced radioactivity as a radiation hazard, with special emphasis on the problems of predicting radiation fluxes caused by activities induced by particle accelerators, as well as by reactors.

The subject is a complex one, for the radiation danger to be expected from a sample of irradiated material is a function of many variables in addition to the nuclear cross-sections involved. Dr Barbier has attempted to make a systematic treatment of the problem, and has put into an orderly and useful form a large amount of data from theoretical calculations and experimental measurements.

The work may be described roughly as a textbook on induced radioactivity, coupled with a reference handbook of nuclear data relevant to the subject. It begins with an elementary introduction to the physical phenomena involved, and there are general accounts of growth and decay of activity, absorption of radiations and biological effects. Parameters of use for practical calculations are introduced (such as the "danger parameter" which takes into account activation cross-sections in a material, self-absorption, and biological effectiveness of the radiations emitted). Separate chapters then deal in detail with activation involving spallation reactions and compound nucleus reactions; and activation by neutrons, by electrons and photons, and by heavy ions. Finally, activation in human tissues is discussed. Graphs and tables are provided for each topic, including, in many cases, results obtained by Barbier and his colleagues at CERN. Each chapter is followed by a number of numerical problems, with solutions given at the end of the book. This is an unusual feature in a book of this nature, but such problems can be useful for somebody approaching the subject for the first time.

There are a series of appendices containing reference data which will probably be as useful for those who have to make activation calculations as the text itself. As well as standard data, including a reprint of the "G.E. Chart of the Nuclides", there are special tables and graphs for use in calculations of activation by charged particles, neutrons and photons. There are some fifty graphs in this part of the book alone.

Altogether, this is a comprehensive book which brings data from many sources into a convenient form. It should form a very useful reference work for anybody engaged in assessing hazards of induced radioactivity around accelerators or reactors.

R. W. P. DREVER

SOLUTION BEHAVIOUR

Solute–Solvent Interactions

Edited by J. F. Coetzee and Calvin D. Ritchie. Pp. xiv + 653. (Dekker: New York and London, July 1969.) $29.50; 280*s*.

To bring together within one volume the whole spectrum of knowledge on solute–solvent interactions is an impossible task, and the editors are to be complimented in making a selection of topics covering several representative areas of the subject. Each of the eight chapters is written by an expert in the particular field and care has been taken to relate ideas between the various contributions wherever this is possible.

The first chapter, by J. W. Larson and L. G. Hepler, is concerned primarily with the thermodynamics of ionization of acids in aqueous solution. Extensive tables of thermodynamic data are included for both organic and inorganic materials. The second chaper, by R. G. Bates, is devoted to effects of the medium and *p*H in non-aqueous solvents. This is followed by a discussion of acidity functions by R. H. Boyd. The Hammett function is first considered, but the survey then broadens to acidity functions based on the use of tertiary aromatic amine indicators, amide indicators, azulenes and cyanocarbon anions. A brief description of experimental methods is included.

The fourth article, by C. D. Ritchie, deals with interactions in dipolar aprotic solvents. As comprehensive coverage of this topic is beyond the scope of a single chapter, four principal aspects have been presented—equilibrium acidities, proton transfer rates, nucleophilic substitutions and the dipolar complexing of non-electrolytes. It is possible that investigation of such fields by physical techniques may aid a better understanding of organic synthesis.

A contribution from H. Schneider concerns the selective solvation of ions in mixed solvents. The classical techniques of conductance and transference are first discussed and then follow more modern spectroscopic methods.

In chapter six, E. M. Arnett and D. R. McKelvey deal with the solvent isotope effect on solute behaviour. Almost all of the thermodynamic data refer to the H_2O/D_2O

system. The following contribution, by P. M. Laughton and R. E. Robertson, is closely related and considers the effect on equilibria and reactions. Once again the data refer to H_2O and D_2O.

J. F. Garst, in his chapter, deals with the variations in rate and equilibria of organo-alkali compounds in protic and aprotic solvents. The ethers are singled out for particular detail. The volume is concluded by a very brief appendix by the editors, listing the recommended methods of purifying selected solvents.

Taken overall, the book seems to have particular appeal to the specialist interested in the application of the methods of physical chemistry to the problem of solution behaviour. Perhaps its specialist interest is reflected in its high price. J. A. SALTHOUSE

FLUORIDE POISONING

Toxic Properties of Inorganic Fluorine Compounds

By R. Y. Eagers. Pp. x + 152. (Elsevier: Amsterdam, London and New York, 1969.) 55*s*.

SINCE the publication of Largent's excellent work (*Fluorosis*, Ohio State University Press, 1961) on the metabolism and toxicology of inorganic fluorine compounds, much information has been published on the subject which, with earlier works, is condensed in the 118 pages of this monograph. This book is best where it is more condensed, as in the sections on effects on insects, plants and bacteria or when discussing endemic fluoride poisoning in humans and in animals. The text is vague, repetitive and disorganized when the author tries to express his own ideas as in the major part of the chapter on human intoxications. His definitions are often inaccurate or ambiguous. Thus on page 8, the words suggest that acute fluoride poisoning from inhalation is not an industrial hazard although it may result from atmospheric pollution. In the chapter on acute poisoning (page 25) it is stated that "Acute fluoride poisoning by inhalation is essentially an industrial hazard", yet he goes on to say, "Normally, fluoride poisoning by inhalation may be described as chronic rather than acute. . . ". Sometimes even the subtitles are misleading, as under the heading of "Absorbed Fluorides". Here the author discusses the effect of exposure by the dermal route, but, hypnotized by the drive to marry title and material, he opens this section with the surprising statement that "Acute fluoride poisoning by absorption usually implies that the fluoride is absorbed through the skin as a result of local contact", but immediately proceeds, "Strictly speaking, all acute fluoride poisoning is the result of absorption", and then explains that ingested fluoride is absorbed through the gastrointestinal tract and inhaled fluoride is absorbed through the respiratory tract.

This disorganized compilation includes much repetition and the separation of logically inseparable parts. Thus fluorides are characterized and their threshold limits are given on pages 4–7 and again on pages 76–80. Acute, subacute and chronic animal experiments are reviewed in the second chapter entitled "Effects on Animals" under the subtitle of "Acute Poisoning" and in the third chapter on "Other Effects" under the subtitle of "Physiological Effects". This latter section is inserted between "Effects on Plants" and "Effects on Bacteria". The characterization of some of the fluoride compounds is in many cases too imprecise, and because preventive measures are proposed for some but not the other compounds, the reader might believe that these latter may be handled without risk.

The monograph may serve a useful purpose as a collection of 730 references, but the reader is advised to use only those pages and paragraphs in which the density of reference numbers is above a certain threshold limit. L. MAGOS

FUNGAL TOXIN

Aflatoxin

Scientific Background, Control and Implications. Edited by Leo A. Goldblatt. (Food Science and Technology : a Series of Monographs.) Pp. xii + 472. (Academic Press: New York and London, October 1969.) 201*s*.

ALTHOUGH the effects of mycotoxins have been observed for many years, comparatively little was known about their cause. From 1960 onwards this state of affairs has been dramatically altered as a result of the large-scale outbreak of a mycotoxicosis among turkey poults, which was known as "Turkey X" disease. The cause of "Turkey X" disease was eventually traced to the presence of a group of mycotoxins, in a groundnut-based feed contaminated with a strain of the mould *Aspergillus flavus*. The group name given to these mycotoxins was "aflatoxin". In addition to their toxic properties the aflatoxins were shown to be highly carcinogenic to many species. Since that time many research workers have expended a tremendous amount of effort in solving the problems associated with these compounds, and the net result of this work, which comprised more than five hundred papers by 1968, has been presented in this book under the editorship of Dr L. A. Goldblatt.

It is understandable that in attempting to produce a work on such a diversified subject, there must be a number of authors involved, and it is unavoidable that in a number of the contributions there is a tendency for repetition of the information.

The content of the book reflects the wide range of disciplines involved in solving the aflatoxin problem. The topics covered are dealt with in a total of fifteen chapters and they include the chemistry, production, assay, effects, metabolism and detoxification of the aflatoxins. The first chapter is a general introduction by the editor, and the subsequent ones contain a large amount of evidence and information, which in many cases is presented in a very useful tabular form. Another contribution is a list of precautionary measures to be taken when handling aflatoxins. These precautions should be made mandatory for all persons engaged in aflatoxin work, for it now seems extremely likely that aflatoxins are carcinogenic for man. In this latter connexion it is reassuring to read that a great deal of thought has been given to the protection of consumers from the aflatoxins. With this point in mind an appendix is included which contains a voluntary code of practice, currently in operation in the United States, for marketing and distribution of groundnuts.

Although the book is ostensibly about the aflatoxins, there are several chapters which contain information concerning fungal spoilage of food, and mycotoxins in general. These generalizations help to place the aflatoxin problem in perspective, for, after all, the aflatoxins constitute only a few of the known mycotoxins. In fact, it is claimed that some of these other mycotoxins have at least equal importance to that of the aflatoxins themselves.

There is no doubt that, because of the authoritative and intensive manner in which this book has been compiled, it will remain a standard text on the subject of aflatoxins for many years to come. M. F. DUTTON

YEAST BIOLOGY

The Yeasts

Vol. 1: Biology of Yeasts. Edited by Anthony H. Rose and J. S. Harrison. Pp. xiii + 508. (Academic Press: London and New York, November 1969.) 140*s*; $19.50.

YEASTS are constantly impinging on our daily life and they do so probably to a greater degree than other microorganisms. Not only are these organisms the exploited industrial slaves of baking, brewing, wine and cider making and distilling, but they are also sources of human and animal food. To the biochemist, yeast is an extremely adaptable organism, eminently convenient to use in a wide range of studies such as in current intensive investigations on mitochondrial structure and function. Eleven years have elapsed since Academic Press printed as a single volume *The Chemistry and Biology of Yeasts*, edited by Dr A. H. Cook, and it is perhaps a reflexion of the rapid flow of yeast research that the substantial volume under review is the first of three devoted to yeasts.

The contributions within volume one of *The Yeasts* fall broadly into four fields of study: (1) yeast taxonomy and systematics; (2) yeast ecology; (3) yeast life-cycles and genetics; and (4) yeast cytology. It is interesting that in the introduction the editors refer to the difficulty in providing a satisfactory definition for yeasts in spite of the fact that only about 350 species grouped into 39 genera are involved. A contribution by N. J. W. Kreger van Rij on "Taxonomy and Systematics of Yeast" is generously illustrated by photomicrographs and is comprehensive except for the traditional omission of black yeasts such as *Aureobasidium* (*Pullularia*) *pullulans*. (There is, incidentally, considerable reference to this yeast in chapter five but no entry in the index.) "Distribution of Yeasts in Nature" is splendidly surveyed by L. do Carmo-Sousa—she largely reviews data published after 1956 and up to 1967. The chapter by J. C. Gentles and C. J. La Touche on "Yeasts as Human and Animal Pathogens" has a title which seems to disclaim that man is an animal, but the distinction drawn is presumably one of convenience. Following the discovery in 1839 that thrush disease is caused by yeast, many examples of candiasis and other yeast infections have been described. The chapter describes them in detail along with serological and therapeutic aspects. To complete ecological considerations of yeasts, F. T. Last and D. Price provide a chapter on "Yeasts associated with Living Plants and their Environs" for which they have the unenviable task of separating the effects of yeasts from those of other fungi on plants. The authors attempt to answer such questions as where are fruit-inhabiting yeasts to be found in the winter, and do certain yeasts fix nitrogen in the soil?

The contribution on "Yeast Cytology" by P. Matile, H. Moor and C. F. Robinow is a substantial and valuable account of the structure and function of the various parts of the yeast cell. In particular, the extended consideration of Lindegren's various hypotheses on nuclear structure is particularly welcome. Like the chapter on "Yeast Genetics" by R. K. Mortimer and D. C. Hawthorne, that on "Yeast Cytology" brings together a great deal of research from a wide range of journals and provides an authoritative summary of present knowledge. "Sporulation and Hybridization of Yeasts" by R. R. Fowell is a comprehensive account of the methods used in yeast genetical work and fits in admirably with a second short chapter on "Life Cycles in Yeast" by the same author and the chapter on "Yeast Genetics" already mentioned.

The editors and authors are to be congratulated on this first volume. It is a valuable and well presented handbook for those carrying out yeast research, while biochemical and microbiological libraries will require it as a reference volume.

J. S. Hough

Obituaries

Dr A. Tindell Hopwood

Arthur Tindell Hopwood, a member of the scientific staff of the British Museum (Natural History) for thirty-three years, died in London on October 23, 1969.

Born at Macclesfield on July 15, 1897, Hopwood received his education at Manchester Grammar School and saw service during the 1914–18 war as a navigation officer in the Royal Naval Air Service. Afterwards he entered the University of Manchester and took the special honours course in geology and zoology devised by Professors O. T. Jones and S. J. Hickson. A born naturalist, Hopwood's enthusiasm for natural history—from conchology to human morphology—together with his attractive personality rendered him *persona grata* in the university departments and in the Manchester Museum, and he made full use of the facilities he was offered. His promise secured him the exceptional privilege of admission to the dissecting room to study limb musculature and osteology. This experience impressed upon him the dependence of form on function. That every bone is but the reflexion of its natural environment was a lesson well learnt, one which was to enhance the value of his later palaeontological work.

Hopwood graduated with second class honours in 1922 and proceeded to his doctorate in 1933. On graduation he was the holder of a Mark Stirrup scholarship in palaeontology, and he later served for a time on the Indian Geological Survey.

In 1924 he was appointed to the staff of the Department of Geology in the British Museum (Natural History) where he stayed until he retired (as principal scientific officer) in 1957. At the museum Hopwood was assigned to mammalian palaeontology, an arrangement admirably designed to make the best of his geological experience and his flair for the morphological, and justified by events: relatively soon there began to appear a series of original and joint papers on fossil mammals which earned him recognition in this field. The 1928 *Catalogue of Pontian Bovidae of Europe in the Department of Geology, British Museum (Natural History)*, in collaboration with Guy Pilgrim, was the forerunner of numerous authoritative publications contributing substantially to mammalian palaeontology. Their catholic range embraced equids, proboscideans, carnivores and various ungulates, but the most important score or so treated of fossil primates from the Miocene, Pliocene and Pleistocene of central and eastern Africa. By these, perhaps, Hopwood will be best remembered.

He immediately realized the rich significance of the Olduvai deposits, whose exploration he pioneered with Beck and Leakey and on whose mammalian fauna he pronounced perceptively. While his African palaeontological publications necessarily included the recognition and description of hitherto unknown mammalian genera and species—including the celebrated Miocene pongid, *Proconsul africanus* (erected 1933)—they also incorporated such significant considerations as the role of environmental phenomena (earth movements, ice ages, climate) in determining the physical characteristics of extinct faunas, and they showed unequivocally the contribution that palaeontology itself could make towards the elucidation of complicated geological sequences. Hopwood's knowledge of the adaptive plasticity of osseous tissue, whether in the recent or in the extinct mammal, is recognizable in his writings and it enabled him to assess any particular fossil with an acumen transcending the purely geological. With Halleyfield he epitomized much of his African work in the *Annotated Bibliography of Fossil Mammals of Africa* (1954).

Hopwood's consideration of environmental and functional factors in his approach to the palaeontological was reflected in his sustained interest in recent mammalian osteology. To this subject he gave much detailed attention, publishing a series of studies of the craniology or limb skeleton of African rhinoceroses, carnivores and antelopes. In so doing he stimulated interest in a somewhat neglected aspect of zoology, and his example has proved profitable to subsequent workers.

Preoccupation with mammalian palaeontology, however, by no means diminished his lifelong interest in the Mollusca: he was the recognized authority on the genus *Conus* and between 1930 and 1945 contributed considerably to malacological literature.

Recognized at home and overseas as an authoritative palaeontologist, taxonomist and bibliographer, Hopwood was much consulted by individuals and scientific societies. He served the Zoological Society of London on its publications committee (1944–61), as co-editor of the *Nomenclatur Zoologicus*, vol. 6 (1966), and as delegate to the zoological nomenclature colloquium held under the auspices of the Fifteenth International Congress of Zoology (1958). His long service to the Linnean Society of London saw him council member (1946–56), zoological secretary (1948–52) and twice vice-president (1947–48, 1955–56). His interest in the Mollusca gave the Malacological Society his services as council member (1930–49), secretary (1933–36) and president (1943–45). After retirement from the museum his faculty for attractive and lucid exposition found a decade's fruitful exercise as *professeur* at the Lycée Français.

Hopwood's natural endowment included a gentle, considerate disposition, a well developed artistic sense and a markedly philosophical turn of mind, much attracted to Teilhard de Chardin's concepts of natural phenomena. If occasionally, and wholly superficially, a trifle portentous, Hopwood was fundamentally a modest, merry-hearted man, perennially fascinated by the wonder of living things. An accommodating colleague and a staunch friend, he was prodigal of time and effort in assisting those who sought his counsel or his expertise. Many therefore remember him with affectionate gratitude.

Correspondence

Attitudes to Conservation

Sir,—*Nature* is right, of course, and Eliot Slater (*Nature*, **225**, 773; 1970) is wrong. All scientists in biology and medicine know, or should know, that there *is* a creed. It was stated by Pasteur as follows,

"You bring me the deepest joy that can be felt by a man whose invincible belief is that Science and Peace will triumph over Ignorance and War, that nations will unite, not to destroy, but to build, and that the future will belong to those who will have done most for suffering humanity.

Young men, have confidence in those powerful and safe methods, of which we do not yet know all the secrets. And, whatever your career may be, do not let yourselves become tainted by a deprecating and barren scepticism, do not let yourselves be discouraged by the sadness of certain hours which pass over nations. Live in the serene peace of laboratories and libraries. Say to yourselves first: 'What have I done for my instruction?' and, as you gradually advance, 'What have I done for my country?', until the time comes when you may have the immense happiness of thinking that you have contributed in some way to the progress and to the good of humanity. But, whether our efforts are or not favoured by life, let us be able to say, when we come near the great goal, 'I have done what I could'."

Since there is a creed, it is appropriate for scientists to accuse of heresies those who would thwart the needs of humanity for food and the prevention of disease. It is true that these needs both fall in the category of "Short-term expediency" in the terminology of Slater.

Slater asks, "What is the present rate of genocide, in terms of species per century?" But genocide refers to the extermination of racial, political, or cultural groups of *human beings*! Is Slater trying to extend the term to, let us say, *Salmonella typhi* and *Treponema pallidum*?

Certainly, a biologist could write, "human beings . . . may be more like ants and bees than laboratory rats"! In terms of social behavior, this is quite true. The *Hymenoptera*, and human beings, unlike rats, seldom devour their newborn young. However, perhaps human beings are changing. Slater, who has four children, says, "Right now, every new child born is an entry for the debit page, acceptable only if required for replacement".

Yours faithfully,

Thomas H. Jukes

Division of Medical Physics,
Donner Laboratory,
Berkeley, California, 94720.

Information Explosion

Sir,—It is refreshing to read Mr Bruce Sanford's letter (*Nature*, **225**, 979; 1970) which departs from the usual attitude of burying one's head in the sand in the hope that computers will solve the information explosion problem. Far too often the use of computers is voiced in the context of information retrieval but this is only part of the problem and the easiest part at that. The real problem is, as Mr Sanford implies, in the assimilation of information and the means of its conveyance to the storage media.

In this area, publishers could be of immense assistance by including in their journals informative summaries, compiled with the assistance of authors, which would enable the documentation expert to make a quicker assessment of the importance and application of an article without having, in the first instance, to read it in detail.

A genuine attempt to do this may be seen in the Ministry of Technology's TECHLINK Service. This relates to government research reports and enables the recipient to make a quick assessment of the value of a report before actually acquiring it.

No one can dispute the efficacy of computers for information storage but if they are to be used to advantage it is vital that greater attention is paid to the input stage which is still a manual operation.

Yours faithfully,

A. Johnson

"Sandown",
The Serpentine North,
Blundellsands,
Liverpool 23.

Light Carrying Electrons

Sir,—In connexion with our observation (*Phys. Rev. Letters*, **15**, 349; 1969) of the modulation of an electron wave by light (see *Nature*, **225**, 15; 1970), I would like to point out that Harris and Smith (*Nature*, **225**, 502; 1970) propose an explanation of electron bunching which, among others, we also mentioned in our paper as a possible mechanism and which was even briefly reported by your Solid State Physics Correspondent in his earlier note. In the meantime, however, even when disregarding the fact that the numbers do not check, we have come to the conclusion that the theory cannot be so simple because, if bunching were the explanation, the effect should also be observed without the presence of the thin crystalline film. However, this is not the case. There is also a continuous decrease in intensity of the light spots on the nonluminescent target with increasing distance between the thin film and the nonluminescent target.

With further experimental and theoretical studies under way, it appears that only a quantum mechanical theory can explain the effect.

Yours faithfully,

Helmut Schwarz

Rensselaer Polytechnic Institute,
East Windsor Hill,
Connecticut, 06028.

Anonymous Bounty

SIR,—Under the heading "Anonymous Bounty" (*Nature*, **225**, 783; 1970) you refer to the endowment fund of £250,000 given to the World Wildlife Fund, with the comment that the donor "gave no stipulation as to how the money should be spent". I would like to stress that the £250,000 itself cannot be spent at all—only the much more modest income from it.

Nevertheless the high priority projects for which we hope to find funds in 1970 include the following: the work of the Legislation Commission of the International Union for Conservation of Nature and Natural Resources in preparing an "International Convention on Export, Import and Transit of Certain Species of Wild Animals and Plants", the work of the International Wildfowl Research Bureau in preparing an "International Wetland Convention" designed to preserve marshes and their plant and animal communities; the work of the Advisory Committee on Oil Pollution, and of the International Council for Bird Preservation towards prevention of oil pollution; the work of the Charles Darwin Foundation for the Galapagos Islands in averting the extinction of the endemic flora and fauna, so much of which is of spectacular interest; the work of the Survival Service Commission of IUCN for threatened species, especially at the moment for apes, big cats, polar bears, wild cattle, rhinoceroses, sirenians, whales, the monkey-eating eagle, the white-winged wood duck, the Hawaiian goose, the cranes and the bustards, marine turtles, crocodiles and threatened plant species; a major conservation programme for Madagascar's unique fauna and flora; support for the 4,800 square miles of Manu National Park, an unspoiled valley in the Andes of Peru; support for the Cayapas Reserve in Ecuador; and the Awash National Park in Ethiopia; and the Shimba Hills in Kenya; the acquisition of a reserve area in the Papuan Gulf, New Guinea; the acquisition of marshlands at Marchauen in Austria; a concerted effort to save the tamaraw (the Philippine wild ox) and the kouprey (the Cambodian wild ox) from extinction; a management plan and survey of the Nile crocodile in Ethiopia and the marine turtles on the SE coast of Africa; a conservation programme for the great Indian bustard; a motor launch and equipment for the research station at Aldabra; a continuing scientific presence and programme for the Udjung Kulon Reserve in Java (where the last 25–28 Javan rhinos survive), and a comparable programme for the mountain gorilla in Rwanda and the Congo; support for the Marine National Park of Kenya; and for a bird observatory at Lake Nakuru, Kenya. Financial help for conservation is urgently needed in Indonesia, Sudan, India and Pakistan, and particularly for the College of African Wildlife Management at Mweka, Tanzania, and the School for the Training of Wildlife Specialists at Garoua, Cameroon. In Israel support is needed for a very large and imaginative programme of Field Study Centres for Conservation. Immediate help is also needed to save a number of oceanic islands from total degradation.

In the UK there are projects for land acquisition and reserve establishment in the following places: on the Ouse Washes in Norfolk and Cambridgeshire; at Martin Mere, Lancashire; on the Glen Washes, Lincolnshire; at Caerlaverock on the Solway Firth; at Predannack, Cornwall; at North Hill Tor, Glamorgan; near Hickling Broad, Norfolk; at Great Merrible Wood, Fox Covert and Poultney Wood in Leicestershire; at Colne Point, Essex; at Bix Bottom, Oxfordshire; and at Lower Whetmoor Woods, Gloucestershire. There is a project for the study and conservation of the large blue butterfly—probably Britain's most prominent species threatened with world extinction. Educational projects are required for Wicken Fen, Strangford Lough, and Fair Isle; and there is a research project on the disappearing sand lizard. There are some 16 nature reserve areas in Scotland which need support and this will be done through the Scottish Wildlife Trust.

I hope I may have made the point that a good deal more money is needed. Some of these projects may not seem very important in isolation, but if all can be undertaken they will add up to a significant amount of solid conservation achievement.

Yours faithfully,

PETER SCOTT

Slimbridge,
Gloucestershire.

University News

Dr T. F. Slater, University College Hospital Medical School, has been appointed to the newly established chair of biochemistry at **Brunel University.**

The title of **Professor of Chemical Pathology** has been conferred on **Dr F. V. Flynn** in respect of his post at University College Hospital Medical School, London, and that of **Reader in Mechanical Engineering** on **Dr R. M. Davies** in respect of his post at University College London.

Announcements

Five new members have been elected to the board of trustees of the **Salk Institute: Dr A. F. Brimmer,** US Federal Reserve Board; **Dr A. Hammer,** Occidental Petroleum Corporation; **Masaru Ibuka,** Sony Corporation; **Dr Seiji Kaya,** University of Tokyo; **Dr Norman H. Topping,** University of Southern California.

The fifth **Founders medal** of the US National Academy of Engineering has been awarded to **Professor Charles Stark Draper** of MIT.

The Council of the Royal Society has awarded the **John Murray travelling studentship** for 1970 to **Professor F. Oldfield,** New University of Ulster, to enable him to carry out research on recent productivity changes in eutrophic lakes.

ERRATUM. In the article "Growing Pains in British Universities" (*Nature*, **225**, 407; 1970), the second and third sentences in the third paragraph should read: "Fig. 1 shows that between 1959 and 1965, expenditure increased at an average annual rate of about 18 per cent, while student numbers rose by about 7 per cent a year. But after 1965, when Colleges of Advanced Technology received university status, the increase in expenditure seems to have been reduced to about 9 per cent a year, while student numbers continued to rise at an average yearly rate of about 8 per cent".

ERRATUM. In the article "Stimulation by Cyclic AMP of Intrinsic Protein Kinase Activity in Ox Brain Membrane Preparations", by M. Weller and R. Rodnight (*Nature*, **225**, 187; 1970), the ordinate of Fig. 1 should read: nmoles [^{32}P]-phosphorylserine/mg protein.

International Meetings

September 27–October 1, **Congress of the International Society for Fat Research,** Chicago (Dr F. Bradley, 136 Sharps Lane, Ruislip, Middlesex).

September 27–October 2, **Second Harden Conference,** Ashford, Kent (Dr A. P. Mathias, Department of Biochemistry, University College, Gower Street, London WC1).

September 28–October 2, **Gas Chromatography,** Dublin (The Conference Secretary, Institute of Petroleum, 61 New Cavendish Street, London WIM 2AR).

September 29–October 1, **Advances in Polymer Sciences and Technology,** London (R. H. Craven, Institution of the Rubber Industry, 4 Kensington Palace Gardens, London W8).

October 4–9, **Annual Meeting of the American Society for Information Science,** Philadelphia (ASIS, 2011 Eye Street, NW, Washington, DC, 20006, USA).

October 5–7, **Gallium Arsenide and Related Compounds,** Aachen (Conference Secretariat, Technische Hochschule Aachen, 5100 Aachen, Templergraben 55, Germany).

October 5–9, **Plutonium and Other Actinides,** Santa Fe (Dr A. E. Kay, Head of Research Metallurgy, Atomic Weapons Research Establishment, Aldermaston, Reading RG7 4PR).

October 6–10, **International Science Exhibition,** London (R. W. Boardman (Exhibitions), Ltd, 8 Leicester Street, Leicester Square, London WC2).

October 15–16, **Tuberculosis,** Bucharest (Secretariat, Union of Societies of Medical Sciences in the Socialist Republic of Romania, Progresului 8–10, Bucharest, Romania).

October 19–21, **Antimicrobial Agents and Chemotherapy,** Chicago (R. W. Sarber, American Society for Microbiology, 115 Huron View Boulevard, Ann Arbor, Michigan 48103, USA).

Sabbatical Itinerants

In the hope of providing some practical assistance in the good cause of mobility between laboratories, *Nature* advertises the needs for housing of families about to take up periods of sabbatical leave. To begin with, no charge will be made for advertisements like this. It is hoped that a period of experiment will show what form these advertisements could most usefully take and whether they are effective.

To Let: June and July 1970. 3–4 bedroom house near Epsom; only 32 minutes to Waterloo Station. Would exchange for similar near La Salpêtrière Hospital, Paris, if possible. Please contact Dr L. Herzberg, Neurology Department, St Thomas' Hospital, London SE1 (01-928 9292).

Vacant: Four bedroomed, centrally heated house, fully furnished in Harpenden, Hertfordshire (London 30 minutes). Available from September 1, 1970, for one year. Use of car may be arranged. Please contact: T. I. Kilenyi, Department of Geology, Sir John Cass College, Jewry Street, London EC3.

Wanted: Furnished 2-bedroom flat or house for American professor and family (two children, 18 and 20 years) within half-hour central London, rent no more than £50 per month, in exchange for 2-bedroom house (with 3rd spare room) in Laguna Beach, California, overlooking town and sea, from June 15 to September 1. No money involved. Please contact Dr Hannah Steinberg, Department of Pharmacology, University College London, Gower Street, London WC1.

Wanted: Furnished house or apartment in London area for university professor, wife and three daughters for 9–12 months beginning in the summer or autumn of 1970. Can offer a 4-double-bedroomed house in Denver, Colorado, in exchange for same or longer period. Please contact Dr M. Moskowitz, Clinical Research Centre, Mill Hill, London NW7.

British Diary

Monday, March 23

Digital Filters (6.30 p.m.) Mr R. C. V. Macario, Institution of Electronic and Radio Engineers; and the Institution of Electrical Engineers; at the University of Wales Institute of Science and Technology, Cardiff.

Electrical Aspects of Spacecraft (7.30 p.m.) Mr H. J. H. Sketch, Institution of Electrical Engineers, at the J. J. Thomson Laboratory, University of Reading, Whiteknights Park, Reading.

Integrated Management Systems in Manufacture (5.30 p.m.) Mr F. N. Stephenson, Institution of Electrical Engineers, jointly with the Institute of Management and Control and the I.Mech.E., at Savoy Place, London WC2.

Machinery Requirements for Expanded Plastics Production (6.30 p.m.) Plastics Institute, at the Coachmakers' Arms, 88 Marylebone Lane, London W1.

Memorial Service for Lord Jackson of Burnley, FRS (12 noon) at Holy Trinity Church, Prince Consort Road, London SW7.

Newer Polymers (10 a.m. symposium) Society of Chemical Industry, Plastics and Polymer Group, in Physics Lecture Theatre 1, Imperial College, London SW7.

Overhead-line Oscillations and the Effect of Aerodynamic Dampers (5.30 p.m.) Mr J. C. R. Hunt and Mr D. J. W. Richards, Institution of Electrical Engineers, at Savoy Place, London WC2.

Structural Dynamics (three-day symposium) Loughborough University of Technology, in association with the British Acoustical Society; the Institution of Civil Engineers; the Institution of Mechanical Engineers; and the Royal Aeronautical Society, at the University.

The Biochemistry of Steroid Hormone Action; Cerebral Enzymes and Isoenzymes; Membrane-bound Enzymes; Mitochondria and Calcium Transport, Professor A. L. Lehninger (Fifth Jubilee Lecture) (two-day meeting) Biochemical Society, at University College London, Gower Street, London WC1.

The Dielectric Properties of Heterogeneous Systems including Biological Materials (three-day meeting) Dielectrics Discussion Group, at the University College of Wales, Aberystwyth.

The Shape of Things: General Conceptions of the Nature of Things (7.45 p.m.) Mr Ian Ross, H. G. Wells Society, in the Common Room of the Electrical Engineering Department, Imperial College, Exhibition Road, London SW7.

Tuesday, March 24

Adhesion, Adhesives and Fibres (6 p.m.) Mr E. W. Garnish, Society of Chemical Industry, Paper and Textiles Group, at 14 Belgrave Square, London SW1.

ATLAS Language (5.30 p.m.) Mr J. A. Hill, Mr A. Hann and Mr A. H. Parker, Institution of Electrical Engineers, at Savoy Place, London WC2.

Automation in Air Traffic Control (6.30 p.m.) Mr A. Hartley-Smith, Institution of Electronic and Radio Engineers, at Havering Technical College, Hornchurch, Essex.

On Load Corrosion on No. 1 Boiler at Portabello Power Station (6 p.m. discussion) Institution of Mechanical Engineers, Steam Plant Group, at 1 Birdcage Walk, London SW1.

Wednesday, March 25

Computers and What They Can Do (1.10 p.m.) Professor Victor Price, City University, at the Graduate Business Centre, Gresham College, Basinghall Street, London EC2.

Extrusion Machinery (7.30 p.m.) Institution of the Rubber Industry; and the Plastics Institute, at the Queen's Hotel, Hull.

Integrated Iron and Steel Works as Responsible Producers and Converters of Energy (6 p.m.) Sir Henry Clay, Institution of Mechanical Engineers, at 1 Birdcage Walk, London SW1. (Sixth John Player Lecture.)

MCT-Margarine, a Tailormade Fat Composition with Respect to Physiology and Consistency (6.15 p.m.) Professor G. Billek, Society of Chemical Industry, Oils and Fats Group, at 14 Belgrave Square, London SW1.

Our Professional Duties. Problems in Establishing a Potash Industry in the North Yorkshire National Park (5.30 p.m.) Sir Frederick Warner, Society of Chemical Industry, at the University of Leeds. (9th Brotherton Memorial Lecture.)

Peripheral Development and Information Flows Inside Systems (2.30 p.m. colloquium) Institution of Electronic and Radio Engineers, Joint IERE/IEE Computer Group, at 9 Bedford Square, London WC1.

Recent Advances in Analytical Chemistry (10 a.m. symposium) Chemica Society; Royal Institute of Chemistry; Society of Chemical Industry; Society of Dyers and Colourists; and the Society for Analytical Chemistry, at University of Manchester Institute of Science and Technology, Sackville Street, Manchester 1.

Silicon Imaging Devices (2.30 p.m. discussion) Institution of Electrical Engineers, at Savoy Place, London WC2.

The Victoria Line and its Successors (5.30 p.m.) Mr R. M. Robbins, Institution of Electrical Engineers, at Savoy Place, London WC2.

Vacuum Forming (7 p.m.) Mr G. W. Robertson, Plastics Institute, at St. Johns Hotel, Solihull.

Thursday, March 26

Adhesives and Adhesion (7 p.m.) Mr N. C. MacDonald, Oil and Colour Chemists' Association, at the Manor Hotel, Datchet, Bucks.

The Protection of Rubber and Plastics Against Degradation (7.30 p.m.) Mr G. E. Williams, Institution of the Rubber Industry, at the Scottish Building Centre, 425 Sauchiehall Street, Glasgow C2.

Monday, March 30

Rubber Blank Preparation (6.45 p.m.) Mr P. D. Lanham, Institution of the Rubber Industry, at the Waldorf Hotel, Cooper Street, Manchester 2.

HOW TO BUY NATURE

Volumes start in January, April, July and October but subscriptions may begin with any issue.

The direct postal price per subscription for one copy of NATURE each week is:

12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire.............................. **£14.0.0 each**
United States of America........(by air freight)............**$48 each**
Canada..........................(by air freight)..........**$52 each**
Elsewhere overseas by surface mail....................**£14.0.0 each**
(Charge for delivery by air mail on application)
*Shorter periods *pro rata*. (Minimum three months.)

Points you should know about the EM802

An electron microscope for universal application

The EM802 combines in one instrument all the facilities you need, whatever your field of research.

There is no loss of performance and no 'down-time' when changing from one mode of operation to another. The EM802 continues the long tradition of AEI for simplicity of operation.

To judge the 802 for yourself, come and use one at your leisure in our Consultant Laboratory. Ring Jay Bailey (Harlow 26761), or write, to fix a suitable time.

1. Goniometer stage allows 5 Å resolution even at the highest angle of tilt.
2. Push-button selected area diffraction at various camera lengths.
3. Push-button selection of bright or dark field images by all-electrical beam deflector with independent astigmatism correction.
4. Multi-purpose specimen chamber to meet a wide range of applications at high resolution.
5. Selected area diffraction facilities.
6. Anticontaminators.
7. Automated vacuum system.
8. Push-button controls.
9. Space for accessory control modules.

APPOINTMENTS VACANT

FOOD RESEARCH

THE FRUIT AND VEGETABLE PRESERVATION R.A.

Vacancies exist at various levels for

TECHNOLOGISTS, MICROBIOLOGISTS, PHYSICISTS AND ENGINEERS

The work of the station is concerned with the range of fruit and vegetable processing and involves many disciplines.

Job specifications, salary scales, etc., available on application to the Director, Campden Research Station, Chipping Campden, Glos.

(1203)

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

(UNIVERSITY OF READING)

BACTERIOLOGY DEPARTMENT

Immunologist or Biochemist required to study antibody production in ruminants; if necessary, training in the appropriate discipline will be arranged. The particular emphasis of the study will be on the protective role of secretory immunoglobulins in the alimentary tract of the young animal. Opportunities exist for the successful candidate to obtain a higher degree. The appointment will initially be for a period of three years, but future prospects are excellent for the right applicant. Salary scale, as Scientific Officer, £1,071 to £1,827; entry point dependent on age and experience. F.S.S.U.

Applications, on forms obtainable from the Secretary, N.I.R.D., Shinfield, Reading RG2 9AT, are invited from honours graduates. Quote: ref. 70/11. (1042)

UNIVERSITY OF OXFORD

RESEARCH OFFICER IN OPHTHALMIC BIOCHEMISTRY

A vacancy exists in the Nuffield Laboratory of Ophthalmology for a biochemist interested in study of biochemistry of the eye. Salary on the scale £1,885 to £2,725 per annum plus F.S.S.U. The appointment is for five years and is renewable. Topics currently being studied include enzymes and proteins of the normal and cataractous lens and the experimental production of lens opacities.

Applications (five copies, or one from overseas candidates), stating age, qualifications and experience, with a list of publications and names and addresses of two referees should reach the administrator, Nuffield Laboratory of Ophthalmology, Walton Street, Oxford, OX2 6AW (from whom further particulars may be obtained) by April 25, 1970. (1048)

Electricity Council Research Centre

PHYSICISTS

We are interested in a wide range of studies in interior domestic environments – (also offices, works, hospitals, etc.).

Specifically, we want to recruit Physicists for further studies in *Lighting* such environments, and further studies in the *Control* and *Instrumentation* of practical environments.

An interest in working in these topics coupled with a good physics or engineering degree is required. For one post, post-graduate experience of electronics is an additional requirement.

Salary on appointment, depending on ability, experience and age, will be within one of the following bands:

£1,173-£2,001 £2,184-£2,951
£1,920-£2,442 £2,904-£3,595

NJB Agreement

Please apply to: D. C. Page,
Head of Personnel Services,
Electricity Council
Research Centre,
Capenhurst, Near Chester,
quoting ref. No. N/222

(1186)

ROYAL ARMY MEDICAL COLLEGE

Ministry of Defence (Army Department)

Millbank, London, S.W.1.

PARASITOLOGIST (graded Experimental Officer/Assistant Experimental Officer) for preparation of pathology class-room for practical classes, meetings and demonstrations involving human Protozoology and Helminthology; maintenance of parasitological specimens and biological material; the setting out of macroscopic and microscopic demonstrations, and undertaking related duties including assisting in the practical tuition in parasitology of medical officers and laboratory technicians. Successful candidate may also undertake practical work in diagnosis of parasitic diseases and will have opportunities to assist in research. Duties may include work with experimental animals.

Qualifications: Degree, or equivalent in appropriate subject. Age: A.E.O. under 28; E.O. normally 26-30.

Salary: E.O. £1,590-£2,006; A.E.O. £940 (at 22)-£1,208 (at 26)-£1,454. London weighting £125.

Prospects of permanent pensionable appointment.

APPLICATION FORMS are obtainable from the Ministry of Defence (Army Department), CE2(F)(AD), Room 304 Northumberland House, Northumberland Avenue, London, WC2. **Please quote: 4/70/G.**

(1142)

ST. MARY'S HOSPITAL MEDICAL SCHOOL

(UNIVERSITY OF LONDON)

PADDINGTON, W.2

Applications are invited for a new post of

SENIOR LECTURER OR LECTURER IN BIOCHEMISTRY

established in co-operation with the Ministry of Overseas Development to assist overseas universities. The successful candidate will be a full member of the staff of the Biochemistry Department but will be expected to spend the greater part of his service on secondment overseas, mainly at the Department of Biochemistry, University of Ibadan, Nigeria, for five years.

Salary scales: Senior Lecturer, £2,770 to £3,670 plus £80 L.A.; Lecturer, £1,240 to £2,850 plus £60 L.A., together with superannuation under F.S.S.U. and overseas allowance as appropriate to the particular assignment.

Applications (two copies), together with the names of two referees, should be sent by April 30, to the Secretary, from whom further particulars should first be obtained.

(1123)

THE UNIVERSITY OF SUSSEX

SCHOOL OF BIOLOGICAL SCIENCES

LECTURESHIP IN NEUROBIOLOGY

To assist in the teaching of a new degree course in Neurobiology with special responsibilities for functional neuroanatomy for either 1970/71 or 1971/72.

Applicants with interests in other areas of neurobiology will be considered. The course is jointly organised by biologists and experimental psychologists within the School of Biological Sciences. Studies of brain function in a wide range of disciplines are actively pursued in the School and the Biology group within which the appointment would be made, intends to develop neuroanatomical approaches to studies of vertebrate motor control and motivation.

Salary will be within the range £1,240 to £2,850 per annum plus F.S.S.U. benefits.

Application forms should be obtained from the Secretary of Science, Science Office (Establishment), The University of Sussex, Falmer, Brighton, BN1 9QH. Any inquiries should be made direct to Professor R. J. Andrew.

(1190)

THE OPEN UNIVERSITY

RESEARCH STUDENTSHIP IN BIOLOGY

The Research Student will work under Professor Steven Rose on aspects of the Biochemical correlates of learning and environmental change; and will be able to register as a postgraduate student for a Higher Degree of the Open University. The value of the Studentship will be not less than £530 per annum.

JUNIOR TECHNICIAN IN BIOLOGY

To work partly in the Biological and Biochemical laboratory and partly in the Animal House. Salary at a point on the scale £377 to £637 per annum.

Detailed applications, with names and addresses of two referees, should reach the Establishments Office (3), The Open University, Walton Hall, Walton, Bletchley, Bucks, by Monday, April 6, 1970.

(1204)

QUALIFIED CHEMIST

[Female]

FOR TECHNICAL LIBRARY

We wish to appoint a chemist in our library in Birmingham to undertake the classification and indexing of information, the preparation of abstracts and literature searching.

Applicants must possess an honours degree, or be an Associate of the Royal Institute of Chemistry. Preference will be given to applicants with previous experience of information work, and a knowledge of French or German would be an advantage.

Starting salary from £1200, depending upon age and experience.

Please write for full Job Description and application form to:—

The Personnel Manager (Ref: HSP),
Thermosetting Division,
Bakelite Xylonite Limited, Redfern Road,
Tyseley, Birmingham 11.

BXL

BAKELITE XYLONITE LIMITED

(1212)

TROPICAL PRODUCTS INSTITUTE
MINISTRY OF OVERSEAS DEVELOPMENT
56-62 Grays Inn Road London WC1

Microbiologist

MICROBIOLOGIST (graded Senior Scientific Officer) to take charge of the Microbiology and Fermentation Section of the Institute. A major part of the responsibility will be to continue the Institute's pioneering researches into the microbial production of protein from nutritionally inferior carbohydrate foodstuffs, such as cassava. This work forms a part of the UK contribution to the International Biological Programme. The Section is also responsible for investigational work on the microbial deterioration of foodstuffs and for dealing with enquiries from developing countries on a wide variety of bacteriological problems in foods of tropical origin.

The successful candidate may be required to undertake occasional short term overseas visits.

Qualifications: 1st or 2nd class honours degree in microbiology and at least 3 years' post-graduate experience. Ability to conduct independent research in this subject necessary. Experience of research relevant to the production of micro-organisms in bulk and of the fermentation industries an advantage. Knowledge of microbiological control in relation to foodstuffs desirable. Age: SSO normally 26-31.

Salary: £2,146-£2,616.

Prospects of permanent pensionable appointment. Prospects of promotion.

APPLICATION FORMS from the Administrative Secretary at the above address.

(1119)

AKZO

Centrale Engineering Amsterdam, Netherlands

expert in thermodynamics or physical chemistry

The Chemical Engineering Development Department at Hengelo (Holland) has an opening for an Engineer or a physical chemist with special knowledge of thermodynamics. The development of chemical processes from the laboratory to industrial plants requires knowledge and experience in the application of thermodynamic theories and calculations, especially in the field of the phaserules. Distillation calculations for the separation of multicomponent systems call for advanced mathematical methods and the use of computers.
To a scientist (graduate of an institute of technology or a university) sufficiently interested in these fields this opening offers an interesting scope of work; having given proof of his capability he will work highly independent and be entrusted with a large measure of responsibility. Applications in writing with recent passport photograph should be addressed to: Centrale Engineering Amsterdam, Dept. Personeelszaken, Sloterweg 11, Amsterdam-W, Netherlands.

AKZO incorporates the activities of a large number of companies, both national and international, manufacturing synthetic fibres and a great variety of chemical and petro chemical products as well as foodstuffs, paints, lacquers and pharmaceuticals.

RECENT SCIENTIFIC AND TECHNICAL BOOKS XXI

Nature in North America: The *Nature* office in Washington DC has opened and contributors in the United States and Canada are invited to submit manuscripts for publication either to the address given below or to the present London office. The intention is that each office will be able to answer inquiries about all manuscripts and other matters. This is one of several steps by which it is hoped to provide a better service for readers and contributors.

UV Spectrophotometers
make light work

What does this mean to you? In research, results you can trust and repeat. In routine applications, error-free operation by the least experienced member of your staff.

When you come to Pye Unicam, even the selection of your UV spectrophotometer is simple. There is a choice of instruments broad enough to meet your every requirement and to match your budget, with a staff of experienced application specialists to back them up.

Just look at what is available . . . **SP500 Series 2** and **SP600 Series 2** quantitative single beam spectrophotometers, **SP700** for research, **SP1800** for low-cost double-beam operation, **SP3000** automatic digital instrument, **SP8000** for the ultimate in flexibility, and th **SP1300 Series 2** low-cost colorimeter.

Write or 'phone for free information today. That's simple too, isn't it.

HOW TO MAKE 100 μV SENSITIVITY AND 50 μV DRIFT LIVE HAPPILY TOGETHER IN A LOW FREQUENCY SCOPE

Easy. We've done it twice at Hewlett-Packard. In the 1200A 2-channel and the 1202A 1-channel scopes. The answer? All solid state circuitry with matched FET inputs.

Typical drift at the 100 μV level is reduced to less than 50 μV per hour. Trace shifts due to shocks or vibrations are eliminated. Noise is less than 50 μV P-P at the full 500 kHz bandwidth and may be reduced to as low as 15 μV P-P by means of a bandwidth limit switch. Other features of the 1200A/1202A series include: 17 calibrated sensitivity ranges with full bandwidth at all ranges, large 8 x 10 cm CRT with internal graticule to eliminate parallax, 100 db common mode rejection, single-ended or differential input on all ranges, perfectly stable input balance, complete triggering versatility, external horizontal input, beamfinder and d-c coupled z-axis input.

Both the 2-channel 1200A (price £ 454) and the 1-channel 1202A (price £ 421) are also available in 5¼" high rack mounts.

If you are looking for accurate, stable measurement at low levels, then write to your local HP office for the full specifications, on these new, high-performance LF scopes.

NATURE Volume 225
MARCH 28, 1970

Senator Mansfield, His Mark

THE irony of the scandal which has arisen in the United States (see page 1185) about the continued financing of basic research originally supported by mission oriented agencies is that Senator Mansfield, to whom belongs section 203 of the defence appropriations bill for 1970, is essentially a liberal man. His quarrel last December was with the Pentagon, not with American science. In other circumstances, it is easy to see how he could have been the champion of academic research, for is it not one of the ways in which the United States has become not merely economically overwhelming but intellectually important? The first conclusion, then, is that it is not the senator who should be reformed, but the system.

What has now happened in the United States is that the Congress has imposed a test of relevance on the scientific research which may be supported by the mission oriented agencies, and there is a danger that the result may be such a rapid shift of emphasis that many parts of science will be seriously harmed. Although the budgets of the two agencies—the National Science Foundation and the National Institutes of Health—which are chiefly responsible for detached research have been increased, the increase is not enough to keep pace with the inflation of two years and certainly not enough to make sure that the research projects being abandoned by the mission agencies will be continued. And it is always possible that Congress will cut back the funds asked for by the National Science Foundation and the National Institutes of Health—the foundation has usually been unlucky.

The first thing to be said is that, in principle, it is entirely proper that there should be a shift from the American tradition that most basic research is a pensioner of mission oriented activity to one in which it is supported for its own sake. For several years it has been assumed that the National Science Foundation should be a haven of last resort, able to hold the ring between the richer agencies to which the support of academic research is a peripheral activity, and even now the foundation accounts for only 14 per cent of government support for academic science. The boot should properly be on the other foot, and the National Science Foundation should be able to provide for the hard core of academic science, not just the frosting on the cake. The demand by the congressional panel (see page 1186) that the right of mission agencies to support academic research should be regarded as a permanency is therefore mistaken—indeed, it is already intolerable that the National Aeronautics and Space Administration should be the chief supporter of academic research in astronomy simply because congressmen do not know the difference between that and space research. In the same way, it is shabby that in the coming year the US Atomic Energy Commission should have had to withdraw support from the accelerator operated jointly by Princeton and the University of Pennsylvania so as to accommodate the new 200 GeV accelerator within a more or less fixed budget.

This is why the most serious failure of the past few years has been the indifference of the Administration to the need for a greater concentration of support for basic research on agencies which are explicitly concerned with that. There have been suggestions that the National Science Foundation should grow, in the course of time, but neither the Administration as a whole nor the Office of Science and Technology has ever given a strong lead. What proportion should be the target? To be sure, there are difficulties. Many of the committees of Congress, for example, would resist the notion that exciting areas of research should become the property, so to speak, of others. It is also likely that the mission oriented agencies would resist a concentration of responsibility for basic research elsewhere, but the national interest that agencies such as the Department of Defense should have strong links with basic science can be safeguarded in other ways. And what, in any case, are administrations for if not to work out a rational balance between the necessarily conflicting interests of different agencies? Is Congress really able to prevent the Administration making up its own mind about the headings under which it applies for public money? One sign of the Administration's weakness on this issue is that it has so far conspicuously shied away from comment on the two reports produced by the National Science Board, the first of which, a year ago, argued the case for an explicit federal commitment to graduate education, and the second, only a few weeks ago, asked for just the concentration of resources in the National Science Foundation now shown to be urgently necessary.

But should the concentration of resources go as far as a government department, with a Secretary for Science and Technology able to rub shoulders (and break lances) with the big departments? This has often been advocated as a solution for problems like those of the present. The chances are that it would go too far. In strictly administrative terms, the immediate need is modest. Some way has to be found for providing continuity and a good sense of priorities in the spending of $1,600 million a year directly in universities and a comparable sum on the support of laboratories such as the great accelerator centres and the observatories which are widely used by academics. A suitably strengthened National Science Foundation should be able to manage well enough. For the time being it will be quite sufficient if the machinery which exists can be put to better use.

Prospects for SALT

THE way in which the Soviet Union and the United States are both making public statements about strategic weapons is at least a sign that both of them are prepared to stake a lot on the next round of SALT talks, which resume in Vienna on April 16. That, at least, is some small comfort. The danger, also by now apparent, is that both sides may go so far in their preliminary posturings that they will find themselves committed to needlessly bellicose policies if the talks should come to nothing. This is why it is important that everybody, not just the participants, should appreciate what has been happening, in the past few months, to the declaration of military policy in the United States and the Soviet Union.

In the United States, the most striking change has been the public acknowledgment by the Secretary of Defense, Mr Melvin Laird, that the old strategic supremacy of the United States has been melting away, chiefly because of the pace of military development in the Soviet Union. Thus Mr Laird told the congressional committees on February 20 that the Soviet Union now has more "operational" launchers for long-range ballistic missiles than has the United States, although it seems clear that the sites concerned will not be equipped with rockets for a long time yet. By the mid-seventies, however, according to Mr Laird, the tables could have been turned, which is why "we are proceeding with a program to place MIRVs (Multiple Independent Reentry Vehicles) on our Minuteman and Poseidon missiles". By all accounts, Mr Laird had not meant his colleague Dr Robert Seamans to say, a few days afterwards, that the installation of the Minuteman III missiles, which carry multiple warheads, had already begun, but that is no great surprise—the Department of Defense has not been testing all those warheads underground for the fun of it. The fact that Mr Laird has also raised, in his request to Congress for money, the prospect of adding another site to the two at which anti-ballistic missiles are already being deployed raises other issues. For one thing, it is significant that the United States Government has now entirely abandoned Mr McNamara's patently thin argument that anti-ballistic missiles were a necessary insurance against the possibility that an irresponsible attack by the Chinese could set the world in flames—now, the argument goes, the ABMs are necessary to help make less vulnerable to a first strike the Minuteman missiles which form the largest part of the land-based strategic striking force of the United States. The snag, which Mr Laird himself admitted, is that even a full deployment of the Safeguard ABM system, involving twelve and not three sites, would not guarantee immunity from an attack by the Soviet Union. In circumstances like these, it is only reasonable to expect that the United States Congress will give the ABM proposals an even closer scrutiny than they received last year, when the President's cause scraped through with only the narrowest of margins.

For students of strategic armaments, Mr Laird's statement on February 20 also contains some alarming news of the pace of change in fields which have recently seemed comparatively stable. One strategically puzzling development is the decision to build a supersonic strategic bomber—it will be interesting to see whether the Department of Defense has better luck than the British Government with the TSR2. More significant, there is also a plan to equip nuclear submarines with missiles of such long range that the launching vehicles can stay permanently submerged within the coastal waters of the United States, there remaining more or less free from attack by the increasingly capable hunter submarines. This, in the long run, will be the tendency in all countries with strategic pretensions.

Developments like these are, of course, enough to persuade observers outside the United States that a new period of military innovation has begun. This, certainly, is what *Pravda* has been saying, most conspicuously on March 7. And it is clear that some of these developments are unstoppable—the MIRVs and the submarines cannot be identified from the outside, for example. It is therefore only fair to say that the Soviet Union has itself done much to encourage the sense of bellicosity which now seems such a tasteless preliminary to the SALT negotiations. It is therefore as well to remember that the Soviet Union has been testing warheads underground with all the abandon of the United States, and has also been claiming that there is an anti-ballistic missile system capable of destroying hostile ballistic rockets from the United States. The truth, mercifully, seems to be simply that work has begun on the building of a rudimentary defensive system about Moscow. And on balance, in spite of Mr Laird's somewhat dramatic talk about the "technological threat" from the increasing pace of research in the Soviet Union, it is probably a simple truth, for the next several years at least, that the United States is in a strong position to anticipate and outwit any strategic innovations of which the Soviet Union may be capable.

What does this imply for the resumption of the SALT negotiations? Especially because the matter is important, there is much to be said for making a dispassionate appraisal of what may emerge. A few simple facts stand out. For one thing, it is inconceivable that any agreement at Vienna in 1970 will allow for mutual inspection of military equipment in the major powers, which in turn implies that any decision not to deploy multiple warheads will have to be taken on trust by the two sides. Most probably, neither will think this to be a justifiable risk, which in turn implies that people had better behave as if that opportunity has already been lost. The fact that the Soviet Union seems not to have got very far with the deployment of these instruments is beside the point—the testing has been done.

A second simple truth is that the quality of intelligence seems now to be good enough to allow governments to count each others' launching sites without actually paying visits to them. Satellites have no doubt played a part in this, although it may be less than some enthusiasts have liked to think. In practice, however, this means that it would be feasible to think of imposing an agreed limit on the numbers of strategic ground-based missiles on each side. The ideal would be the simplest agreement—the limitation of missiles to, say, 200 on each side—enough for a retaliatory blow of great destructiveness but not enough to make a first strike seem tempting.

On the face of things, this is the best agreement that SALT could offer. Public declarations not to work towards the development of anti-ballistic missiles will be illusory—far better simply to require that each side should decide whether to put its efforts into offensive weapons or the equally destabilizing defensive rockets. There remains, however, one obvious and hopeful avenue—the extension of the test-ban to weapons tested underground. In the past few months it has become clear that the remote detection of underground explosions is more than ever feasible. In the long run, this is also the only way in which it will be possible to impede the development of advanced weapons technology. The signature of the non-proliferation treaty three weeks ago, and the willingness of the United States Government to extend its renunciation of biological weapons to include biologically derived toxins, is a sign that things are moving in a cheerful direction. Everybody will be hoping that recent bellicosity about strategic weapons is only a preliminary to hard bargaining at Vienna.

100 Years Ago

It is stated by the *Athenæum* that a new idea has been broached in a recent lecture by Mr. Bloxam, the lecturer on chemistry to the department of artillery studies. He suggests that the committee on explosives, abandoning gun cotton, should collect the germs of small-pox and similar malignant diseases, in cotton or other dust-collecting substances, and load shells with them. We should then hear of an enemy dislodged from his position by a volley of typhus, or a few rounds of Asiatic cholera. We shall expect to receive the particulars of a new "Sale of Poisons" Act, imposing the strictest regulations on the sale by chemists of packets of "cholera germs" or "small-pox seed." Probably none will be allowed to be sold without bearing the stamp of the Royal Institution, certifying that they have been examined by the microscope and are warranted to be the genuine article.

From Nature, **1**, 562, *March* 31, 1870.

OLD WORLD

LIBEL

Science in Court

A LIBEL action which has serious implications for the scientific community will be brought before the courts sometime next year. Mr Stanley Lithgow Drummond-Jackson, a dental surgeon, is suing the British Medical Association and the authors of a paper published in the association's journal, the *British Medical Journal*, because he claims that the paper is defamatory of him in the conduct of his profession. A Court of Appeal has already decided, by two votes to one, that the paper is capable of bearing a meaning likely to be damaging to the dental surgeon, and the stage is now set for what could be a long battle in the High Court.

There is more at stake in this action than the damages being claimed by Mr Drummond-Jackson, as was recently pointed out by J. R. Lewis and his colleagues (*Nature*, **225**, 1081; 1970). The case could change not only the way that scientific papers are written, but it may also deter some journals from publishing criticisms of techniques involving commercial or professional interests. The basis of Mr Drummond-Jackson's claim seems to be that the paper was critical of a technique for dental anaesthesia which was introduced, recommended and used by him, and is, therefore, closely associated with his name. The paper, which was written by Professor J. S. Robinson, Dr C. C. Wise, Dr M. J. Heath and Dr P. J. Tomlin, of the University of Birmingham, also referred to Mr Drummond-Jackson by name when citing his published papers. Such practices are, of course, common in scientific literature, and Lord Denning, Master of the Rolls, clearly saw the effect that such an action could have on the scientific community. He was reported as saying at the Court of Appeal that "it would be a sorry day if scientists were to be deterred from publishing their findings for fear of libel actions. So long as they refrained from personal attacks, they should be free to criticize the systems and techniques of others. Were it otherwise, no scientific journal would be safe" (*The Times*, February 14, 1970).

Lord Denning also said that Mr Drummond-Jackson has chosen the course of action which suits him best. The defendants must now prove the correctness of all their tests and experiments, and justify their conclusions to the jury. "To place such a burden on the defendants", he said, "should not be permitted." But the other two Appeals Court judges thought otherwise. Sir Gordon Willmer, for example, said that he could see no danger to scientific communication in dismissing the appeal, and for him the essential feature of the case seems to be that Mr Drummond-Jackson is a practising dental surgeon whose professional reputation is at stake.

The usual way of attacking the views expressed in a scientific paper is to publish another paper stating the opposing case. Such paper discussions are, of course, common among members of the scientific community, but the weapon of a libel action does not seem to have been used before to settle a scientific dispute. There are no exactly comparable legal precedents and this action may be seen by some scientists as a test case, the outcome of which could determine whether they bring similar actions in respect of papers already published.

COMPUTER POLICY

Users caught in a Vicious Circle

Delving into the obscurities of the British Government's policy toward the computer industry, as subcommittee D of the House of Commons Select Committee on Science and Technology is trying to do, is no easy matter. Last week's session saw the chairman, Mr Airey Neave, confiding how difficult it is to discern what government policy is, never mind deciding how the government should encourage the computer industry in the future. The representatives of the British Steel Corporation and Imperial Chemical Industries, both big users of computers, who appeared before the subcommittee during last week's session, served to confuse rather than clarify the situation.

One thing that is clear, however, is that the British computer company, ICL, is up against the fact that the IBM line of machines has fast become almost a standard gauge. The chief representative of the ICL team, Mr J. K. Steward, who is director of the management services division, confessed that the 2,000 man years of programming which has been invested in ICL's portfolio of computers—largely IBM machines—is a strong disincentive to change. The same sentiment was expressed by representatives of the British Steel Corporation, where, although there is rough equality between IBM and ICL, individual divisions tend to be committed to one or the other.

BSC, which appeared first, told the subcommittee of its plans to reduce the number of computers on its books by replacing them with IBM 360/40's and 360/50's. Within minutes of the changeover of places with the ICL team, however, Mr Eric Lubbock had persuaded Mr Steward to say how surprising it would be for a company to concentrate on these machines. To be fair, the BSC representatives were talking of their IBM committed divisions, beginning with the South Wales group, but if the subcommittee was looking for hints on how to run a computer installation it was clearly in for a thin time.

The representatives from BSC, led by Mr N. C. Pollock, director of management services, also drew some critical comparisons between IBM and ICL. British companies have been less reliable than IBM in the delivery of software, and the ICL business machines used by the corporation seem to break down more often (although it was not clear whether the one per cent difference in serviceability index between IBM and ICL is significant). BSC also alleged that ICL is being unnecessarily stringent in its restrictions on the competitive tapes and disks which can be used on ICL machines.

But neither team could help a great deal when it came to defining the government's present policy, although BSC thought the policy was more protectionist than statements from Mintech indicate, or deciding what government action would help computer users to break the vicious circle of dependence on IBM.

POLLUTION

Beware of the Drinking Water

Britain's water supplies could become contaminated with unusual toxic chemicals which would not show up in the routine tests conducted by water authorities. That is the conclusion of a report published last week by the Institution of Water Engineers (evidence submitted to the Central Advisory Water Committee, 10*s*), which also proposes sweeping changes in the organization of water resources.

The institution points out that chemicals of unknown toxicity are being poured into rivers and may end up in the water supplies. But water authorities are also faced with the possibility that illicit dumping and unexpected events, such as the accidental leakage of chemicals and oil from road tankers, could result in serious contamination. During the last five years 312 cases of source waters being polluted have been reported by 140 authorities. The institution estimates that about 25 per cent of Britain's water supplies are drawn from polluted waters and another 25 per cent come from rivers which are liable to sudden, unexpected pollution. The report concludes that "safety margins are becoming too narrow in relation to the increased use of frequently or heavily polluted waters for public supply sources".

The present method for dealing with unexpected pollution is that the appropriate authority is immediately notified, and steps are taken to shut off supply from the affected source. Such procedures are inadequate, the institution says, and although there can be no foolproof way of ensuring that unexpected pollutants do not enter the supply system, there is a need for more scientists, using modern laboratory equipment, to monitor the risks.

The institution is also strongly critical of the Redcliffe-Maud proposals for water supply and sewerage. It says that these "might well act adversely on the efficiency of that service and the safety of supplies", and proposes instead that authorities should be set up charged with triple responsibility for rivers, water supply and sewage disposal. Fifteen such authorities would control regional water supplies and drainage, and a Central Water and Drainage Authority would be responsible to the Minister of Housing and Local Government. The regional boards would take over the functions of the present river authorities, water undertakings and sewage disposal boards, together with the responsibilities of local authorities for sewage. The Central Board would take over the functions of the present Water Resources Board, but it would also have responsibilities for water supply and sewage disposal.

THIRD LONDON AIRPORT

Unfairness to Foulness

by our Planning Correspondent

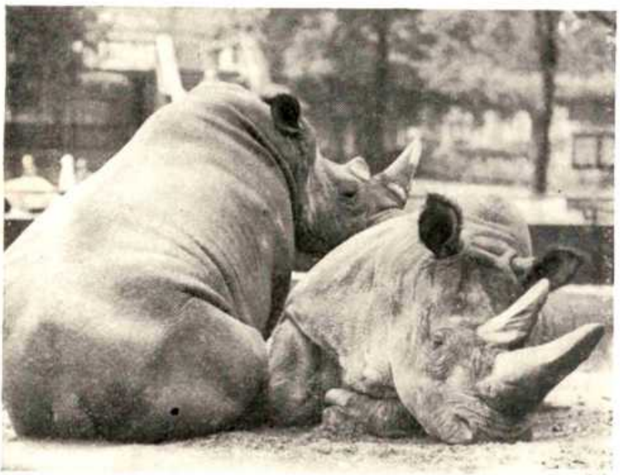
The Roskill Commission, which is looking into the siting of the third London airport, has ignored the regional advantages of siting the airport at Foulness, according to the independent research organization, Political and Economic Planning (PEP). Mr Ray Thomas and Miss Anne Whalley, who prepared the PEP evidence, say that the Roskill Commission has failed to make a full comparison of costs and benefits relevant to each of the four short-listed sites—Foulness in Essex, Nuthampstead in Hertfordshire, Cublington in Buckinghamshire and Thurleigh in Bedfordshire.

When the commuting and migration patterns of people within the four sub-regions are taken into account, the real choice before the commission, if it takes a regional point of view, is between a third London airport at Foulness, and, at the other extreme, a new national airport at Thurleigh. Cublington and Nuthampstead occupy intermediate positions. Differences in the travelling costs incurred by airport users—critical items in the Roskill Commission's study—are related to these differences in function. If Foulness were London's third airport, for example, the commission should consider the development of Elmdon or Castle Donington as an airport for the Midlands and, in such circumstances, the commission would need to reconsider airport users' travel costs.

At present, the PEP report says, the Foulness region is the most extensive dormitory area in Britain—more than 45,000 people travel daily from there to work in London—and it has an employment deficit of some 50,000 jobs. London, on the other hand, has a surplus of some 400,000 jobs. It follows that if London's third airport went to Foulness, tens of thousands of people would be given an opportunity to live nearer their place of work. For this and other reasons, most of the local authorities in Essex favour the siting of the airport at Foulness, whereas at the three inland sites there has been widespread opposition from the authorities to the siting of the airport in their area.

PEP cannot say which of the four sites is the best—it urges further research on the estimates made for critical cost–benefit items. It does, however, attempt to estimate the benefits which would accrue to the region where the airport is situated, taking into account changes in commuting patterns and the probable reductions in the levels of unemployment and under-employment. When these benefits are added up, Foulness is favoured over the other three sites by a capital sum of more than £100 million at 1968 prices.

Further sums have been calculated by the South-East Economic Planning Council which reported to the Roskill Commission last Monday. The council believes that the choice of Foulness as the site for London's third airport would cost the British taxpayer £35 million less in capital costs than would inland sites. The council's decision in favour of the coastal site, taken after a study of the regional and economic implications of a new airport there, follows the PEP and other bodies in recommending Foulness. Altogether, the evidence should provide the commission with an argument which has the air of impregnability.



Twenty white rhinoceroses are coming to Whipsnade Zoo from the Hluhluwe reserve in Natal to make up the first European breeding herd. They are of the southern square-lipped species (*Diceros s. simus*) which until recently was in danger of becoming extinct but has now joined the select number of conservation success stories. By 1966, according to the International Union for the Conservation of Nature, there were about 800 southern square-lipped rhinoceroses in the Hluhluwe and Umfolozi reserves in Natal, and about 150 more in national parks in southern Africa.

POLLUTION

Knock at Lead

Recent announcements of lead-free petrol have been prompted not because of fears that lead is a hazard to health but because it shortens the life of the catalysts used to treat automobile exhaust fumes (see *Nature*, **225**, 990; 1970). The catalytic treaters oxidize such compounds as waste hydrocarbons, carbon monoxide, and oxides of nitrogen, which are more serious pollutants, at least in the first degree, than is the tetraethyl lead that is added to petrol to inhibit knocking. Concerning the health hazard presented by lead, the Shell News Service, for example, says "at present levels there is no danger to health in the use of lead in gasoline". This view is contested in a Swedish report now published in English which concludes that "the safety margin between the present lead absorption for a person living in the city and that absorption which gives rise to chronic damage in man is apparently very small, possibly completely non-existent" (*Gasoline Containing Lead*, Lennart Danielson, Natural Science Research Council, Stockholm, S.kr.10).

Prepared for a Swedish Royal Commission on Natural Resources, the report seems to have encouraged Sweden to limit the amount of lead in petrol to 0·7 μg per litre from January 1 this year. Although this is a lenient limit that nicely corresponds to the average amount of lead already added to petrol in Sweden, there is talk of reducing the level in future.

According to the report, the amount of lead in the atmosphere—typically about 3 μg per cubic metre for a city such as Stockholm—is keeping step with the increase in the number of motor cars. As an extreme example, Danielson cites a single measurement of 71·3 μg per cubic metre on the Hollywood Freeway on a Saturday, and about 25 μg per cubic metre seems a typical value for rush hour in Los Angeles. The question is how much of this material, which is chiefly in the form of micron-sized particles that can remain suspended for about a month, is absorbed by man. Danielson claims that about half of the inhaled lead is absorbed. But the absorption of lead from food is already close to his estimate of the maximum permissible daily dose of about 5–10 μg of lead, which means that there is a good case for reducing the contribution of lead from petrol to nil. The adsorption of lead from inhaled air is estimated by Danielson as about 22 μg per day for a person breathing a concentration of 3 μg per cubic metre.

Danielson also finds fault with the conclusions of Dr R. A. Kehoe, formerly medical consultant to the Ethyl Corporation which pioneered the introduction of leaded petrol. Dr Kehoe carried out a series of experiments on the prolonged consumption of lead which seemed to indicate a safety value of 80 μg lead per 100 g of blood. (An average concentration for city dwellers is about 20 μg lead per 100 g blood.) Danielson disputes this safety value and also criticizes experiments in which Kehoe claimed to show that the lead pollution of city air is harmless.

Danielson recommends that more research should be undertaken on the accumulation of lead in the biosphere, and that the amount of lead allowed in petrol should be reduced to nothing, the phasing out taking place over five years so as to allow for the introduction of engines with low compression ratios. Essentially this is the policy which Sweden seems likely to adopt, and other countries may follow suit though for different reasons.

MEDICINE

Neutrons to treat Tumours

The first neutron generators designed to treat cancer will soon be installed at the Christie Hospital in Manchester and in the Glasgow Institute of Radiotherapy at the Belvidere Hospital. Neutron therapy may have advantages over conventional radiation therapy in treating tumours, but the difficulty in developing the technique has been to find a powerful enough source of fast neutrons. The new generating tubes may provide an effective source for routine neutron irradiation.

A prototype of the machine has been in operation in Manchester since last summer, and doctors at the Christie Hospital hope that it will be used to treat patients within the next month or so. Two commercial versions of the machine, made by Elliott Automation, will be installed in Glasgow and Manchester within the next few months. Dr J. M. A. Lenihan from the Glasgow Institute estimates that he and his staff will begin treating patients during 1971.

The neutron generating tubes, the most powerful of their kind in the world, were developed at the Services Electronics Research Laboratory, Baldock. A beam of fast, 14 MeV, neutrons is generated in a sealed tube by the deuterium–tritium reaction, and by an ingenious selection of the target material the design team has succeeded in pushing the output of the tube up to 10^{12} neutrons per second. This is high enough to be able to use the beam for therapy without unduly long treatment times, although even higher outputs would be preferable. The designers hope that they will be able to get close to the theoretical maximum of three times this figure by improving the target design.

Neutrons are already being used for cancer therapy at Hammersmith Hospital where doctors in the Medical Research Council's cyclotron unit are using neutrons generated in the cyclotron to treat patients with particularly advanced tumours. Some encouraging results have been obtained, but it is still too early to say whether the sensitivity of poorly oxygenated tumour cells to neutron radiation offers a distinct clinical advantage over X-ray or γ-ray treatment. The Hammersmith doctors are now planning a carefully controlled clinical investigation of the technique on a larger group of specially selected patients.

One difficulty in using a cyclotron to generate the neutrons is that the equipment is too expensive for most radiotherapy departments. But as Professor J. F. Fowler, at Hammersmith Hospital, pointed out, part of the cost of a cyclotron, which can be up to £0·3 million, can be borne by the other uses to which it can be put. The advantage of the new neutron therapy machine is that the generating tube is movable and also cheaper than a cyclotron—the whole installation costs about £150,000 and the replaceable tubes, which have an operating life of some 200 hours, cost only £3,000.

ARCHAEOLOGY

Real Maths

Archaeologists and mathematicians will have a fresh chance next autumn to discover how much they can help one another. The Royal Society has arranged with the Academy of the Socialist Republic of Romania to hold a conference in Bucharest on the role of mathematics in the archaeological and historical sciences, opening on September 16. Professor D. G. Kendall, director of the Statistical Laboratory at the University of Cambridge, is convinced that the conference will be "something of a novelty", not least in that it will put forward a hard sell for "real mathematics and not just arithmetic".

Fortifying archaeology with the powers of statistics in particular has a respectable history during the past decade or so, but some archaeologists seem to have retained a suspicion of mathematics. Some have a methodological bone to pick with the "statniks", to use the terminology of Jacquetta Hawkes (*Antiquity*, **42**, 255; 1968). More often, however, the problem is that some archaeologists feel out of their depth in a sea of statistics, and the view of the conference's scientific secretary, Dr F. R. Hodson, is that the Bucharest conference will help them find their feet.

The kind of "real mathematics" that can be brought to bear on archaeological problems is illustrated by Kendall's method of seriation which can be used, for example, to reconstruct the chronology of a group of tombs from stylistic variations in the pottery they contain. The Bucharest conference should pinpoint other mathematical tools for which there is an archaeological demand—cluster analysis perhaps—as well as exploring other potential applications in fields such as historical demography. Full details of the conference can be obtained from Dr F. R. Hodson at the Institute of Archaeology, 31–34 Gordon Square, London WC1.

ROYAL SOCIETY

Admissions to Carlton House Terrace

The Royal Society announced last week the batch of 32 people elected annually to join its select body. This year the 700 fellows of the society proposed some 350 candidates, the roll of which was decimated by the twelve specialist committees that mull over the candidates' claim to scientific excellence and somehow juggle their respective quotas to fill the thirty-two places. The survivors of this year's initiation rites, with one of their chief fields of interest, are as follows: C. C. Addison (University of Nottingham)—inorganic chemistry; F. F. Bonsall (University of Edinburgh)—Banach algebras; C. C. Butler (Rothamsted Experimental Station)—honey bees; R. Casey (Geological Survey, London)—Mesozoic stratigraphy and palaeontology; C. A. Clarke (University of Liverpool)—haemolytic disease in newborn infants.

J. F. Coales (University of Cambridge)—control systems; A. E. Douglas (National Research Council of Canada, Ottawa)—spectroscopy; C. Eaborn (University of Sussex)—organo-silicon compounds; I. M. Glynn (University of Cambridge)—cell membranes; J. Heslop-Harrison (University of Wisconsin)—control of sex in flowering plants; J. M. Hirst (Rothamsted Experimental Station)—control of plant diseases.

V. M. Ingram (Massachusetts Institute of Technology)—sickle-cell haemoglobin; J. C. Jaeger (Australian National University, Canberra)—rock mechanics; J. L. Jinks (University of Birmingham)—genetics of animal behaviour; B. D. Josephson (University of Cambridge)—the Josephson effect; O. A. Kerensky (Freeman, Fox and Partners, London)—design of bridges; L. F. La Cour (John Innes Institute, Norwich)—chromosome structure.

N. B. Marshall (British Museum (Natural History))—ichthyology; M. G. K. Menon (Tata Institute of Fundamental Research, Bombay)—K-mesons; R. Miledi (University College, London)—synaptic transmission; J. F. A. P. Miller (Walter and Eliza Hall Institute of Medical Research, Melbourne)—thymus and immunity; S. M. Partridge (Meat Research Institute, Bristol)—protein structure; J. S. Rowlinson (Imperial College, London)—thermodynamics of fluids.

A. E. Russell (British Aircraft Corporation, Bristol)—design of aircraft; F. G. Smith (University of Manchester)—magnetic field of the galaxy; R. W. Stewart (University of British Columbia, Vancouver)—boundary layers of ocean and atmosphere; J. B. Taylor (UKAEA's Culham Laboratory)—plasma physics; D. A. J. Tyrrell (MRC's Common Cold Unit, Salisbury)—the common cold; E. J. Underwood (University of Western Australia, Perth)—animal nutrition.

J. P. Wild (CSIRO, Sydney)—radio noise bursts from the Sun; C. G. Wynne (Imperial College, London)—optical instruments; V. C. Wynne-Edwards (University of Aberdeen)—ecology of birds.

KIDNEY PATIENTS

Demand for Machines and Organs

SOME two thousand five hundred kidney patients in England and Wales die each year because they cannot find places in renal dialysis units. In countries such as Sweden, most people who would benefit from dialysis receive it. Why not in Britain ?

Haemodialysis was first introduced as a routine treatment for kidney failure about five years ago, and there are now more than five hundred patients on dialysis in hospitals and nearly four hundred receiving dialysis at home (see page 1184). The Department of Health and Social Security (DHSS) says the chief difficulty in increasing these numbers is the shortage of trained staff needed to man the hospital units. According to Dr A. J. Wing of St Thomas's Hospital, London, the difficulty with home dialysis is the time taken by local authorities in making the necessary structural alterations to the houses, as well as the time needed to train patients in the use of their own units.

The cost of the treatment is also an important factor. The DHSS estimates that with twice-weekly dialysis, it costs about £2,000 a year to maintain a patient on dialysis in hospital, and £1,500 at his home. The capital costs of the electrical monitoring and fractionating equipment for each machine are between £1,500 and £2,000 and the widely used Kiil filters, in which the waste products are removed from the blood, cost about £400. Each filter has a life of about three years and in most hospitals is used by one patient only, so as to reduce the risks of transferring viral infections such as hepatitis. A safe but more expensive type of filter is a disposable parallel plate dialyser being marketed in Britain this month by the Swedish company Aga. Each filter costs £12 and is used for one dialysis only.

The existing dialysis centres were for the most part established by direct grants from the DHSS, but hospitals now have to find the money for maintaining and expanding their dialysis programmes from their block grants. In most hospitals, the emphasis at the moment seems to be on increasing the number of patients on home dialysis. Besides the psychological benefit, the advantages of home dialysis are its cheapness and the fact that patients can be dialysed more often. The DHSS seems to be cautiously encouraging the expansion of home dialysis programmes but unwilling to over-commit itself for fear that the increasing success of kidney transplantation as a form of treatment may in time make some of the expensive dialysis units redundant.

At present about 100 transplants are performed each year in Britain. A serious limitation is the number of donor kidneys available and this, according to Professor Shackman at Hammersmith Hospital, has arisen more from a lack of cooperation in the medical profession than reluctance on the part of the public to donate their kidneys. The other problem is to find the most suitable recipient for any kidney that does become available; a transplant is noticeably more successful the closer the tissue match between the donor and the recipient. Worldwide four-year survival rates, for example, are 94 per cent for live exchanges between matched siblings and 40 per cent between unmatched siblings; the latest two-year survival figures are 75 per cent using matched kidneys from unrelated dead donors, and 30 per cent with unmatched kidneys. Techniques for tissue typing have been steadily improving and now a total of twenty histocompatibility lymphocyte antigens have been identified and may be used for the purposes of matching. Kidneys are generally regarded as well matched if not more than two of these antigens differ between donor and recipient. Doctors at the London Hospital Transplant Immunology Centre estimate that a pool of 500 possible recipients is necessary to ensure that each donor kidney is well matched.

One way of organizing such a pool is for hospitals to cooperate in a computer network in which the tissue types and blood groups of all possible recipients are registered. Fourteen hospitals, mostly in London, are already involved in such a scheme and have a group of 120 patients waiting for transplants. In establishing such a system, another factor to be taken into account is the time needed to tissue-type and transport donor kidneys.

The question at the moment is whether there should be nation-wide cooperation along the lines of the London scheme, or whether, bearing in mind the problems of transport, a series of regional schemes would be preferable. The transplantation committee of the DHSS under the chairmanship of Sir Hedley Atkins, the former president of the Royal College of Surgeons, has been looking into this, and its recommendations are expected shortly.

Parliament in Britain

Kidney Machines

In January this year, 278 hospitals were equipped with kidney machines capable of treating a total of 509 patients and another 378 patients had installations in their homes. The exact number of people who require this type of treatment is not known. This information, which was given by Baroness Serota, Minister of State, Department of Health and Social Security, will, according to Lord Auckland, give only limited satisfaction because too few kidney machines are available in regional hospitals. Lord Auckland said that the large amount of regional development, and the growing numbers of people moving out of London, constitute a strong case for making more of these units available outside London. Baroness Serota replied that in 1965 there were only a handful of small renal dialysis research units, but in January this year there were thirty-one major units in England, six in Scotland, and one in Wales. Two more units have started work since then, five are being extended and three more are planned, she said.

Baroness Brooke of Ystradfellte also asked how many kidney machines are not being used because of a lack of trained manpower to look after them. Baroness Serota had, however, no figures either for the shortage of manpower or for the number of machines which are not being used. (Oral answers, Lords, March 17.)

Science Research Council

The alleged bias of the Science Research Council against Scotland has received the attention of Mr Ross, Secretary of State for Scotland, and Mr Short, Secretary of State for Education and Science. Mr Ross told Mrs Winifred Ewing that both ministers are concerned that Scottish interests are taken into account in questions of this kind, and that the number of Scottish academics on the Science Research Council boards has been increased from two to four. (Written answers, March 19.)

Uranium Supplies

Dr Ernest A. Davies, Joint Parliamentary Secretary, Ministry of Technology, said that the Atomic Energy Authority is confident that the intense exploration for uranium now being undertaken in many countries will result in sufficient uranium being available at reasonable prices for the UK programme. He also said that uranium reconnaissance in selected areas of the UK has been sponsored by the AEA, through the agency of the Institute of Geological Sciences. The latest programme began in March 1968 and is continuing. Mr Alexander Eadie had asked whether the Minister of Technology is satisfied that sufficient supplies of uranium will be available, in view of the shortage of indigenous resources envisaged by the European Economic Community. (Written answers, March 16.)

Nuclear Powered Ships

The government has no proposals at present for the production of a nuclear powered merchant ship, but representations from interested parties are still being studied, Dr Ernest Davies said in reply to questions from Mr Edwin Brooks. Dr Davies pointed out that although the situation has altered in a technical sense over the last few years, the chief concern is whether there would be a market for such vessels. (Written answers, March 16.)

Miscellaneous Intelligence

M. le secretaire perpetuel of the Royal Academy of Sciences, Letters and Arts of Belgium has announced that his functions as perpetual secretary came to a close at the end of last year.

The cyclamate farce has romped its way through many curious interludes, but what must surely be the last scene of all is the announcement that saccharin, too, is under suspicion of causing bladder tumours. The rats that got cyclamate banned, it will be remembered, were, of course, fed not with cyclamate but a combination of cyclamate and saccharin. With the unerring certainty of a water diviner, the United States Department of Health Education and Welfare spotted that the cyclamates were the villain of the pair and banned them forthwith. The ban was withdrawn in part but too late to save health authorities in other countries, such as Britain, from stampeding down the Gadarene slope. The belief that saccharin, too, is carcinogenic, voiced by G. Bryan of the University of Wisconsin in evidence to the United States Government, is all that was needed to complete the logical somersault into a Wonderland that even Alice never dreamed of.

Found in a junk-shop in Greenwich, London: a copy of *A Classification of Living Animals* by Lord Rothschild, inscribed by the author, "This is an exceedingly boring book". These modest words belie its opening sentence, "During my studies of spermatozoa, I have often been frustrated by having to consult a number of books. . . . " which, for a catalogue, has a rare sparkle.

An advertisement for American scientists to take up jobs in Britain would "attract about 10,000 replies", according to Mr Harry Hoff, the chairman of the selection board that tours North America on behalf of the Scientific Civil Service to recruit British scientists. If this is the epitaph of that ever-interesting topic, the brain drain, perhaps Mr Hoff's should be "Is his the face that lured ten thousand home, And spurned the topmost towers of IBM ?"

A hand-out from the United States Department of Commerce begins with the arresting words, "As civilization continues to contaminate the atmosphere. . . ." Were the ideals of the noble savage ever so succinctly, if unwittingly, expressed ? If the Department of Commerce continues to use words without thought, it cannot but hasten the return of the good old days when barbarism kept the Earth pure.

Also in the best Doomsday spirit is a press notice from the US Department of Commerce that begins with the arresting declaration: "Lightning, the biggest killer in nature's arsenal . . .".

A blatant invitation to spendthrifts is held out in a current issue of *Developmental Psychology* (**2**, 154; 1970). Dangled in a footnote to an article entitled "Birth Order and Avoidance of Dangerous Activities" is the insidious alternative, "An extended report of this study may be obtained without charge from (the author) or for a fee from the National Auxiliary Publication Service".

NEW WORLD

More Grumbling about Mansfield

SENATOR MANSFIELD has more to answer for as the days go by. The authorization hearing of the National Science Foundation in the House of Representatives finished last week (on March 19) with a recitation by four academic scientists of the ways in which useful projects would be harmed by the requirement that in future the Department of Defense must not support basic research unless this has "a direct or apparent relationship to a specific military function or operation". The fear that the National Science Foundation will not have the funds to take care of the projects dropped by the military departments—one speaker last week estimated that between $30 and $50 million extra would be needed—has been a constant theme in the hearings this year (see *Nature*, **225**, 785; 1970). This point has also been made in a special report to the subcommittee (*Mission Agency Support of Basic Research* dated February 25) by its Research Management Advisory Panel, a group of outside advisers. Everybody is clearly somewhat at a loss to know how the Administration has come to make such a muddle of the transfer of basic research from the military to the civil payroll. At least one member of Mr Daddario's subcommittee blames Congress as well. Representative Charles A. Mosher said at the hearings last week that "under the present arrangements, we cannot expect Congress to know its own mind. It's a sad indictment, I know, but it's the truth".

At several points last week, members of the subcommittee and their witnesses echoed each other's conviction that the implications of the new restriction on the research policy of the Department of Defense cannot have been fully appreciated when, last December, Senator Mansfield was able to attach Section 203 to the defence appropriation bill for the current financial year. Mr Daddario was concerned that the lack of a formal mechanism for the transfer of responsibilities for basic research from the military to civilian agencies might mean "a lost generation of scientific manpower". Dr Ivan L. Bennett, director of the New York University Medical Center and a member of the Research Management Advisory Panel, told the subcommittee last week that "for various reasons, it has not been possible within the executive branch to effect the transfer in a coordinated manner".

Dr Bennett provided a calculation of how much money would be needed for the National Science Foundation to be able to take over the projects that the Department of Defense had already dropped from its basic research programme. The reduction of the Department of Defense budget allocation for research in universities from $247 million in the current financial year to $215 million in that beginning in July this year implied, he said, that at least $32 million a year would be needed to keep the universities in a style to which the Department of Defense had accustomed them. But this calculation takes no account of the projects being dropped by other agencies—the University Sustaining Program which NASA is this year having to abandon. The total cost might be $50 million. Dr Bennett argued that the National Science Foundation is not provided in the new budget with enough money to take over these funds—Dr William McElroy has talked of an extra $10 million in the basic research programme for drop-out projects (see *Nature*, **225**, **785**; 1970). There is also the fear that the Department of Defense may be unable to defend all of its present budget for university research against Congressmen who are moved by the spirit of the Mansfield amendment in the defence authorization hearings now under way.

Some of the practical effects of the cuts which have already been made were described to the committee last week by Dr B. Lax, director of the Francis Bitter National Magnet Laboratory at MIT. The laboratory was set up in 1960, chiefly by the US Air Force, and is an outgrowth of the Lincoln Laboratories. Professor Lax described his laboratory as a unique facility which served not only as a mission-oriented research laboratory, chiefly in military electronics, but also as an academic laboratory used by more than 100 visiting scientists each year and contributing to teaching as well. Professor Lax explained that the financial pressures of the past few years had already forced the laboratory to trim its sails—the research staff has been reduced from 27 to 19. But "section 203 also declared the magnet programme irrelevant to the work of the Air Force" and, "we shall have to make very drastic cuts in the next few months".

The Magnet Laboratory has been trying to find support for some of its work from organizations like the National Institutes of Health, but "promising projects have run up against a brick wall". The result, Professor Lax said, is that the laboratory is now operating at one eighth of its full capacity. He was afraid of what will happen now that the laboratory could not count on being able to build the advanced equipment which it had designed. "Unless the National Science Foundation takes on the responsibility for the facility and supports our version of such an advanced project, we shall within two or three years relinquish the leadership we have worked so hard to attain."

The Haystack facility at MIT, which has contributed in important ways to radioastronomy in the United States, is also threatened by the impending cuts. Professor Lax said that "unless relatively modest support for this operation is found, this superb instrument will be irretrievably lost to the academic community". If the economy drive prevents the construction of new radio telescopes elsewhere, at least it should be possible to make the best use of the facilities which do exist. But MIT will also suffer from the way in which the research budget of NASA's Space Science Center at MIT, an interdisciplinary laboratory, has been "cut from $1,000,000 to zero in 1972".

Interdisciplinary laboratories are especially at risk in the present climate, according to Professor Lax, who pointed last week to the irony that these are the kinds of laboratories which need to be encouraged if science is to be applied successfully to social problems.

But academic science also stimulates industrial innovation and prosperity, and MIT has Route 128 around Boston to prove it. But "if this formula was so successful, why are we abandoning it ? . . . Science and technology are in retreat, not only in the universities but in industry and in the country as a whole".

The effects on the cuts on the balance between graduate and undergraduate education were the chief concern of Dr Charles L. Hosler, who also provided the most elaborate oratory last week. He said that the proportion of undergraduates staying on for graduate schools was already declining, even though it was more than ever clear that "much of our BS training has become superficial . . . and there is not enough time in the four-year program to give a student the breadth and depth that many of today's programs require". In Dr Hosler's experience BS graduates in the United States are now being diverted from the graduate schools by the attractive starting salaries which they are offered in industry. Like other speakers, he was anxious that there should be enough highly trained people "to solve tomorrow's unknown problems". For the benefit of those who are more directly concerned with simple profit and loss, he produced a calculation that the extra $100,000 which a PhD graduate could expect to earn in the course of his working life would yield an extra $20,000 in taxes, more than enough to pay for the cost of a graduate school stipend.

President Nixon's campaign statement that "scientific research cannot be turned off and on like a faucet" was thrown back last week by Dr Thomas Jones, president of the University of South Carolina, who feared that the effects of the Mansfield amendment would be especially severe for universities not in the first flight of academic research institutions. Surely the Federal Government, which some years ago was urging universities like his own to develop new graduate schools, now had a duty to continue to provide for them. In the event, at times like the present when institutions are competing for diminishing funds, "the ripples spread outwards as the prestigious institutions" shoulder aside their weaker fellows. One result had been that in the University of South Carolina, the amount of new research grant support for 1970 will be only a half that obtained in 1969.

Dr Davies also regretted the way in which the first report of the National Science Board, which in 1969 urged that graduate education should be accepted as a federal responsibility, "has received so little attention". He thought it essential that graduate education should be widely spread across the United States, with at least one strong centre of scientific research in every state. The alternative methods for financing graduate schools spelled out by the National Science Board deserved consideration.

The word "catastrophe" was used on several occasions during the session last week to describe the consequences of the impending shortage of money for basic research. Several witnesses urged that the rate at which grants are reduced should at least be matched to the time-scale of forward planning in the universities. The chairman of the subcommittee, Mr Daddario, said that arranging that universities could safely plan ahead is largely "an institutional problem". The season of talk about the creation of new agencies is evidently about to be reopened.

Consequences of Mansfield

THE report of the Research Management Advisory Panel (*Mission Agency Support of Basic Research*) is a brief but forceful document. "The colleges and universities of the United States are an essential national resource, central to stability, economic progress and security" and "the present science establishment of the United States is unique". But "most universities in the United States are experiencing severe financial strains which threaten their very existence as economically sound national resources in the sciences". Only the Federal Government can sustain academic science. "National policy has recognized the justification for Federal Government support of science for the past 25 years. At the heart of this crisis in our universities is academic science, both research and training. These are in jeopardy."

The report goes on to list the pressures on academic research—larger enrolments, increasingly expensive equipment and facilities, inflation, the development of interdisciplinary programmes and the involvement of scholars in several kinds of public service. Yet federal spending on academic science has not kept pace with inflation and "we enter the 1970s with a greater need for scientific knowledge but faltering support for scientific research".

The panel is alarmed because this trend threatens to undermine "our recently won leadership in science". . . . Government support for university research has become unstable and unpredictable. It is actually decreasing in several fields of science and is now inadequate in virtually all scientific disciplines. The Federal Government . . . is now treating university basic science as a luxury it can no longer afford . . . the always precarious balance of university financial needs and funding support for science is being destroyed. The universities must be, and are, willing to accept budget constraints, but "recent abrupt actions of the Federal Government have set arbitrary ceilings, cut appropriations for the National Science Foundation and redesignated the criteria under which Department of Defense appropriations may be spent. The results of these actions have been most serious. University administrators are unable to maintain coherent programs in the face of sudden changes in Government practice, for which there has been little warning".

The report goes on to say that the Mansfield amendment is "potentially disruptive" and urges that the "Federal Government carefully consider the disruption that an overly restrictive interpretation . . . would have on the close contacts of those who work in applied science and engineering". The panel also draws attention to the way in which the new developments put in hazard the "historic national policy that each mission department and agency which draws upon science in its operation should support its proper share of the country's research".

COMMUNICATIONS

Arrivederci Intelsat

WILL there be an international satellite treaty in 1970? Perhaps, perhaps not. The Intelsat conference to write a permanent agreement for the world's communications satellite network broke up on Friday in a brave and hopeful mood but without an agreement. It will have to meet again. The third of these huge unwieldy and expensive conferences had produced enough accord to provide about half a treaty.

The United States had finally agreed to let the organization which it had founded in 1964 be managed by an international directorate, rather than by the semi-public American company Comsat. And Zambia joined Intelsat. When an organization can recruit several new members—Yugoslavia was another—while it is still building itself, it cannot be too sickly.

There are some serious disputes still to be worked out before the full membership meets again. The small nations of Africa and the Middle East are passionate to have Intelsat governed by a powerful assembly in which the representatives of governments, not of telecommunications entities, would have a vote, one to a country, all countries equal. Needless to say, the Americans oppose this, but the smaller nations have the sympathy of the British and European bloc which believes that the assembly should be given teeth, even if it is prevented from biting. To sort out this and other contentious issues, Intelsat will set an intersessional committee to work. It will meet in May, possibly in Washington, possibly in Guatemala City. Yet even that decision is being subjected to a kind of small nation–big nation tug of war.

BUREAU OF STANDARDS

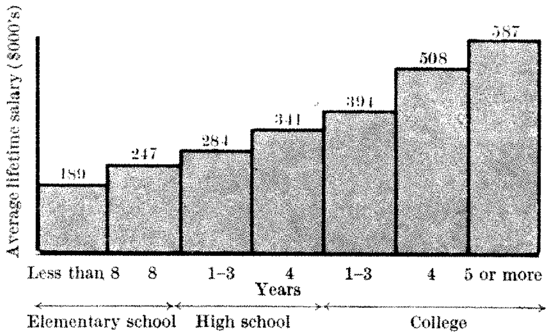
Boom and Diversity

THE National Bureau of Standards is one of the few scientific institutions in the United States which is clearly destined to grow in the next few years. It is also likely to find itself engaged in several new kinds of projects which, in time, are likely to bring about a shift of emphasis from the traditional preoccupations of standards laboratories with measurement, standardization and compilation to more general responsibilities for the technical aspects of consumer protection and the evolution of government policy towards industrial technology. The way in which the wind is blowing can be seen clearly enough in the annual report of the bureau for 1969, now published (US Government Printing Office, C13/1 : 325, $1.25). The changes which are afoot have the enthusiastic support of the director of the bureau since September 1969, Dr Lewis M. Branscomb.

Some of the bureau's new work, however welcome, has been thrust on it from outside. Thus the bureau has become the instrument in the United States for the development of technical standards of flammability of the kind necessary to provide protection for innocent consumers under the Flammable Fabrics Act. The bureau seems already to have identified the kinds of fabrics for which new standards will be needed, and is at work on the development of test methods and sampling techniques. Evidently it is going to become the fountainhead of wisdom in the regulation of flammability standards for the consumer market. In much the same spirit, the bureau has also been given responsibility for safety in the design of automobiles, and has in the past year been hard at work on the development not merely of standards of performance for tyres but on methods of conveying such information to the ultimate consumers. In the past few months, the bureau has also been given responsibility under the Fire Research and Safety Act for the development of methods of fire protection and of standards for making sure that these are properly applied, although at the spanking new headquarters at Gaithersburg, thirty miles into Maryland from Washington, there is a tinge of regret that on this occasion Congress has willed the ends but not the means.

The National Bureau of Standards is also now the organization responsible for making a technical study of the "advantages and disadvantages of increased use of the metric system in the United States". If there is ever to be a change to the SI system, the National Bureau of Standards will provide the starting point—and has already worked out rules for the use of SI units in its own scientific publications. The bureau's annual report says that the Metric Study is now confident of being able to provide "reasonable estimates" of the cost of a changeover to the metric system in several industries of the United States. The report says that the study is starting from the basis "of looking at potential costs as they would accrue if metric measurements were to be applied to new or redesigned products, stressing the concept of planning a transition . . . at an optimal rate, without going back and changing all the drawings that are in the files". This procedure is intended to avoid the "exaggerations and astronomical costs" which come from a "doctrinaire approach based on an all or nothing plunge into metric measures". The report goes on to explain that a changeover would be more practicable in industries where innovation is rapid than in those where equipment remains substantially unchanged for long periods of time, and cites the railroad and oilfield industries as ones in which "changes in existing equipment do not appear to be warranted". One of the jobs now under way is the development of a questionnaire for the collection of information about the needs of particular industries. On the face of things, at least, it looks a little as if the National Bureau of Standards, and the bodies such as the American National Standards Institute with which it is working closely, will recommend a kind of patchwork of standardization.

Money Value of Education



NEWS AND VIEWS

The Man who Lived with Australopithecines

An eminent archaeologist once divided early classical Greek sculpture into two periods, the type for the first period being a head in a museum at Berlin and the type for the second a torso in a museum in Athens. The two periods were quickly reunited when a diligent student spotted a similarity between the two type specimens, arranged for casts to be made, and found that the Berlin head fitted on to the Athenian torso. An equally serendipitous matching, though more constructive in its effects, has been made at the Transvaal Museum in Pretoria. Mr R. J. Clarke describes (this issue, page 1219) how he was sifting through the museum's rich collection of australopithecine material (*Paranthropus robustus*) from the Swartkrans site when he noticed that parts of a cranium seemed untypical. Remembering that one of the first investigators of the site, Dr J. T. Robinson, had argued for the existence of a second, more advanced, hominid at Swartkrans, Clarke immediately wondered if the cranium might have a bearing on Robinson's case. Unfortunately Robinson had managed to assemble only a handful of fragments that he considered to belong to the second hominid, but, looking them over, Clarke discovered that a piece of upper jaw fitted exactly with the suspect piece of cranium. The two fragments together tell far more than they did apart and enough of the newly reconstructed skull is present for Clarke and his colleagues to assign it to the genus *Homo*. This confirms Robinson's original supposition that Swartkrans was inhabited both by australopithecines (the descendants, on man's side of the line, of the common ancestor of men and apes) and by a form of early man. The discovery also greatly enhances the importance of the site.

Swartkrans urgently needs to be dated before it can figure prominently on palaeontologists' maps, and the article by Dr Mary Leakey (this issue, page 1222) provides the first real clue to its chronology. Despite the distance between Swartkrans and Olduvai, she finds a "suggestive similarity" between the stone industries of the two sites. If this is taken to imply that the two sites were roughly contemporary it would mean that Swartkrans was inhabited some 1·75 million years ago.

This and other straws in the wind suggest that the Swartkrans site may become of major significance for unravelling the evolution of man, particularly the transition between the two genera, *Australopithecus* and *Homo*, which are represented there. As Dr C. K. Brain described last week (*Nature*, **225**, 1112; 1970), excavations were begun at the site in 1948 but not resumed until five years ago. In the meantime a seam of limestone that had been uncovered in the cave was spotted by a miner whose activities left the site in a chaotic state. The site had also received the attention of lime miners in the 1930s who dumped some 200 tons of fossil bearing rock on the hillside below the cave. Several important fossils, including, for example, the two hominid vertebrae described by Dr Robinson (this issue, page 1217) come from the miners' rubble. Nevertheless, enough material has been left *in situ* to indicate the original form of the cave, on the basis of which Dr Brain has ingeniously inferred the existence of a second cave, now vanished because of the erosion of the hillside, from which detritus was funnelled down into the cave below.

If the Swartkrans site turns out to be as significant as the present reports suggest, the wheel will, in a sense, have come full circle. It was at the southern African site of Taung in Botswana that Professor Raymond Dart discovered the first australopithecine in the 1920s. The southern African sites were eclipsed by the discoveries in the late 1950s at Olduvai in Tanzania and more recently attention has shifted to the finds in the Omo Valley and other sites in East Africa. The southern African sites have now been pushed back into the palaeontological limelight, but whatever future surprises they may hold, none is likely to be more felicitous than Mr Clarke's matching of the two *Homo* fragments in the Transvaal museum and its vindication of the suggestion made by Dr Robinson more than 20 years ago.

DIFFERENTIATION

Sorting Cells Out

from our Cell Biology Correspondent

Recent advances in the cell biology of differentiation have been repeatedly held up by the lack of a means to fractionate a population of differentiating cells into sub-populations at different stages of differentiation. It is only necessary to recall how molecular separation techniques have transformed biochemistry to realize the potential of a reliable cell separation technique.

In the past ten years several separation techniques designed to exploit differences in cell density have been described, but none has found widespread application, no doubt because differences in cell density are small. Cells differ much more in size, however, and in the early 1960s Mel and his colleagues tried to use this difference as a basis of cell fractionation. Their so-called STAFLO system was designed to separate cells by their sedimentation velocity through gradients under the Earth's gravitational field. But the method was bedevilled by wall effects and other flow phenomena which reduced its usefulness.

In 1967 Peterson and Evans (*Nature*, **214**, 824) described an improved sedimentation velocity apparatus which they used to fractionate bone marrow cells, but little use seems to have been made of the technique until it was taken up recently by two groups in Toronto, at the University and the Ontario Cancer Institute. These groups seem to have provided a widely applicable and easily assembled apparatus for the biologically meaningful separation of various differentiating cell populations.

Last year Miller and Phillips (*J. Cell. Physiol.*, **73**, 191; 1969) described the theory behind 1 g velocity sedimentation and showed how to make their STAPUT apparatus. They were then using it to separate a wide range of differentiating cell populations, including haemopoietic stem cells and antibody forming cells. Now the first full accounts of examples of cell separation on STAPUT gradients are appearing in print. Worton, McCulloch and Till (*J. Cell. Physiol.*, **74**, 171; 1970), for example, report the separation of two types of haemopoietic cells, which are capable of forming colonies in tissue culture, from a suspension of mouse bone marrow. McCool *et al.* (*Cell Tissue Kinet.*, **3**, 55; 1970) have separated populations of erythropoietin-sensitive cells from haemoglobin synthesizing cells in rat bone marrow. And in the latest issue of *Proceedings of the US National Academy of Science* (**65**, 192; 1970) Lam, Furrer and Bruce describe the fractionation of mouse spermatogonial cells into seven distinct populations with biologically different properties. These populations represent cells at the various stages of spermatogenesis, and by labelling the mice with tritiated thymidine before making the separation, Lam *et al.* have been able to follow some of the kinetics of the process. The fact that spermatids are separated into two fractions, early and late, both distinct from the mature spermatozoa fraction, gives some idea of the impressive resolving power of velocity sedimentation. The implications of the technique for cell biology are hard to overestimate. No doubt glass blowers in countless laboratories will be summoned hastily to assemble the Miller and Phillips apparatus in the next few months if they have not already done so.

NUCLEIC ACID

DNA in New Guises

from our Molecular Biology Correspondent

THERE is more to DNA than meets the spectrophotometer. The remarkable complexity of morphological forms found in different systems has provided a rich pasture in which a small herd of physically minded molecular biologists have browsed to no little effect. An interesting new study by Lee, Davis and Davidson (*J. Mol. Biol.*, **48**, 1; 1970) concerns the DNA of phage particles induced in certain strains of *E. coli* that are host to a prophage. The phage DNA is linear before lysis, but becomes circular on maturation, and the contour length of DNA round the circles is less by 7·5 per cent than that of the linear helices. This suggested to Lee *et al.* the presence of a previously recognized phenomenon, that of sequence repetition at the ends of the chains. This leads to certain well defined consequences if the strands of the linear DNA are separated and then allowed to renature. Because the chains terminate at various points in the repeating sequence, annealing of the mixture must lead to populations of double helices with loose single stranded ends of varying lengths. If these tails at opposite ends of the duplex are long enough, they will contain mutually complementary lengths of bases; the molecules can therefore maximize the degree of base-pairing by cyclizing to allow the ends to pair as far as they are capable. One will therefore hope to see in the electron microscope circles, containing some residual unpaired ends, where the chains terminate, and these are indeed observed as small brush-like formations at varyingly separated points on the circles.

It is possible to derive the length of the repeated terminal sequences with extraordinary precision with the electron microscope in conditions leading to extension of the single strands, using samples of φX 174 DNA on the same grid as a length standard. The lengths of the ends projecting from the circles measured in this way come out gratifyingly to 7·4 per cent. This value, however, represents an appreciable spread, thought to correspond to a real heterogeneity of length in the repeating ends. A related phenomenon that Lee *et al.* have uncovered is referred to as branch migration, and consists in the displacement of a paired end of a chain by the unpaired loose end abutting on it, which has the same sequence. In some cases, therefore, both chain ends have short loose ends emanating from the point on the duplex at which they meet, and this gives the appearance of a fork. All the indications are that the beginnings of the chains are randomly distributed around the chromosome.

The effect of intercalation of a dye, ethidium bromide, on the supercoiling of circular DNA was studied by Vinograd and his associates. They demonstrated that the insertion of the dye, which causes a change in the pitch of the primary duplex and therefore generates some slack in the chain, changes the number of turns in the supercoil in a predictable manner. Bauer and Vinograd (*J. Mol. Biol.*, **47**, 419; 1970) now show how the phenomenon can be used to derive the energetics of the supercoiling process. From the binding isotherms for the dye it is found that if the DNA is intact (though not if it contains a single-strand break) the binding free energy varies steeply with the degree of saturation. Intercalation in an "overwound" helix allows the strain to be released. As the pitch increases beyond the point at which the supercoil is fully undone, the DNA has to supercoil in the opposite sense to take up the further slack that is generated by the intercalation of more dye, and binding therefore becomes progressively less favourable. From the statistical mechanics of such a model a free energy for the supercoiling process can be extracted. This turns out to be 18 calories/base pair, and this energy can be used to assist a process such as dye intercalation which unwinds the superhelix, and must in turn be supplied if the superhelix is to be wound tighter. One of the consequences of this energy of destabilization is a diminution in the melting temperature, compared with linear DNA (or circular DNA with a single-strand break). When a few base pairs have melted and more slack is again introduced the strain vanishes, and so does the difference in melting temperature. This accounts for the asymmetrical melting curves observed in supercoiled samples.

A different case of asymmetrical melting occurs in mitochondrial DNA from several strains of yeast (Bernardi *et al.*, *J. Mol. Biol.*, **48**, 23; 1970). The mitochondrial species, by dint of new preparative methods introduced by Bernardi, are now, by comparison with earlier times, made by the hogshead; that is to say, sufficient for spectroscopic and chemical studies. The DNAs contain from 83 to 87 per cent of (A+T), which is remarkable enough in itself. In addition, the shape of the melting curves shows that there is strong compositional polarization in the chains. These curious mitochondrial DNA species are evidently to be correlated with the observed cytoplasmic mutations.

NUCLEOSIDES

Syn Expected and Unexpected

from our Biomolecular Structure Correspondent

Anti and *syn* denote the two stereochemically preferred ranges in the orientation about the covalent bond linking sugar and base in nucleosides. Most nucleosides and nucleotides crystallize with the *anti* conformation, and this is also the conformation in the DNA double helix. But the observation by Travale and Sobell (*J. Mol. Biol.*, **48**, 109; 1970) that 8-bromoadenosine and 8-bromoguanosine crystallize in the *syn* conformation is by no means unexpected, for even a crude analysis with space-filling models shows considerably more steric-hindrance between the bromine atom and the sugar for the *anti* range than for the *syn*. A much more unexpected member of the select group of nucleosides and nucleotides which crystallize in *syn* (and the only pyrimidine) is 4-thiouridine (Saenger and Scheit, *Angew. Chemie*, **8**, 139; 1969).

Uridine itself and its 5-substituted derivatives all crystallize with the *anti* conformation and the peculiarity of 4-thiouridine must be attributed to intermolecular interactions, suggesting that although there may be a considerable energy barrier between the *syn* and *anti* ranges their conformational energies are not very different. Several workers have suggested that the conformation about the glycosidic link is correlated with the pucker of the sugar ring. The sugar ring is most frequently puckered with C2 and C3 about 0·5 Å out of the best plane through the other four atoms of the ring. C2 endo indicates that C2 is out of plane on the C5 side of the sugar ring and C2 exo that it is out of plane on the O1 side and similarly C3 endo and C3 exo. Lakshminarayanan and Sasisekharan (*Biopolymers*, **8**, 475; 1969) have calculated conformational energies for purine and pyrimidine nucleosides with all four idealized sugar puckers as a function of the orientation about the sugar-base bond. They conclude that for pyrimidines with a C2 endo sugar there is an energy minimum in the *syn* angular range of comparable energy to that in the *anti* range. Although the sugar conformation in 4-thiouridine approximates to C2 endo, the observed orientation about the sugar-base bond is some 30° outside the allowed range proposed by Lakshminarayanan and Sasisekharan. This is not a serious discrepancy and can be attributed to the pucker in this structure departing from the idealized C2 endo, but it emphasizes that preferred orientations predicted from such calculations should be treated with caution.

As in deoxyguanosine (which also has the *syn* configuration), 8-bromoadenosine and 8-bromoguanosine have an intramolecular hydrogen bond between the 5′OH of the sugar and the base N3. This is the only type of intramolecular bond which has been observed in a nucleoside or nucleotide crystal from a sugar hydroxyl to either a base or a phosphate atom. Intramolecular hydrogen bonds from the 2′OH to N3 purine, O2 pyrimidine and to a phosphate oxygen have been proposed to account for observations in solution but have never been observed in the crystal.

The observation of the *syn* conformation for 4-thiouridine is of considerable interest, particularly because Scheit and Gaerter (*Biochim. Biophys. Acta*, **182**, 10; 1969) have evidence that in solution both the monomer and single stranded homopolymer assume the *anti* conformation. One of the chief stimulants to studying 4-thiouridine was its occurrence in transfer RNA and no doubt the army of model builders addicted to this molecule will be taking a new look at their creations. But it is hard to escape from the fact that the significance of the *syn* conformation in 4-thiouridine is for pyrimidine structures as a whole, which have hitherto been almost universally assumed to have the *anti* conformation in polynucleotides.

CELL CULTURES

Stable Haploid Line

from our Cell Biology Correspondent

THE fusion of plant cell protoplasts, reported a fortnight ago (*Nature*, **225**, 1016; 1970), raises none of the alarums which have come to surround similar experiments with animal cells. The next step, fusing a plant cell with an animal cell, is another story, however. Imagine the evening papers emblazoned with "Human Cabbages" or "Bacon with the Beans" and science fiction writers will have a field day populating planets with green men for whom a sunbathe is an epicurean treat.

Mercifully all that is still in the future, although the day when plant and animal cells are fused may not be so very distant to judge from the rate at which somatic cell genetics progresses. Freed and Mezger-Freed, for example, have recently isolated two stable haploid cell lines which point the way to analysis of recessive mutants (*Proc. US Nat. Acad. Sci.*, **65**, 337; 1970). These two lines arose in cultures of explants from haploid androgenetic embryos of *Rana pipiens* obtained by removing the female nucleus from the fertilized frog's eggs. For more than fifty subcultures, or at least 150 mitotic generations, these haploid cells have outgrown diploid variants, which, arising by endomitosis or cell fusion, usually overgrow haploid cells. Presumably on rare occasions, as a result of segregation, the frog sperm nucleus contains in a haploid karyotype all the genes necessary for vigorous growth in culture. Of course Freed and Mezger-Freed cannot rule out the possibility that duplications of small but crucial regions of the genome have occurred to account for the stability of their two lines, but such duplications cannot involve much of the genome. The haploid lines have almost exactly half the DNA of diploid cells, half the volume of diploid cells and the haploid chromosome number in 85 per cent of the cells in one line and 95 per cent in the other. There are, however, small but significant differences in the length of the chromosomes of the haploid cell lines compared with the standard karyotype.

Once auxotrophic mutants have been isolated, and this is apparently under way, it should be possible to exploit these two lines for mapping both dominant and recessive mutations, but the really important consequence of this work lies in the stimulus it should give to attempts to isolate haploid lines of mammalian cells. Apart from the strain of *Xenopus* that lacks nucleoli, amphibian genetics is undistinguished. What is needed is a haploid cell line from a mammalian species, such as the mouse, the genetics of which has already been worked out in some detail. The problem, of course, is to obtain a large enough population of haploid mammalian cells to give some hope of finding one cell with a genetic constitution compatible with growth in culture. One approach, being tried at Oxford, is to grow a haploid mouse embryo, but it may be technically much simpler to isolate a population of spermatids by velocity sedimentation (see page 1188) or some other cell separation technique and, with luck, establish a haploid cell line from them.

CHROMOSOMES

Chromosomes Manipulated

from our Cytogenetics Correspondent

TECHNIQUES for manipulating and changing chromosomes within living cells could provide somatic cell geneticists with more useful tools, if recent achievements with microneedles and laser beams live up to their promise.

In 1967, R. B. Nicklas and his colleagues manipulated chromosomes in living spermatocytes of the grasshopper *Melanoplus* with the aim of elucidating how they become exactly divided at mesons. Nicklas (*Chromosoma*, **21**, 1, 17; 1967) introduced a fine glass needle into the cell and pushed and pulled the chromosomes into new positions. He found that the bivalents were firmly attached to the spindle apparatus by their kinetochores; but they could be detached and then reattached to the spindle in a new orientation. The bivalent then segregated normally and the cell divided, but the resulting nuclei contained different chromosomes than would have been the case without manipulation.

Nicklas could also make bivalents behave in unusual ways. Both halves of a bivalent could be attracted to the same pole of the spindle if the kinetochores were suitably orientated by manipulation. Such a bivalent would always revert to a normal orientation, however. It seemed that bivalents with both kinetochores orientated towards the same pole (unipolar orientation) underwent reorientation because the forces of tension between bivalent and spindle necessary for a stable metaphase configuration in some way were not satisfied. To test this, Nicklas and Koch (*J. Cell Biol.*, **43**, 40; 1969) induced unipolar orientation in a metaphase bivalent, and then applied a force from a microneedle in the opposite direction to the poleward pull of the spindle fibres running to both kinetochores. Such bivalents under tension never reorientated; they only did so when the source of tension was removed. Thus it seems that a state of tension between the bivalent and spindle is required for a stable bivalent orientation that leads to orderly segregation.

Henderson and Koch have extended this observation recently (*Chromosoma*, **29**, 207; 1970). They induced two unipolar bivalents and caused them to interlock through micromanipulation, so that each exerted a force on the other. As expected, such a configuration was stable; it also resulted in the non-disjunction of both pairs of half bivalents. Such a manipulation allows the cell to bring about its own feat of genetic engineering without further intervention from the experimenter.

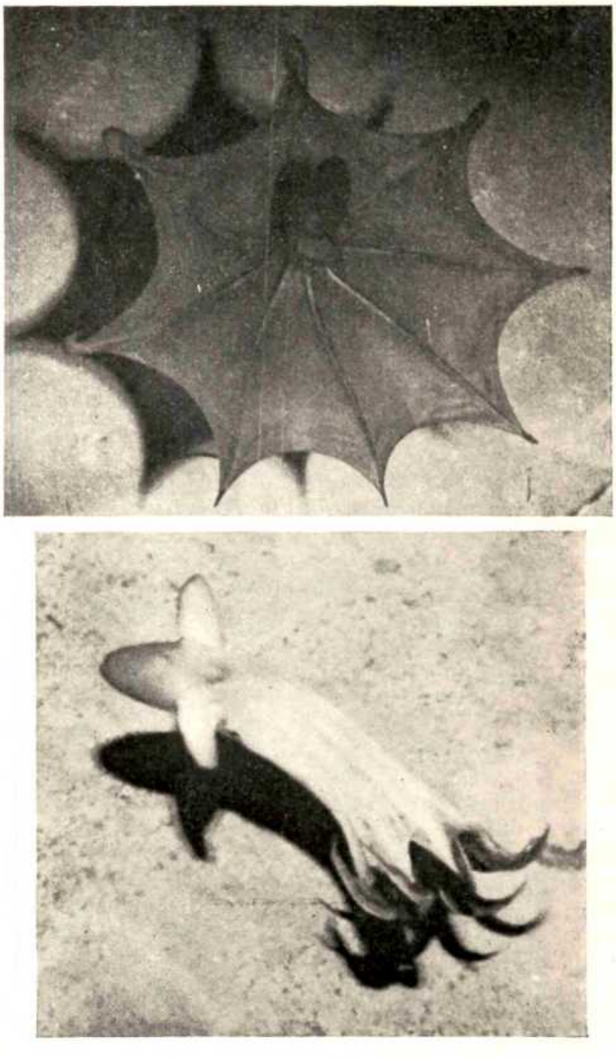
Other attempts at tinkering with chromosomes have been described by Berns and Rounds (*Sci. Amer.*, **222**, 98; 1970). Using laser beams they have been able to change, or destroy at will, segments of chromosomes in living dividing cells of salamander. One of their experiments was to destroy the secondary constriction in metaphase chromosomes—as might be expected, the daughter cells in the following interphase lacked a nucleolus. The laser beam can also remove pieces of chromosome.

This form of chromosome surgery, together with the other techniques for manipulation, would seem to offer considerable scope for influencing the structure and behaviour of genomes in somatic cells.

MARINE BIOLOGY

Strange Creatures of the Deep

THE objects in the photograph are not the open and closed version of an umbrella but deep sea octopods found at a depth of 13,000 feet off St Croix in the Virgin Islands. Scientists from the Naval Research Laboratory, Washington, photographed the creatures with a "fish", a versatile box of underwater cameras



and electronic devices, which has already helped to search for lost hydrogen bombs and the nuclear submarine Alvin. According to Dr Clyde F. E. Roper of the Division of Mollusks of the Smithsonian Institution, the creatures belong to the little known sub-order Cirrata. Further identification to family and even genus may be possible on the basis of the pictures.

INVERTEBRATES

Self Assembly of Cuticle

from our Insect Physiology Correspondent

MUCH has been learnt recently about the basic architecture of the fibrous cuticle of insects, notably by A. C. Neville and his colleagues (*Tissue and Cell*, **1**, 183, 355, 689; 1969), from the diversity in form of the pore canals. From this can be deduced the arrangement of the structural fibres of the cuticle which could not themselves be resolved.

In the layers of locust cuticle deposited during the day the microfibrils are all orientated in a preferred direction and so the pore canals run a straight vertical course through the cuticle in the form of untwisted ribbons. On the other hand, cuticle laid down during the night is lamellate: the microfibrils follow a helicoidal course changing direction 180° across the thickness of each lamella. This change in direction is imposed on the pore canals, which are then shaped like regularly twisted ribbons. They are not themselves helicoidal, as has been commonly believed. It has been known for more than a century that in Coleoptera and Hemiptera the direction of the fibre bundles in the cuticle changes 60° or 90° from one thick layer to the next. This transition has now been shown to be effected by means of a very narrow helicoidal zone of "lamellate cuticle".

Neville and Caveney (*Biol. Rev.*, **44**, 531; 1969) have applied this knowledge in a study of certain Scarabaeid beetles in which the metallic colours of the elytra are associated with the property of reflecting circularly polarized light in a manner precisely analogous to cholesteric liquid crystals. (This analogy has been pointed out particularly by Conmar Robinson, who demonstrated the same effect with systems formed from synthetic polypeptides.) Neville and Caveney have found evidence that these special interference colours in Scarabaeid beetles are determined by the helicoidal pitch of the microfibrils of the outer layers of the cuticle. The colours follow a bilaterally symmetrical pattern; but the sense of helicoidal rotation is the same all over the beetle, and is therefore bilaterally asymmetrical.

Thus the helicoid pitch seems to be under local control by the epidermal cells which secrete the cuticle; whereas the sense of rotation is presumably determined by the extracellular self-assembly or crystallization of an asymmetrical unit, comparable with the self-assembly of DNA, RNA, synthetic polypeptides and cholesterol derivatives to form helicoidal systems. Curiously enough, this system, by which asymmetrical units condense to form helicoidal microfibrils, seems to be the primitive system; it alone is found in the cuticle of the primitive Apterygota. The system with a preferred orientation, giving non-lamellate cuticle, is the more sophisticated since it requires specialized direction control by the cells. The microfibrils of the cuticle consist of protein and chitin; it is presumed to be the protein component that regulates the self-assembly into cholesteric liquid crystals, but the chemistry of the process is not known.

CANCER

Spread through the Body

from our Medical Biochemistry Correspondent

THE way that tumour cells can spread and produce tumours in other parts of the body—a process known as metastasis—is one of the most peculiar and dangerous aspects of cancer. Some recent work with heparin has shown that the progress of metastasis can be affected by changes in the surface charge of the cells. The effect of heparin on the production of metastasis was thought to be related only to its anticoagulant properties. But B. Hagmar and K. Noorby (*Intern. J. Cancer*, **5**, 72; 1970) have shown that in the concentrations normally used it interacts *in vitro* with cancer cells, and that its *in vivo* effects may sometimes result from interaction with the cell surface.

There was a small but significant reduction in the diameter of cells of the tumour MCG1-SS in suspension when they were incubated with heparin. The formation of aggregates and the viability of the cells were unaffected. There were fewer metastases in the lungs than in other parts of the body when animals received heparin before intravenous injection of tumour cells, probably due to anticoagulation effects. When cells were mixed with heparin and then injected, however, there was a significant increase in the number of metastases in the lungs, but a significant decrease in the volume of each new growth, so that the total volume of tumour in the lungs was reduced. There was also a considerable reduction in the volume of metastases in the liver.

The difference in behaviour when heparin is allowed to interact with cells before injection is probably due to effects on the electrical character of the cell surface, for chondroitin sulphate, another polyanion like heparin, had similar though smaller effects, while the polycation protamine had the opposite effect. Thus one of the factors influencing the spread of tumours and size of secondary tumours, at least for cells of this type, is the surface charge on the cell. Methods of modifying the charge might therefore reduce the spread of cancer.

In some conditions many tumours arise very quickly, and it is not always possible to tell whether the process involves several primary tumours or metastasis. Analysis of enzyme variants has shown that some multifocal tumours are derived from a single clone, while others have arisen from more than one cell and are presumably due to malignant change in several cells.

Recently Fialkow *et al.* have looked at the glucose 6-phosphate dehydrogenase isoenzymes in seven patients with Burkitt's lymphoma, who were heterozygous for this enzyme (*Lancet*, i, 384; 1970). Electrophoresis revealed two bands of activity in all normal tissues. Samples from twelve different tumours, however, all contained but one variant of glucose 6-phosphate dehydrogenase. Fialkow *et al.* point out that their results do not necessarily mean that all these tumours are caused by malignant transformations of a single cell. Nevertheless, one clone of cells does seem to become dominant in each tumour, which must be explained for an understanding of this condition.

VACCINES

Polysaccharides against Bacteria

from a Correspondent

A POLYSACCHARIDE vaccine has been used recently for successful immunization of soldiers against meningococcal disease. Polysaccharide antigens are found in many bacterial species; their ability to stimulate antibodies in man and animals is variable and has provided an abundance of problems related to animal species, dose and physical and chemical characteristics (E. A. Kabat and M. M. Mayer, *Experimental Immunochemistry*, second edition, Thomas, Springfield, Illinois, 1964). Last year the group-specific polysaccharides of *Neisseria meningitidis* were isolated by a new method (E. C. Gotschlich, T. Y. Liu and M. S. Artenstein, *J. Exp. Med.*, **129**, 1349; 1969) using the cationic detergent 'Cetavlon' to precipitate the polysaccharides from the whole bacterial culture.

The principal constituent of the group A polysaccharide is N-acetyl, O-acetyl mannosamine phosphate; the group B polysaccharide consists primarily of N-acetyl neuraminic acid; the group C polysaccharide contains N-acetyl, O-acetyl neuraminic acid. Meningococcal polysaccharides prepared in this way have a molecular weight of more than 100,000, which probably accounts for their immunogenicity in man. Antibodies produced by injection of 50 μg of polysaccharide can be measured by passive haemagglutination, immunofluorescence and bactericidal tests (E. C. Gotschlich, I. Goldschneider and M. S. Artenstein, *J. Exp. Med.*, **129**, 1367; 1969). Opsonic antibodies are also produced (R. Roberts, *J. Exp. Med.*, **131**, 1970). These polysaccharides stimulate antibodies of the three major immunoglobulin classes, although the bactericidal activity resides in the IGG moiety alone. Antibodies which develop after immunization with the A or C polysaccharides are group specific, as is the protection against meningococcal disease which is conferred by polysaccharide vaccination (M. S. Artenstein, R. Gold, J. Zimmerly, F. A. Wyle, H. Schneider and C. Harkins, *New Engl. J. Med.*, **282**, 417; 1970). Artenstein *et al.* have administered a group C polysaccharide vaccine to military recruits and obtained an 87 per cent reduction in disease caused by group C meningococci, although disease caused by group B organisms was not prevented.

The specificity of the antibody induced by polysaccharide immunization is different from the antibody response to natural infection. After systemic or local nasopharyngeal infection with meningococci, bactericidal antibodies with heterologous activity can be detected as well as antipolysaccharide antibodies (Goldschneider, Gotschlich and Artenstein, *J. Exp. Med.*, **129**, 1327; 1969). In addition to humoral antibodies and immunity, administration of group C meningococcal polysaccharide to humans induces a local nasopharyngeal immunity to the group C meningococcal carrier state (Gotschlich, Goldschneider and Artenstein, *J. Exp. Med.*, **129**, 1385; 1969). The mechanism of this local resistance has not been established so far.

CRYSTALLOGRAPHY

International Discrepancy

from a Correspondent

X-RAY intensity measurements have been carried out with single crystal diffractometers on crystals of the same compound in sixteen laboratories throughout the world. The occasion was the Single Crystal Intensity Measurement Project promoted by the International Union of Crystallography to determine the quality of X-ray structure determination. The sets of intensities were subjected to exhaustive statistical analysis followed by individual least squares structure refinements, and further comparisons of the results of the refinements. The first results have been published by S. C. Abrahams, W. C. Hamilton and A. McL. Mathieson (*Acta Cryst.*, **A26**, 1, 18; 1970).

A low-symmetry, low-absorption organic material was considered most suitable for the project, and so each participant was supplied with about twelve crystals of D(+)-tartaric acid, all from the same batch. The spacegroup is $P2_1$, which is non-centrosymmetric and monoclinic, commonly adopted by organic molecules. Each participant measured all $hk0$ reflexions including equivalent reflexions and all other reflexions with positive k and l out to $\sin\theta/\lambda = 0{\cdot}5$ Å^{-1}, using their normal procedures. Of the seventeen participants, one used neutrons and was not considered in the study, and one submitted two sets of data, believing the first to be liable to error, although the second was actually worse than the first.

At first the results appear profoundly disturbing. Although internal comparison of equivalent $hk0$ reflexions for each experiment revealed mean internal disagreements of less than 1 per cent for seven experiments and greater than 3 per cent for only two at 4 per cent and 5·5 per cent, inter-experimental comparison showed that mean deviations for the all-experiment average values of the intensities ranged between 3 per cent and 9·5 per cent for fifteen experiments, with two outliers having 14 per cent and 48 per cent disagreement. Yet both these outliers had shown quite acceptable internal disagreements of 1 per cent and 1·9 per cent respectively. These two sets of poor data were produced by machines of the equi-inclination type.

A careful analysis of variance was carried out in terms of the Miller indices h, k and l, the angular range in which the reflexion was observed, d^*, and the intensity of the reflexion. This analysis showed a larger range among the slopes of the interaction effects (indicating greater systematic trends) for the angular variables h, k, l and d^* for the equi-inclination diffractometers than for the four-circle diffractometers. The slight trends with intensity for experiments using CuKα radiation were opposite to those with MoKα radiation.

The first conclusion was that the results were more mutually concordant for four-circle diffractometers in which the crystal was rotated about three mutually perpendicular axes, while the detector was rotated co-axially with one of the crystal rotation axes—a mode of operation which can be likened to the generation of a stereogram—than for the equi-inclination devices with geometry analogous to that of traditional cylindrical crystallographic cameras. Second, the absolute accuracy of any set of data is at best 5–6 per cent, but may be as bad as 50 per cent with no internal evidence of malfunction. But, on the basis of an analysis of these results and experience with an equi-inclination machine, it seems that the two outstandingly poor sets of data are the result of an alignment problem peculiar to equi-inclination devices when mounting any triclinic crystal, or a monoclinic crystal to rotate about the *a* or *c* axes, as was the case here. This problem does not arise for monoclinic crystals mounted about the *b* axes or for any higher class of crystal.

The results of the individual structure refinements with these sets of data, however, are comforting. The poorer sets of data either failed to refine properly or else produced satisfactory coordinates. Indeed, the worst example which had shown 48 per cent average disagreement refined to a residual R of 4·7 per cent (R is the average disagreement between the observed and calculated structure factor amplitudes) which was the fourth best, with quite satisfactory coordinates. However, the anisotropic temperature factors (β_{ij}), which are related to the direction and magnitude of vibration of the atoms, were very poor indeed for the suspect data sets. For the worst set of data the value of $\beta33$, which is directly related to the amplitude squared of vibration in the *c* axes direction, was about four times the most likely value. The divergence of the thermal parameters was otherwise greatest when absorption corrections had not been applied.

The first lesson for non-crystallographers is that the coordinates of any X-ray structure determination can safely be accepted, but the quoted internally derived standard deviations should be doubled, unless precautions have been taken to improve the accuracy, in which case a factor of $\sqrt{2}$ is more appropriate. The second lesson is that the thermal vibration parameters should be regarded with suspicion, especially if absorption corrections were not applied, and the quoted standard deviations multiplied by a factor of about 5. For any structure which shows one or two of the axial vibration components (β_{ii} and U_{ii}) to be consistently large or small for all atoms, the cross terms (β_{ij} or U_{ij} where $i \neq j$), which determine the angles between the thermal vibration ellipsoid axes and the crystal axes, are probably meaningless, though the other axial components may be acceptable.

MOON

Latest Report from Houston

by our Astronomy Correspondent

PRELIMINARY examination of the Apollo 12 samples at Houston is now complete, and it is clear that there are some significant differences from the Apollo 11 material (*Science*, **167**, 1325; 1970). The reason in most cases is that the Apollo 12 site in Oceanus Procellarum is younger than Mare Tranquillitatis, and the most interesting observation singled out from the Apollo 12 report by the preliminary examination team is the K–Ar age. Once again this indicates that the maria are very old, but that with crystallization occurring about $2 \cdot 3 \times 10^9$ years ago the material of Oceanus Procellarum is roughly 10^9 years younger than Mare Tranquillitatis.

Other facts also point to the Apollo 12 site being less mature than that of Apollo 11, indicating that maria formation lasted at least 10^9 years. The surface layer of fragmented material, for example, is thinner than at the Apollo 11 site, and craters as shallow as 3 metres seem to have penetrated to the harder rock below. And the lower content of gases from the solar wind in the Apollo 12 dust indicates that the material has not been exposed quite as long as the Apollo 11 material.

The landing site in Oceanus Procellarum is on one of the broad rays centred on Copernicus, and the astronauts reported several areas of dust which is lighter grey than normal. Whether the dust which troubled the Apollo 12 astronauts more than expected during landing was due to a difference in soil mechanics between the two maria, or to a difference in Sun angle or in descent path, is not known yet. But the most important clues to the history of the dust layer are the core samples. One tube reached a depth of 70 cm—compared with 15 cm for the Apollo 11 tubes, although a different bit probably helped—and contains ten identifiable layers representing presumably different ejecta blankets. This is backed up by a sample of what looks like volcanic ash taken from a 20 cm deep trench excavated by the astronauts. Coupled with the different distribution of particle types in the dust from Oceanus Procellarum, it is clear that the dust layer does not have a uniform composition from mare to mare.

Although the rocks are similar to the finds in Mare Tranquillitatis, there are some notable differences. Fewer breccias were picked up, thought to be due once again to the thinner surface layer so that excavated material is more likely to be bedrock than to be formed from the stressing and hardening of surface material into breccias. The chemical indications are indeed that the Apollo 12 breccias were formed from fine material with a lower content of solar wind gases than the present dust layer. It is odd that the Apollo 12 rocks have a wider range of texture and composition than expected from the Apollo 11 mission, but the preliminary examination team say that the rocks are consistent with a fractional crystallization sequence, so that they seem to come from a single intrusive sequence or from several similar sequences.

GALAXIES

Rotation of Andromeda Nebula

from our Observatories Correspondent

IN many respects it is easier to study the rotation of the Andromeda Nebula (M31) than that of the galaxy. The Sun's situation in the dust clouds of the Milky Way makes it impossible to take optical measurements of the Doppler shifts of distant stars. This is why the rotation of the galaxy has been studied most often through the Doppler shift of the 21 cm line of neutral hydrogen.

This approach has the advantage that the neutral hydrogen gas clouds might be expected to be moving in circular orbits about the centre of the galaxy. Its principal disadvantage is that it is only possible to make indirect inferences about the distance of a cloud having a given Doppler shift. For these reasons the rotation curve of the galaxy—the run of rotational velocity with radius—is imperfectly known for the galaxy. This is particularly true for the regions close to the galactic centre and outside the Sun's radius (about 10 kiloparsecs). The total mass of the galaxy depends on the way in which the rotation curve behaves at large distances from the centre while the mass distribution with radius near the centre depends on the detailed behaviour of the rotation curve. Consequently both these quantities are poorly known for the galaxy.

The Andromeda Nebula is important because it resembles our galaxy, because it subtends a large angle in the sky, and because radial distances can easily be measured. M31 has been studied using optical techniques and the 21 cm line. For such a distant object the optical methods have an advantage because the angular resolving power of radio telescopes is low. Individual stars in M31 are faint and so the Doppler shifts of HII regions—bright clouds of ionized gas around young hot stars—are measured. Vera Rubin and Kent Ford of the Department of Terrestrial Magnetism of the Carnegie Institute of Washington have recently made a detailed study of the rotation curve of M31 (*Astrophys. J.*, **159**, 379; 1970). Kent Ford has been one of the pioneers of the application of image tubes to astronomical spectroscopy.

The gain in speed of the image tube over photography has enabled them to determine the Doppler shifts of 67 HII regions between 3 and 24 kpc from the centre of M31 with an accuracy of ± 10 km/s^{-1}. These emission regions were mapped several years ago by Arp and Baade. Inside 3 kpc there are no individual HII regions but instead there is a diffuse background of emitting gas. Rubin and Ford have used this to define the rotation curve inside 3 kpc.

Ford and Rubin's rotation curve for M31 is well defined and exhibits a complicated structure. Inside 3 kpc the situation is complicated by non-circular motions which they interpret as being caused by gas which has been ejected from the nucleus of M31. Subtracting out these radial motions, they conclude that the nucleus is rapidly rotating, with a maximum velocity of 225 km s^{-1} at $R=400$ pc. The rotation curve falls to a deep minimum at $R=2$ kpc and then rises to 270 km s^{-1} at $R=11$ kpc, after which the rotation velocity falls off gradually. Rubin and Ford deduce a total mass for M31 out to 24 kpc, the last measured point, of $1{\cdot}85 \pm 0{\cdot}1 \times 10^{11}$ solar masses. On this basis M31 is about 20 per cent more massive than the galaxy. The rapidly rotating nucleus has a mass of $6 \pm 1 \times 10^{9}$ Suns with a mean density of 4,000 solar masses per cubic parsec inside $R=400$ pc. (This can be compared with a mean density of 0·1 solar masses per cubic parsec in the solar vicinity.)

The final implications of Rubin and Ford's work will require further theoretical study. For example, in their model the mass density falls to zero near $R=1$ kpc, which is physically unreasonable. But theirs is the most complete study yet made of the rotation of a galaxy, and it will form a solid foundation for future investigations of the dynamics of a typical spiral galaxy.

TRIBOLOGY

On the Interface

from a Correspondent

EARLIER this month, Manchester was the scene of the latest phase in industry's war with friction. With its symposium on profit from tribology, the Ministry of Technology, in association with the National Centre of Tribology (NCT), Risley, the Institution of Mechanical Engineers and the Confederation of British Industries, sought to inculcate in local industry some idea of the potential rewards from the application of tribology—the science and technology of interacting surfaces in relative motion.

On March 9 an exhibition and film were directed at senior management from more than 200 companies. Lord Delacourt-Smith (Minister of State, Ministry of Technology) recalled that in 1966 the Jost Report estimated industry's frictional losses as £500 million per year. He pointed out that this seemed an underestimate, the true figure now being nearer £1,200 million per year, of which £500 million could easily be saved by applying existing tribological expertise. In the NCT, the industrial units for tribology and the universities, Britain had this capability. Referring specifically to the NCT, he noted the pioneering work on plastic gas-bearings. These promise to be cheap, efficient, free of contamination (being greaseless) and silent.

On March 10 a technical meeting was aimed at engineers from the same companies. Dr J. F. Archard (University of Leicester) maintained that at present "the economics of tribology is more important than the science of tribology". Valuable knowledge was available, the problem was to disseminate it.

Four reasons for this under-utilization were suggested: tribology was new, it was interdisciplinary, academics were not problem-oriented, and industrialists were scared to ask too many simple questions. The obvious savings, like energy, manpower, lubricants and increases in mechanical efficiency, he said, were typically only one-eighth of the total saving tribology could provide.

The major benefits derived from consequentials such as less maintenance and longer machine life. These factors, it was claimed, sat squarely on the interface between management and technology. This interface "must not become a barricade".

Dr D. Summers-Smith (lubrication adviser, ICI Ltd) emphasized that the process industries put a high premium on reliability, since a single pump-bearing failure could shut a complete modern integrated chemical works for days and cost many thousands of pounds in lost production, whereas to replace a part could cost only shillings.

But to duplicate each component would incur a vast capital cost. Where should the line be drawn? A tribological understanding aided the choice of the cheapest bearing design commensurate with an acceptable component lifetime. In other cases, techniques like noise spectrum analysis of vibrating bearings permitted replacement weeks before failure occurred. Britain's oil industry spends several million pounds per year on research and development, maintains advanced technical services departments, and will even give companies detailed assistance with machine design.

Mr B. E. Hurley claimed (British Petroleum Ltd) many companies still adopt a costly *ad hoc* approach to lubrication problems. Dr W. H. Roberts (NCT), however, discussing case histories of problems overcome at his centre, gave some examples of huge savings achieved through the thoughtful application of tribological knowledge.

Probability, Information and Entropy

by
J. S. ROWLINSON
Department of Chemical Engineering and Chemical Technology,
Imperial College of Science and Technology,
London SW7

The claim that information theory provides a foundation for statistical thermodynamics which is independent of the use of ensembles can be sustained only if probabilities can be determined numerically without treating them as frequencies. The use of Shannon's measure of information to assign probabilities is correct only in the same conditions as justify Gibbs's use of ensembles.

If we are to perform an experiment which can have one of n different results, and the probability of result i is p_i, where

$$p_i \geq 0 \qquad \sum_{i=1}^{n} p_i = 1 \tag{1}$$

Shannon[1] showed that a unique and self-consistent measure of the ignorance of the outcome is provided by

$$H = -\sum_{i=1}^{n} p_i \ln p_i \tag{2}$$

If one result is certain, its probability is unity and ignorance is zero. Conversely, H is greatest if the p_i are all equal; $p_i = 1/n$, $H = \ln n$. Ignorance increases with the number n of possible results, that is, results for which $p > 0$. The definition of H recalls that of entropy in statistical mechanics[2], and Shannon used this name for it. The formal link between statistical mechanics and information theory was made by Jaynes[3] and has led to many useful insights. Jaynes, Tribus[4] and Katz[5] have used it as a basis for teaching thermodynamics and statistical mechanics.

The subject of this article is not the enrichment of ideas that has followed from this use of information theory, but the claim of Jaynes and Tribus that the use of Shannon's measure provides a foundation for statistical mechanics which is independent of the use of ensembles. Such a claim requires an inverse use of equation (2). We do not assume that we know p_i and calculate H, but determine the p_i by maximizing H. To examine the validity of this procedure we must ask what is meant by the symbol p_i.

Definition of Probability

Most scientists would say that the probability of an event is (or represents) the frequency with which it occurs in a given situation. If pressed further, a scientist might admit that the frequency was often taken not from an actual series of events but from an imaginary series appropriate to the model which is his idealized representation of the situation. Thus if he has a cube of sugar[4] with the faces marked, as on a die, from 1 to 6, and is asked for the probability of scoring 6 on the next throw, he will reply, 1/6. He recognizes that the cube is not strong enough for him to measure the frequency of 6 in a long series of throws, but, almost without thought, replaces the real cube by an imaginary ensemble of identical cubes each of which he supposes to be thrown once.

Such a view of probability recalls the methods used by Gibbs to establish the rules of statistical mechanics. It is rejected by Jaynes and Tribus for whom a probability is neither a frequency nor does it represent one[6]. The definition of probability is an old problem; Edwards[7] has described briefly the current spectrum of views, of which one wing is occupied by those who divorce probability from frequency, although they recognize that an observed frequency may be evidence for the value of a probability. This group can be divided into those who take an objective view (Keynes[8], Jeffreys[9]) and those who take a subjective view (Ramsey[10], Good[11], Savage[12]). The latter often assess a personal probability as the odds at which a man will bet. But because we hope that rational men will arrive at the same probability on the same evidence we need not explore this distinction here.

Probability need not have a numerical value. To take a point currently under discussion, we do not say that there is a probability of 0·7 that vapour pressure curves are non-analytic functions of temperature at critical points, although we do say that they are probably so. It would be hard to believe that we were discussing a frequency, and equally hard to attach a meaning to the number 0·7. Carnap[13] recognized a distinction between logical probability and probability as a frequency, and attempted, without real success, to find a means of assigning numbers to the former. But we must have numbers in order to use probabilities in the physical sciences. How do those who eschew the frequency definition assign them ?

The classical answer is Bernoulli's principle of insufficient reason or, to give it the name used by Keynes, the principle of indifference. In its crudest form this asserts that if there is no known reason for preferring one alternative to another, then they are equally probable. This is too sweeping, and can be used to generate inconsistencies of which Keynes and others have given numerous examples. Cox[14] has proved formally that the proposition is false. As early as 1842 Ellis (quoted on page 85, ref. 8) went to the root of the fallacy—"Mere ignorance is no ground for any inference whatever. *Ex nihilo nihil.*" Keynes reformulated the principle in a way that removes the more obvious defects, but his qualifications need not be considered here, for they do not avoid the difficulties discussed later. The modern and apparently more powerful principle of maximizing the entropy has much in common with this principle when ignorance is almost complete. For if we know only that an experiment has n possible results and maximize H subject to equation (1), then $p_i = 1/n$, as would be found from the principle of indifference.

Games of Chance

I shall now consider a problem posed by Jaynes which is relevant to statistical mechanics. A man has been playing a game of chance in which the score for each turn can be an integer from 1 to 6. He says that his average score so far is 4·5 and asks for an estimate of the probability of his scoring 1 on the next throw. Jaynes uses all the information and maximizes H subject to equation (1) and to the constraint

$$\langle i \rangle = \sum_{i=1}^{n} i\, p_i \tag{3}$$

where $n = 6$, $\langle i \rangle = 4{\cdot}5$. By using Lagrange's undetermined multipliers we find

$$p_i = z^{-1} e^{-\beta i} \qquad z = (1 - e^{-\beta n})(e^{\beta} - 1)^{-1} \tag{4}$$

$$\langle i \rangle = e^{\beta}(e^{\beta} - 1)^{-1} - n(e^{n\beta} - 1)^{-1} \tag{5}$$

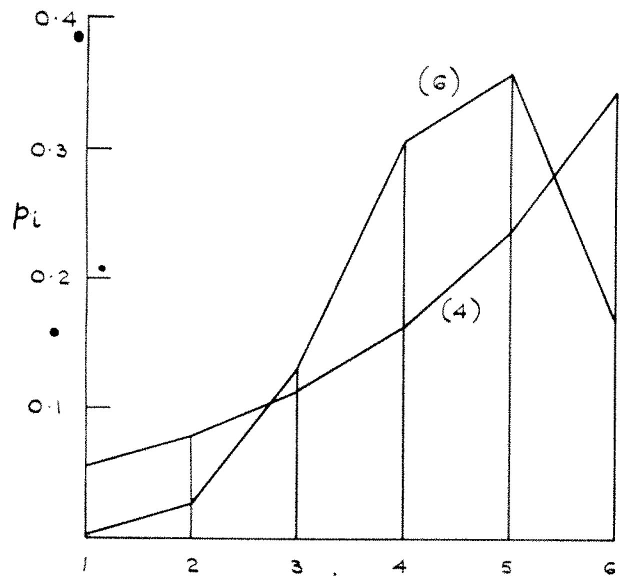


Fig. 1. Probabilities calculated from equations (4) and (6).

This distribution is shown in Fig. 1. The parameter β has the same role as reciprocal temperature $(1/kT)$ in classical statistical mechanics. At infinite temperature $(\beta = 0)$ the mean molecular energy, or score, $\langle i \rangle$, is equal to $\frac{1}{2}(n+1)$. The probability of a molecule being in level i is $1/n$. In Fig. 1, $\beta = -0{\cdot}3711$; that is, the temperature is negative because Jaynes specified a mean score which is greater than the average of the numbers 1 to 6. A physical analogue is an assembly of nuclear spins, each with six equally spaced energy levels, for which the spin–spin relaxation time is short compared with the spin-lattice time. If the mean energy per spin exceeds 3·5, then the spin temperature is negative and we have the inverted Boltzmann distribution shown in Fig. 1.

I shall consider again the game of chance. If the mean score is not known, then ignorance of the result of the next throw is ln 6 = 1·7918. When the mean score is known it follows from equation (4) that H has fallen to 1·6136, and the probability of scoring 1 is assessed at $p_1 = 0{\cdot}05435$. But what basis is there for trusting in this last number? I believe none, unless something is known of the nature of this game of chance. It might, for example, be the following.

An urn contains seven white and three black balls. It is sampled five times, and the player scores i if $(i-1)$ of the samples are white. (To sample means, here, to withdraw a ball, note its colour, replace it, and shake the urn.) This is perhaps as simple a game as could be devised which conforms with the information. A straightforward calculation of the number of ways of drawing $(i-1)$ white balls leads to the skewed-binomial distribution, also shown in Fig. 1

$$p_i = \binom{n-1}{i-1} (n-1)^{1-n} (\langle i \rangle - 1)^{i-1} (n - \langle i \rangle)^{n-i} \quad (6)$$

Thus $p_i = 0{\cdot}00243$, a result which is less than one-twentieth of that calculated from equation (4). Those who favour the automatic use of the principle of maximum entropy would observe that the entropy of equation (6), 1·4136, is smaller than that of equation (4), and so say that in proposing equation (6) as a solution "information" has been assumed for which there is no justification. This is a valid objection only if it is admitted that maximizing the entropy is a useful way of attacking the problem. I maintain, with Ellis, that on this information alone we have no means of estimating the p.

Maximum Entropy

There is a more interesting problem of which equations (4) and (6) are special solutions. There are many urns each containing many balls, black and white. A turn in the game is now played by choosing an urn at random, sampling it as before, and replacing the urn. The chance of scoring i depends on the distribution of black and white balls in the population of urns. Let there be urns with proportions of white balls of 0, $1/m$, – –, j/m, – –, 1, and let the fraction of this population that contains a proportion (j/m) be $(m+1)^{-1} f(j/m)$. Thus

$$\frac{1}{m+1} \sum_{j=0}^{m} f\left(\frac{j}{m}\right) = 1 \quad (7)$$

$$p_i = \frac{1}{m+1} \binom{n-1}{i-1} \sum_{j=0}^{m} f\left(\frac{j}{m}\right) \left(\frac{j}{m}\right)^{i-1} \left(1 - \frac{j}{m}\right)^{n-i} \quad (8)$$

$$\langle i \rangle = \sum_{i=1}^{n} i\, p_i = 1 + \frac{n-1}{m+1} \sum_{j=0}^{m} \left(\frac{j}{m}\right) f\left(\frac{j}{m}\right) \quad (9)$$

We can now take the limit as m, the number of urns, becomes infinite; when $f(y)\mathrm{d}y$ becomes the chance of choosing an urn with a proportion of white balls between y and $y + \mathrm{d}y$, and equations (7) and (9) become

$$\int_0^1 f(y)\mathrm{d}y = 1 \quad \langle i \rangle = 1 + (n-1) \int_0^1 y f(y)\mathrm{d}y \quad (9a)$$

We cannot calculate p_i until we have chosen the prior probability distribution function $f(y)$. One choice is a delta-function at $y = 0{\cdot}7$, the value that satisfies (9a). All urns then have the same proportion of white balls and p_i are given by equation (6). We can, however, spread $f(y)$ as widely as possible between 0 and 1, consistent with equation (9a). To do this we maximize the entropy of the discrete distribution, subject to (7) and (9), and then proceed to the limit of infinite m. The result is

$$f(y) = \beta e^{-\beta y} (1 - e^{-\beta})^{-1} \quad (10)$$

$$\langle i \rangle = 1 + (n-1)[\beta^{-1} - (e^{\beta} - 1)^{-1}] \quad (11)$$

$$p_i = \binom{n-1}{i-1} \int_0^1 f(y)\, y^{i-1} (1-y)^{n-i}\, \mathrm{d}y \quad (12)$$

These equations require $\beta = -2{\cdot}6721$ and give p_i close to those of equation (4). We find $p_i = 0{\cdot}05179$ and $H = 1{\cdot}6134$, a difference of entropy of 0·0002. Equations (4) and (12) become identical if $(n-1)$, the number of times an urn is sampled, becomes infinite. Spreading the prior probabilities according to equation (10) may seem to be less arbitrary than choosing a delta-function, but there are no grounds for thinking it to be more correct if nothing is known of the principle on which the urns were filled.

In this example, maximizing the entropy has the same result as following a postulate of Bayes and Laplace[11] (not Bayes's theorem), namely, that if the prior probabilities are not known they should be distributed uniformly. If, as in this case, the information that $\langle i \rangle \neq \frac{1}{2}(n+1)$ rules out a strictly uniform distribution, $f(y) = 1$, then maximizing H gives a rule for obtaining as wide a distribution as possible. The rule is therefore an adaptation of two old principles—that of indifference and that of Bayes and Laplace—to situations where there is not total ignorance of the distribution of probabilities.

It must now be admitted that the first problem is not exactly as stated by Jaynes[15], who said that the "game of

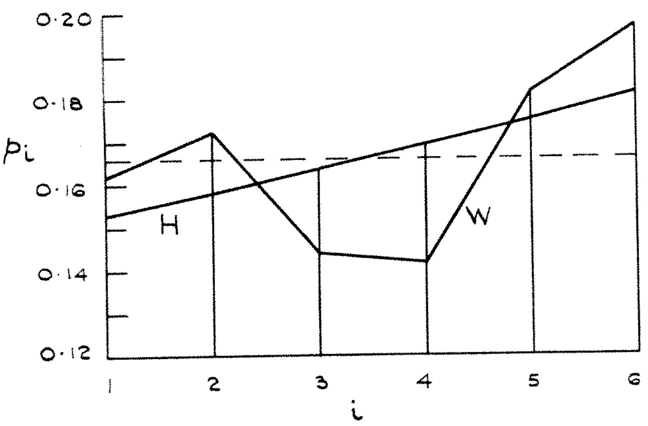

Fig. 2. The frequencies observed by Wolf (W) for a die for which $\langle i\rangle = 3{\cdot}5983$; the probabilities ($H$) calculated by maximizing the entropy for the same value of $\langle i\rangle$. The dashed line is the random result $p_i = 1/6$.

chance" was the throwing of a loaded die. How does this restriction affect the argument ? Clearly we shall now be less likely to entertain the binomial distribution (6), but is there anything in the mechanics of throwing dice which suggests that if a die is not true the probabilities of scores of 1, 2, – – 6, should form the geometrical progression (4) ? I think not. In 1883 Wolf[18] made 20,000 throws of a pair of dice; one of them, the white die, was untrue and gave $\langle i\rangle = 3{\cdot}5983$. The frequencies of the six scores are shown in Fig. 2, which shows that their departures from the random value of 1/6 bear no resemblance to those calculated from the rule of maximum entropy.

What is clearly wrong with the indiscriminate use of this rule, and of the older rules from which it stems, is that they ignore the physics of the problems. Until we know something of the mechanics of dice, or of how the balls got into the urns, we can say almost nothing about p_i. In statistical mechanics we understand sufficient of the physics; in particular we know that if we could follow the evolution of a system for a short time we should find that the final microstate was extremely sensitive to changes in the specification of the initial state. It is such knowledge, not ignorance, which justifies us in supposing that a Gibbs ensemble might be an appropriate model from which to calculate p_i. (Because the rules of statistical mechanics cannot be deduced from those of mechanics, the final justification of this supposition is, as always, the agreement of its consequences with experiment.)

Similarly, if we estimate $p_i = 1/6$ for an untested but apparently quite normal die, then we do so because we know that the result of throwing a die is also extremely sensitive to the initial state, that is, to its momenta and orientation as it hits the table. Thus, we calculate p_i by an analysis similar to that which is used to calculate the probability that a nuclear spin is in level i in a system at infinite temperature, $\beta = 0$. If we have less confidence in predicting the result of throwing a loaded die by the analysis we use for a spin system at $\beta \neq 0$, then Wolf's results show that our lack of confidence is justified. If we assert that a man who lays his bets according to the principle of maximum entropy will, in the long run, beat a man who does not, then we are expressing an opinion on the physics of the situation on which they are betting. If we specify p_i by a precise number we are stating a frequency in an ensemble of our choosing. The principle of maximum entropy is a useful rule, but its validity is no wider than can be justified by the interpretation of probability as a frequency in a Gibbs ensemble, or in any analogous ensemble if the problem is not one of physics.

Failure to make a satisfactory division between those parts of a problem that are physical and those that are mathematical, that is, between the synthetic and the analytic, may well be at the root of other difficulties in the theory of probability. If probability is defined as a frequency in an ensemble[17-19], then the analysis is straightforward in principle, even if difficult in practice. The ability of the ensemble to represent the problem is a matter of physics, not of logic, and insuperable difficulties arise if we try to bring the justification of the ensemble into the analysis of probabilities.

The paradox of the relevance of evidence discussed, in different forms, by Ayer[20], Bartlett[21] and Popper[19] may serve as a final illustration. We have an untested but apparently normal die; we maximize H and obtain $p_i = 1/6$, $H = \ln 6$. We throw the die 999 times and find that all p_i are close to 1/6; it is shown to be a true die. We are now asked to estimate p_i for the thousandth throw, and to recalculate H. We obtain the same answers, and have therefore apparently learnt nothing from our experiment. Lewis[22] admits this, and says we have gained no information from the 999 throws. He is correct if the word information is being used in the technical sense of equation (2). The experiment has, however, confirmed the initial hypothesis about the physics of the problem, namely, that in calculating p_i for a throw of this die it was appropriate to use an idealized ensemble of true dice. There are several schemes for attaching a number to this degree of confirmation[19], or support[23] or increase in likelihood[7] of the initial hypothesis, but such numbers are not probabilities (that is, they do not conform to the usual rules of the calculus of probabilities), and they play little or no part in the physical sciences.

I thank Dr K. G. Denbigh for helpful comments.

^{14}C Amino Acids from Schwarz/Mann

DIVISION OF BECTON, DICKINSON AND COMPANY BD

Examples of the unusually high specific activities available from Schwarz/Mann:

L-[^{14}C] Alanine	159mc/mM	L-[^{14}C] Lysine	320mc/mM
L-[^{14}C] Arginine	320mc/mM	L-[^{14}C] Methionine	255mc/mM
L-[^{14}C] Aspartic Acid	212mc/mM	L-[^{14}C] Phenylalanine	455mc/mM
[^{14}C] Glycine	106mc/mM	L-[^{14}C] Threonine	212mc/mM
L-[^{14}C] Leucine	320mc/mM	L-[^{14}C] Tyrosine	455mc/mM

Further re our high specific activities: ALL of our ^{14}C amino acids are higher than 50mc/mA. About purity. Every lot of phenylalanine and tyrosine is repurified every month. Every lot of everything else: reassayed every ten weeks and repurified if necessary. And *all* assay and reassay data goes onto the Product Analysis Report that you receive. About availability: these compounds are available *from stock*. For the complete story on our complete labeled amino acid line call (914) 359-2700 or write: Schwarz/Mann, Orangeburg, New York 10962. Division of Becton, Dickinson and Company.

^{3}H AMINO ACIDS FROM SCHWARZ/MANN

Examples of the unusually high specific activities available from Schwarz/Mann:

Catalytic

L-[^{3}H] Alanine	6c/mM
L-[^{3}H] Arginine	10c/mM
L-[^{3}H] Histidine	8c/mM
L-[^{3}H] Lysine	6c/mM
L-[^{3}H] Phenylalanine	7c/mM
L-[^{3}H] Valine	8c/mM

Specifically Labeled

L-[4^{3}H] Arginine	20c/mM
L-[2,3^{3}H] Aspartic Acid	15c/mM
L-[3,4^{3}H] Glutamic Acid	15c/mM
L-[4,5^{3}H] Leucine	50c/mM
L-[4,5^{3}H] Lysine	20c/mM
L-[5^{3}H] Proline	15c/mM
L-[2,3^{3}H] Valine	15c/mM

These high specific activity ^{3}H-labeled amino acids are reassayed every ten weeks—as is *every* radiochemical we make—and repurified when necessary. All relevant analytical data gets forwarded to you. For detailed information call (914) 359-2700 or write: Schwarz/Mann, Orangeburg, New York 10962. Division of Becton, Dickinson and Company.

American Museum of Natural History at 100

by

JAMES A. OLIVER

American Museum of Natural History,
New York 10024

The centenary of New York's Museum of Natural History, which continues until May this year, has been marked by the beginning of some important new programmes, particularly concerned with the environment. In this article, the former director, now coordinator of the museum's scientific and environmental programme, traces its history and describes some new departures for the next hundred years.

THE American Museum of Natural History was conceived and founded when the intellectual community was experiencing either exhilaration or mental indigestion depending on the individual's viewpoint. The cause of these disparate sensations was Charles Darwin's *The Origin of Species*. In addition to producing a widespread philosophical debate, both in and out of scientific circles, the book resulted in a great increase of interest and curiosity about the natural sciences. Thus in the 1860s the climate was favourable for Albert S. Bickmore, a young student of the renowned Swiss naturalist, Louis Agassiz, to enlist the sponsorship and financial support of a group of New York City's socially prominent men for the founding of a new museum of natural science. The American Museum of Natural History was officially chartered on April 9, 1869, when the Governor of the State of New York signed the enabling legislation for "the purpose of establishing and maintaining . . . a Museum and Library of Natural Science; of advancing the general knowledge of kindred subjects, and to that end of furnishing popular instruction".

When the first small exhibition of mammals, birds, and reptiles opened in temporary quarters in the spring of 1871, visitors were largely the élite of New York's adult society coming to view the curios of nature. Today, the museum occupies its own home in nineteen connected buildings covering twenty-three acres of floor space, and its nearly four million annual visitors come from all walks of life and nearly all parts of the world. Approximately 60 per cent of them are below college age. They come to the museum for a wide variety of reasons—with interests that usually go far beyond curiosity about the strange or the odd, the dwarf or the mammoth (although some 40,000 visitors arrived in four hours recently to view a moon rock). Today most visitors are seeking answers to urgent questions that bear on the survival of man and of the hundreds of thousands of species of animal and plant life with which he shares his planet; questions about the other planets in the solar system; questions about the characteristics of the men and women of other cultures and other societies. They view the museum as a place to find new insights into the meaning of their lives and new understanding of themselves and their fellow men.

When the first permanent building of the museum was opened by the President of the United States, Rutherford B. Hayes, on December 22, 1877, Professor Othniel C. Marsh, director of Yale University's Peabody Museum of Natural History, remarked: "These vast collections will spread the elements of Natural Science among the people of New York and the surrounding region, but the quiet workers in the attic who pursue Science for its own sake, will bring the Museum renown throughout the world". Few will debate those prophetic words. In spite of the museum's many other claims to international recognition, it has been scientific research that has established the world-wide reputation of the institution.

Growth of the Collections

At first the activities of the small scientific staff were simply to collect, classify, catalogue, and sometimes exhibit the forms that occurred in remote areas. The first official expedition was launched in 1887 when Joel A. Allen set out to collect mammals in the western United States in the area later designated as the state of Montana. The 1890s saw a series of expeditions by the Department of Vertebrate Paleontology to western North America for Mesozoic and Tertiary vertebrates, and the Jesup North Pacific expeditions of the Department of Anthropology, conducted from 1897 to 1903. The first thirty years of the twentieth century were the "golden age of exploration" and many large scale, long term and highly successful expeditions were sent to various parts of the world resulting in rich collections of scientific specimens and priceless exhibition material: the Lang–Chapin expedition to the Congo for reptiles, birds, and mammals; the 1921–30 Central Asiatic expeditions led by Roy Chapman Andrews, and in 1920–29 the Whitney South Sea expeditions primarily for birds but including other recent groups.

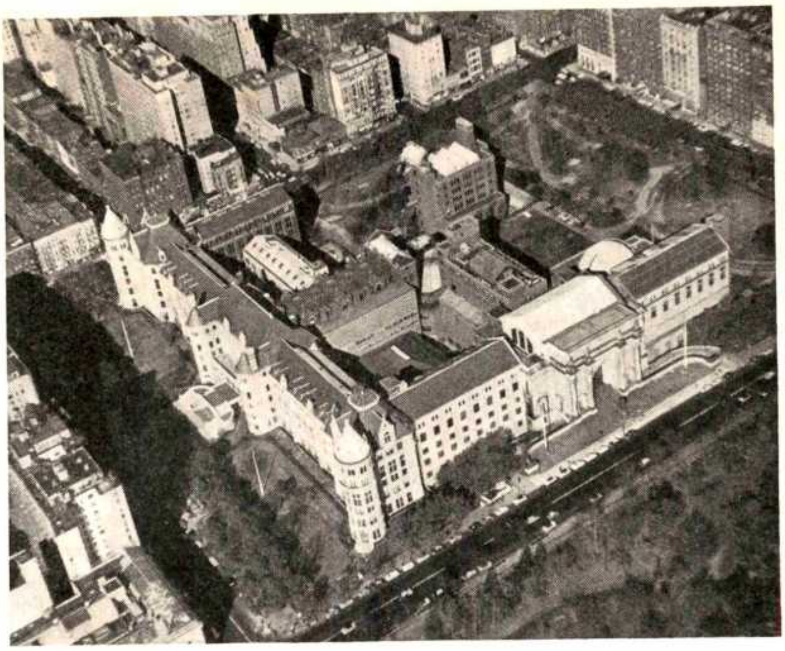
The Second World War cut down expeditions and later, when air travel became more common, the purposes and nature of expeditions, their size and span, changed. Today, two or three individuals may go for short periods of time to gather or verify observational or experimental data or to gather new information and record it on electric and electronic equipment that greatly facilitates the collection and verification of new data.

Changing Research Trends

The research activities of the scientists at the museum evolved from classical, descriptive, taxonomic and morphological studies of the collections into broader, more analytical, and more inclusive investigations. As the theories of Darwin became more widely accepted, and were verified and modified, biology turned to inquiries into the mechanisms by which evolution works, the relationships of the known forms of life, the causes of extinction, the modes of adaptation and the behaviour of organisms.

Much of the scientific information that increased knowledge of the workings and results of evolution came from vertebrate palaeontology and systematic biology. The American Museum of Natural History was fortunate in attracting a brilliant palaeontologist, Henry Fairfield Osborn, who served its cause vigorously, imaginatively, and productively as scientist, trustee, and president. Osborn was one of the most effective individuals to have been associated with the museum in its first hundred years. The programme in vertebrate palaeontology that he established in 1891 has grown into the largest centre for this kind of research in the world, and science and the museum continue to benefit directly and indirectly from his influence.

The scientists, field collectors, preparators and students attracted by Osborn established a long and flourishing



Aerial view of the New York Museum of Natural History.

line of prominent vertebrate palaeontologists. Beginning with William Diller Matthew and William King Gregory, the group also includes Walter Granger, Barnum Brown, and Roy Chapman Andrews, and George Gaylord Simpson, Edwin H. Colbert and Bobb Schaeffer. Only recently, the museum received a substantial bequest that represents yet a further indirect blessing from Henry Fairfield Osborn. In 1967 the heirs of the late Childs Frick donated to the museum Frick's incomparable collection of fossil vertebrates, including the largest and most extensive series of North American Tertiary mammals in any collection, and provided an endowment of more than $7·5 million for construction of a new building to house the collections and to provide funds for continuing studies on these fossils. The acquisition of this collection—approximately equal in bulk to the entire fossil vertebrate collections of the museum—and the personnel to look after and study it gives the museum an unrivalled position as the leading centre for the study of vertebrate palaeontology. Frick was a close personal friend and protégé of Osborn. The new building now under construction will be known as the Childs Frick Wing of Vertebrate Paleontology.

Anthropology has also been emphasized from the early days of the museum. Starting about the same time as the programme in vertebrate palaeontology, the activities that centred around the study of man first concentrated on North American archaeology and ethnology. The pioneering studies of Franz Boas, Clark Wissler and Nels Nelson contributed greatly to knowledge of pre-European and native peoples of North America. The tradition of excellent archaeological work has continued to the present, and has been complemented by notable contributions in physical anthropology, ethnology, and social anthropology through the studies of such staff members as Harry Shapiro, Junius Bird, Gordon Ekholm and Margaret Mead.

At first taxonomic studies on recent forms of animal life were mostly confined to mammals and birds, with Joel A. Allen and Frank M. Chapman in charge of the respective groups. New programmes and departments were developed to cover each class of vertebrates, insects, spiders, crustaceans, molluscs, parasitic and marine worms, and foraminifera. During its history the museum has experimented with different administrative alignments of its departments and with various specialty departments. Today, there are twelve scientific departments with a hundred active scientists conducting 300 research projects. All but two of the departments, astronomy and mineralogy, are concerned with some form of animal life.

Taxonomic studies evolved into the broader fields of systematic and evolutionary biology as knowledge accumulated. In fact, many museum staff members have made substantial contributions to the development of the "new systematics". Especially notable is the work of Ernst Mayr and George Gaylord Simpson, both of whom produced numerous major publications while they were on the staff of the museum. The emphasis on systematic and evolutionary biology has expanded the interests of the staff, enlarged the value of the collections and increased the demands for new equipment and new techniques. Studies of live animals often augment and complement investigations on the preserved collections.

Animal Behaviour

The study of animal behaviour has been described as one of the oldest preoccupations of man but one of the youngest sciences. Although many other departments study some aspects of animal behaviour in the process of their systematic research, this department is concerned solely with behavioural investigations. In 1928 Dr G. Kingsley Noble established a division of experimental biology. It became a full department in 1933 and in 1942 was renamed the Department of Animal Behavior. The staff of this department, who study both invertebrates and vertebrates including man, have been pioneers in this complex and difficult field. Much of the work in the department has been organized toward comparative studies on animals of various phylogenetic levels and is aimed at gaining an understanding of how the combined forces of external and internal stimuli interrelate to

The façade of the Theodore Roosevelt Memorial Building of the New York Museum of Natural History.

determine the behaviour of the animal. Work in progress includes studies of the different bases for and forces involved in socialization in insects, fish and mammals; the psychobiological development of emotional reactions and sexual behaviour in mammals; the role of sound production, underwater hearing and communication in fishes.

The effectiveness of researches such as those being carried out by the staff of the museum is related to the supportive facilities for research. The library of approximately a quarter of a million volumes of natural history references is one of the best in the world. Because of the excellence of the library the National Science Foundation is supporting pilot projects in bibliographic processing techniques in ichthyology and herpetology.

The museum operates five field research stations primarily for the use of its own staff, but also open to other qualified scientists. These are the Archbold Biological Station in south-central Florida; the Lerner Marine Laboratory on the island of Bimini, Bahamas; the South Western Research Station in Arizona; the Kalbfleisch Field Research Station on Long Island, New York; and Great Gull Island off the north-east coast of Long Island, New York. All but the last named have resident staffs and permanent laboratory and living facilities.

Programmes of Education and Exhibition

Albert S. Bickmore was an enthusiastic educator, and it was not surprising that he soon augmented his exhibition of real objects with lectures. His first programmes were for teachers, but he went on to include "artisans, mechanics and other citizens". Demonstrations for school children followed, attendance increased, and the success of the programme led to the establishment, in 1884, of the Department of Public Instruction. The name of the department has been changed several times in the eighty-five years of its existence, but the continuity of its function has been unbroken. Known today as the Department of Education, it has the largest teaching staff of any museum. Its activities for young people range from formal programmes for the school children of New York, which are correlated with the school syllabuses in science and social studies, to classes for both the mentally retarded and the intellectually gifted, and include visits to children confined in hospitals.

Programmes for adults range from the highly popular bird walks and field trips for laymen, conducted in the parks and sanctuaries of the metropolitan New York area, to specialized, intensive courses for biology teachers. Bickmore's early tradition of innovation and pioneering has been continued, and programmes such as a course for nurses in the anthropological and natural sciences, initiated in 1931, provide an understanding of ethnic and cultural differences. Graduate training programmes are conducted by members of the scientific staff in cooperation with universities in the New York area. Candidates for higher degrees receive both formal instruction and project guidance in this programme, which was initiated more than eighty years ago.

An important arm of the museum's education programme is the American Museum–Hayden Planetarium, directed by the Department of Astronomy. A relatively new addition to the museum complex, this has become a vigorous element in the teaching of astronomy and related Earth and space sciences. Youngsters may begin their education in these fields at the age of eight, and continue throughout their adult lives, if their interests and capabilities orient them to subjects such as celestial navigation and astronomy for engineers.

The museum has long had an active publication programme in both scientific and popular work. The *Bulletin*, the *Anthropological Papers*, and the *American Museum Novitates* are the primary scientific journals, and from time to time large monographs and miscellaneous papers are also published. For more than a quarter of a century the comprehensive *Catalogue of Foraminifera*, now in its seventieth volume, has been published at the museum. Publication of the twenty-nine volumes of the *Catalogue of Ostracoda* was undertaken in 1952 and the quarterly journal *Micropaleontology* was initiated in 1954.

Besides the scientific publications the museum has for the past thirteen years published a quarterly magazine for the profession entitled *Curator*, which covers such

Alaskan moose in the hall of North American mammals.

varied aspects of museum studies as a description of the preparation of archaeological objects for display, and the use of data storage and retrieval systems to enhance the usefulness of museum collections. Many popular books and three popular magazines have also been part of the publications programme. The first children's magazine, *Junior Natural History*, was superseded in 1963 by *Nature and Science*. *Natural History*, now in its 70th year of continuous publication, is directed toward the informed lay public. Its editorial scope and content have been broadened as the museum has expanded its fields of study and interest.

But the most potent educational force of the museum is its exhibition programme. From 1871, the date of its first public exhibit, the museum has always attempted to innovate and to set new standards of excellence in its displays. Its first modest effort at the habitat style of presentation, in 1886, was a pair of robins shown with their nest on the bough of an apple tree, and for many years the major effort was directed toward the creation of large and small, but always true to life, habitat exhibits, always constructed on the firm foundation of competent scientific authority. As knowledge has increased, the museum has endeavoured to keep pace with current scientific information, but occasionally the high cost of creating these exhibits resulted in a rather prolonged span between the desire for change and the time of the actual change. One "temporary exhibit" lasted forty years.

Habitat groups, many built under the creative and artistic direction of Carl Akeley and later James L. Clark, were the most spectacular types of exhibits shown by natural history museums for many years, and some of the largest and most ambitious of those halls were built at a cost of more than a half million dollars each. Today, although the great habitat halls still attract vast throngs of visitors, the museum is using many other methods of display to increase the educational impact of its fifty-eight exhibition halls. Exhibit labels are augmented or replaced by audio messages. Animated exhibits, films, slide displays, graphics, recorded sounds and music all complement the real, three-dimensional object or model. Many of the new techniques are seen in the halls developed in the last ten years.

Centenary Activities

In 1959 the Board of Trustees and the City of New York jointly adopted a major expansion of the exhibition programme in preparation for the centenary year. As a result, fifteen permanent exhibition halls have been completed and twenty special or temporary exhibits were opened including the halls of Indians of the eastern woodlands and plains, biology of the invertebrates, the John Lindsley hall of earth history (which has one of the few working seismic recorders on public display), ocean life and biology of fishes, man in Africa, and the hall of Mexico and Central America, which is scheduled to open in the spring of this year.

The exhibition of ocean life and biology of fishes fills the largest hall in the museum, a duplex area 80 feet wide by 135 feet long by 50 feet high. On the balcony are fifteen dioramas of life in and adjacent to the seas, and an exhibit of the phylogeny of fishes in which some 400 models are displayed. Suspended from the ceiling is a life-size model of a breeching blue whale, 94 feet long, which has rapidly become one of the most popular attractions in the museum and in the City of New York.

Another of the highly effective centennial exhibitions is the hall of man in Africa which draws many visitors from the black community. This hall, by telling the story of man in his varying African environments and showing the richness of his cultural heritage, corrects misunderstandings about the nature of traditional life in Africa.

John Canaday, art critic of *The New York Times*, described the hall as "a fine demonstration of museum craftsmanship using a superb collection of African art as its major source of raw material. . . . It illustrates the dignity and richness of African tribal life and culture before their corruption by European influences, and does so without sentimentalizing or propagandizing. . . . It is the breadth of this perspective that makes this view of man and Africa so revealing and so enlarges our perception of his art as an integral force in his life".

The most recent and striking departure from the characteristic three-dimensional museum display is the special centennial exhibit, "Can Man Survive ?". This exhibit, using very little three-dimensional material, is designed to provide an environment isolated from the rest of the museum, in which the visitor is exposed to various media, from electronic music and flashing neon lights to psychedelic murals. The effect, generally very successful, is to produce in the visitor an awareness of what man has done, and is doing, to the environment. As the visitor walks through the truss in which the

Savannah culture, religion and economy in the peoples of Africa hall.

exhibit is suspended, the noise level rises higher and higher, the passageway narrows, the lights flash with increasing intensity. All around him are examples of man's insults to the environment and the message is brought home: "It's up to you !" Man can survive only if he cares about the quality of life, protects the resources of our planet, and acts wisely—now.

Environmental Studies

The centennial exhibit is a striking re-emphasis in a century of concern by the museum about the biophysical environment and the wise use of the Earth's resources. Dr Frank M. Chapman, the first curator of birds and chairman of that department, was a leader in conservation programmes in the United States and in Latin America, and the staff of the Department of Ornithology who followed him have all been active in wildlife protection. This concern has been shared by many other staff members through the years, and the museum has at various times held formal programmes in conservation and the study of ecology.

As the museum enters its second century, it has declared its commitment to define and help solve the urgent problems of the environment. Museum scientists, who have studied the ample records of fossil life, know the tenuous nature of the existence of a species. They are aware that man, the often brilliant innovator and technologist, is primarily a biological being—dependent on requirements similar to those of other living organisms. Thus the museum has established a museum-wide, interdisciplinary programme of environmental studies to assist in mustering its scientific and educational resources to this cause. The American Museum of Natural History feels that it can help lead the way to a better understanding among men through studies of human behaviour and of individual and group differences and through explorations of the causes of aggression and conflict. It can contribute to the solution of urban problems through multidisciplinary studies by anthropologists, ecologists and behaviourists; it can help bring about awareness of the price of biological mismanagement and the dangers of overpopulation, famine and pollution that confront us, and, finally, it can help in the development of wise public policies based on public understanding of science and the natural world.

Much of the knowledge needed to achieve these goals is still to be gathered, but a great deal of the information that can illuminate these environmental problems is to be found within the collections, and in the reference materials of the scientific departments, as well as in the minds of the scientists. These resources must be mobilized and directed toward the solutions of these critical problems. Research programmes now under way can be expanded and new projects initiated, both by the scientific departments and in cooperation with other agencies, to include necessary investigations into wise methods of protecting threatened ecosystems, of increasing or expanding sources of protein foods, and of better understanding the stresses of urban life. New educational programmes and exhibits will be developed to assist in providing a wider public understanding of the urgency and scope of the problems, as well as to further the development of wise solutions to the ecological problems.

Centennial Capital Campaign

On January 9, 1970, the museum announced the inauguration of a drive to raise $25,000,000 in capital funds, in order to enhance and enlarge its facilities as it moves into its second century. It is the first such campaign in the history of the institution and the first broad public appeal the museum has made for funds.

The money will be used for the perpetuation of science teaching programmes, the conduct of scientific research, the development of new exhibition halls, and the modernization of the old, and in places creaking, physical plant. Additional funds, in the range of $35,000,000, will be sought from governmental sources for a construction programme to bring a new building for the library, a new research laboratory building, a new education building and air conditioning.

Mr Gardner D. Stout, president of the museum, announcing the drive for funds, said: "The economies of the past were necessary, and forced the deferral of needed and vital improvements. We can no longer defer these needs, and in my presidency we shall see that they are carried out." He pointed out that the museum's responsibilities were increasing at an explosive rate as scientific and environmental problems engulf the world. Dr Thomas D. Nicholson, director of the museum, said: "The museum is respected and recognized as a great teacher of science, because it has been in the forefront of the acquisition of knowledge. We teach from the authority of sound research." He added that the museum would build large exhibits in the style of the world's fairs and extend its use of multi-media presentations. Support for the interrelated science and education programmes will account for a major portion of the funds to be raised. Thus the programmes begun in the museum's first century will be developed and expanded in the challenging years ahead.

Thermodynamics makes Progress

by
P. T. LANDSBERG
Department of Applied Mathematics
and Mathematical Physics,
University College, Cardiff

On April 1–4 the Institute of Physics and the Physical Society is to hold an international conference on thermodynamics at Cardiff. This article, by one of the organizers, highlights some of the topics which are likely to provide particular interest for the participants.

WHILE it is natural to ask "What is new in pulsars ?" or "What is new in solid state devices ?", few people would ask "What is new in thermodynamics ?". Yet at the boundaries of thermodynamics, as well as at the foundations, there is considerable scientific activity. Indeed, the intrinsic interest of the subject becomes more manifest when we ask: how is it that thermodynamics, with an ever increasing entropy, permits an apparently unstructured fireball (which was the original state in a big bang cosmology) to give rise to the highly structured (low entropy ?) universe which we see around us ? This is not an easy question even for a thermodynamicist, and it illustrates well the universality as well as the difficulty of the subject.

There are, however, several more standard centres of scientific activity. In the first place, of course, the formalism of the subject expands with each really original application. There are, for example, the generalizations required to discuss the properties of ensembles which contain a small number (N) of "pieces" or systems. For an ensemble open to c chemical components[1]

$$E = TS - pV + \sum_{i=1}^{c} \mu_i N_i + \xi N$$

where E, S, V and the N_i refer to the total ensemble. The new variable

$$\xi \equiv (\partial E/\partial N)_{S,V,N_1,\ldots N_c}$$

is a kind of positive or negative "subdivision energy". It is determined by adding systems to the ensemble and evaluating the change in energy at constant entropy, volume and particle numbers N_i for each of the components i. The average small system variables such as energy, entropy, volume, particle number for component i are

$$\bar{E} = E/N, \bar{S} = S/N, \bar{V} = V/N, \bar{N}_i = N_i/N$$

It follows that the average small system energy E is not a linear homogeneous function of the small system variables, $\bar{S}$, $\bar{V}$, $\bar{N}_i$, owing to the existence of the energy ξ. This tends to zero as all $N_i \rightarrow \infty$. The terms in ξ are in the nature of correction terms which are important, for example, in colloidal systems.

Physically related, but mathematically distinct, problems arise if a system has a large surface area so that the terms arising from the nature of the surface make a notable contribution to the density-of-states function. For an ideal gas of particles of mass m in a box of surface area A and volume V, for example,

$$N(E) = a_3 \, l^3 \, V + a_2 \, l^2 A + a_1 \, l \, L + R(E)$$

Here L is a mean total curvature, $R(E)$ is a residual term, $l \equiv (2mE/\hbar^2)^{1/2}$, and the as are numerical factors of order 1/40. These correction terms lead to a purely quantum mechanical effect which requires surface and curvature tensions to be introduced into the thermodynamic quantities even of the ideal gas[2].

Rapid progress is being made at present in several closely related topics which are intermediate between thermodynamics and statistical mechanics. First, there is the behaviour of thermodynamic functions near a critical point. What happens to these functions ? Are they analytic in their arguments ? These questions are usually approached by representing a quantity which diverges at the critical point by a power of T–T_c where T_c is the transition temperature. Thus an exponent is associated with this quantity. The next question is how these exponents are related (this may be called exponentology). For example, for a van der Waals gas

$$p = AT\,(v - b)^{-1} - a\,v^{-2}$$

so that the isothermal compressibility is

$$K_T \equiv -\frac{1}{v}\left(\frac{\partial v}{\partial p}\right)_T = \left[\frac{AvT}{(v-b)^2} - \frac{2a}{v^2}\right]^{-1}$$

At the critical point $v = v_c = 3b$ and $T = T_c = 8a/27bA$, so that for $v = v_c$ indeed

$$K_T = A\,(T - T_c)^{\gamma}\ (A = 4b/3A, \gamma = -1)$$

The coefficient of volume expansion has the same form with

$$A = 2/3 \text{ and } \gamma = -1$$

Careful recent studies on argon and other fluids furnish the experimental data for this work. In ferromagnets, when the critical point is replaced by the Curie point, and in binary mixtures, similar critical phenomena occur. The values of the exponents are being estimated. Symmetry and other requirements yield relations between the exponents, and the resulting laws are called scaling laws[3]. The divergence troubles at the critical point are, roughly speaking, due to the possibility of large fluctuations in macroscopic variables and their long lifetimes.

Divergences in transport coefficients are also being studied and the laws here are sometimes called "dynamic" scaling laws[4]. There is a great deal of experimental and theoretical work to be done on this topic, and even the "static" scaling laws and the associated numerical values must be established with greater accuracy.

Limiting Behaviour

Also between statistical mechanics and thermodynamics is the question of the limiting behaviour of statistical mechanical systems when the number of particles N and the volume V both tend to infinity, subject to N/V remaining at some fixed value. This limit was investigated before the Second World War in the case of simple systems[5], and a systematic treatment is possible for all ideal gases (ref. 6, page 427). In the 1950s the limit was called "the limit L"[7]. Considerably more work has been done and the name "thermodynamic limit" has established itself, although not everyone thinks this name is a happy choice[8]. In the case of interacting particles the existence in the limit of a free energy per particle was first discussed in 1949 by van Hove for classical systems. In 1962 the results were extended by Ruelle to a more general class of systems. Existence theorems have, of course, a rather abstract flavour[9]; nonetheless, it is important that these functions are available in the limit, for this limiting procedure can be used to simplify discussions of phase transitions and theories of interacting systems in statistical mechanics.

There is a related topic intermediate between thermodynamics and statistical mechanics. When energy, volume and the number of particles are fixed for a system, one type of ensemble is needed (the microcanonical one) to describe the system in statistical mechanics. When the energy is replaced by the temperature in this specification, the so-called canonical ensemble is needed, and when, in addition, the number of particles is replaced by the chemical potential in the above specification, a grand canonical ensemble is needed. It is important to know whether these various ensembles yield similar thermodynamic functions if one and the same system is treated theoretically by any of them. This is in general not so, however, except in the thermodynamic limit. This leads to another problem which is under discussion at present, namely the asymptotic equivalence[10] of the various statistical mechanical formalisms. Except in certain special cases of phase transitions and fluctuations, these formalisms are subject to a kind of boundary condition: given a system which is described by various ensembles, its thermodynamic properties must nevertheless be ensemble-independent. The establishment of such arguments and their perfection has made considerable progress recently.

Irreversibility

The concept of irreversibility in thermodynamics and statistical mechanics has exercised scientists since Boltzmann and the Ehrenfests struggled with it. One problem is to understand thermodynamic irreversibility for a closed system in terms of mechanics and its reversible equations of motion. Where do we look for the origin of this irreversibility ? Is it in the nature of the Hamiltonian and the interaction terms which occur in it[11] ? Is it in the coarse graining of phase space, which is required to take account of the fact that all measurements are macroscopic ? (Here it is necessary to note that the fine grained entropy of a closed system remains constant in time[12].) Is it due to the impossibility of completely isolating a system from the rest of the universe[13] ? Or is the essential step the passage to the limit of an infinite number of degrees of freedom[14] ? Although a great deal of work has been done, there is still no agreement on these matters[15]. Information theory can be used[16] to elucidate some of these questions and this theory has been fully used in some books on statistical mechanics[6]. The explanation of its use in this context is being further refined[17]. At the same time the exact formal solutions of the reversible equations of mechanics have been made a starting point for the discussion of irreversibility. An important part has been played by the Liouville equation and its mathematical discussion is leading to new mathematical approaches developed particularly by Zwanzig[18] and the Brussels school[19].

Returning to purely macroscopic theories, there are noteworthy developments in formulating a broadly based theory of real solids which display thermomechanical and thermoelastic effects, and of real fluids which display viscosity and heat conduction. These theories can perhaps be called the thermodynamics of "real" materials. They operate with momentum and energy balance, with balance of moment of momentum, with the second law (also called the Gibbs–Duhem inequality by these authors[20]), and with new assumptions not present in classical thermodynamics[20]. Among these principles is that of material frame indifference, also called the principle of material objectivity. This has a long history and states that constitutive equations must be form-invariant with respect to rigid motions of the spatial frame of reference. There is also the principle of equipresence which states that a quantity which is present as an independent variable in one constituent equation must be assumed to be present in all such equations for a material (unless the contrary can be established). These theories are at present formulated in an abstract manner. While it is not clear to what extent they will yield new understanding of experimental findings, it is highly desirable that their power of synthesis be more widely understood.

One of the more obscure problems in thermodynamics proper is the discussion of self-gravitating systems[21]. In this case long range correlations cause difficulties. Relatively little is known about this topic so far. Is it possible to have a proper thermodynamics which takes account of gravitating bodies ? Or does the absence of equilibrium prevent one from establishing any form of thermodynamics for gravitating systems ?

Astrophysics and Thermodynamics

Astrophysics offers thermodynamic problems in extreme conditions of pressure and temperature. These include the possibility of surprising hypothetical systems of superdense matter in which the velocity of sound (propagated by "particles" of zero rest mass) exceeds the velocity of light in vacuum[22]. Several theoretical schemes which lead to this result have been studied. In this area lies also the question of whether cosmology can illuminate the irreversibility observed locally. Some very interesting, if speculative, discussions on this subject have recently taken place on this topic among some leading scientists. They have been edited by Gold (*The Nature of Time*, Cornell, 1967) and contain, among other things, discussions of the view that the irreversible character of physical processes can be traced back to the boundary conditions which give rise to the present expansion of the universe. It has been remarked that if we live in a universe in which contraction follows expansion periodically, then the universe itself is clearly nature's largest clock.

Arrow of Time

There are, of course, several arrows of time. The thermodynamic arrow is the first. The biological arrow is the second, and points towards age and death, which are at least in principle physico-chemical phenomena. It also points (broadly speaking) in the direction of the increases in knowledge of intelligent beings—a less obviously physico-chemical notion; but one which is a reminder of the operation of Maxwell's demon. By virtue of his knowledge he was able to reduce the entropy of a physical system, and this is a notion with which we have become familiar in the meantime. The demon has not been killed; he has been absorbed, has been given a label, and is now classified as an information-gathering mechanism. Biologists do, of course, study energy balances and energy transformations. Occasionally they even venture into estimates of entropy changes in living things. How soon can definitive relations be established between such changes and the processes of learning, ageing, and so on ?

The cosmological arrow of time is the third arrow, and points in the direction of an expanding universe. How does it come about that these three arrows all point in the same direction ? This empirical fact will surely remain a subject of speculation for a long time to come. Indeed, it may never be elucidated.

Much has also been written recently about the thermodynamic equations which should be used by an observer who is describing a system moving relative to him. This "special relativistic thermodynamics" is somewhat remote from experiment at present and there is no consensus of opinion as to how it should be formulated[24]. It leads to the equally uncharted area of relativistic statistical mechanics. Are the probabilities of statistical mechanics, are entropy and temperature, Lorentz-invariant ? The answers are not known with certainty.

There is also no very clear understanding yet of the best way of using thermodynamics to elucidate the key properties of living matter. It seems that thermodynamics should have a greater contribution to make than has so far been possible, but there are clearly several major conceptual difficulties to be overcome first (ref. 25 and references cited there). This is another speculative but potentially important area in which further work should be encouraged.

Lastly, it must not be forgotten that thermodynamics has also been turning in upon itself, and its foundations are in the process of being axiomatized[26]. It was possible to answer with a clear "No" the question "Is thermodynamics an axiomatic discipline ? " in the early 1960s[27]. It looks as if the answer may be different in the 1970s. Whereas Carathéodory was able to reach an empirical temperature and an empirical entropy without the notion of heat, it is now possible to reach the empirical entropy without even first introducing temperature (Falk and Jung), and possibly even without requiring the notions of adiabatic processes and of equilibrium states (Giles).

The notion of a negative temperature is no longer new, but it warrants a few remarks. It can be understood in terms of systems with a finite number of energy levels (more precisely with energy levels which have a finite upper bound). If the highest level is occupied, while the remaining levels are empty, the temperature may be regarded as -0 and the entropy as zero. As particles drop back, the system loses energy but gains entropy until, for a uniform distribution of particles over quantum states, the temperature is $\pm\infty$, and the entropy has its maximum value. It is most convenient to plot the entropy of a system in a fixed configuration (volume fixed, magnetic field fixed, and so on) against the variable $\tau = -1/T$ (Fig. 1). Then it is seen that as energy is pumped into the systems the temperature T suffers rather strange changes, whereas τ behaves quite smoothly:

$$T: 0, \ldots, +\infty, -\infty, \ldots, -0$$

$$\tau: -\infty, \ldots, 0, \ldots, +\infty$$

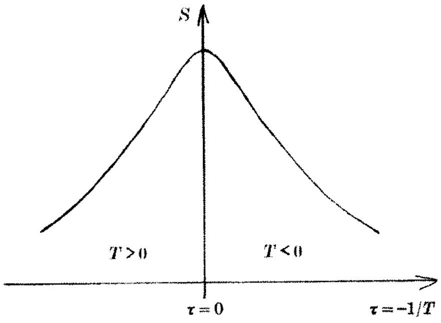


Fig. 1. The entropy of a system plotted in a fixed configuration as explained in the text.

Communicating Thermodynamics

A great many people are interested in thermodynamics. It enters into physics, chemistry, biology, engineering and casts its shadow over linguistics, economics, philosophy and theology. Why should this be ? The reason is twofold: First, the subject is general, abstract and independent of models. For example, any statistical mechanical model must agree with the thermodynamic relations. Yet, second, the subject has a very specific property, and that is the one way character of the entropy. These two observations make sense only if this one way character expresses a rather profound truth. What is this truth ? Just as the hundreds of books of thermodynamics look so different, so the answer to this question can differ widely. Perhaps this truth merely expresses the property of increasing randomness when a statistical system is left to itself in a situation in which the effect of long range forces can be neglected.

The wide interest in thermodynamics and also its abstract nature lead to problems of communication. Should thermodynamics for engineers be different from thermodynamics for physicists ? Can they understand each other's language ? What is the "core thermodynamics" to be taught to everyone ? Problems of this type will occupy us for some time.

Travelling Waves as Frequency Analysers in the Cochlea

by
GEORG VON BÉKÉSY
Laboratory of Sensory Sciences,
University of Hawaii,
1993 East-West Road,
Honolulu, Hawaii 96822

The human ear can detect a pitch change of 10 per cent of a pure tone in a time interval of two cycles. The inner ear, representing the combination of a mechanical and a nervous system, therefore seems to be superior to filters based on pure resonance and energy accumulation.

THE performances of our sense organs are impressive even by today's standards of technology. The methods used in nature are in general different from those an engineer would use and are often unexpected. In hearing, it is the combination of a fast acting but rough frequency analysis by travelling waves with the inhibitory processes of the nervous system which produces a unique system superior in performance to the filters used in communication engineering.

Definition of Resonance and Travelling Waves

Fig. 1*A* shows a pendulum which is attached to an oscillating support. This is the representation of a simple resonance system. If the resonant frequency of the pendulum coincides with the driving frequency of the oscillations of the support, the amplitude of the pendulum will constantly increase. It accumulates energy. When the oscillations of the support stop, the energy of the oscillation of the pendulum can only decrease if friction is present. This system is called a true resonance system. The resonance curve is symmetrical when we plot the amplitudes of the pendulum versus the frequency deviations (plus and minus) from the resonant frequency.

If we have a set of such pendulums with different lengths and different resonant frequencies, moved by the same oscillating support, according to drawing *B*, we obtain a travelling wave when two neighbouring pendulums are coupled by a small weight between the pendulums. In this case the movements of the pendulums no longer represent true resonance. The resonance curve is no longer symmetrical around the resonant frequency of one specific pendulum. If the oscillations of the support stop, a pendulum loses its energy in two different ways. First, by the friction similar to energy lost in the case of drawing *A* and, second, by a shift of the energy from one pendulum to its neighbouring pendulum. It is convenient to call this lateral energy flow to the sides a travelling wave. If the row of pendulums is long enough, the amplitude of one specific pendulum will decrease even if there are no frictional forces present because the energy flows away.

If the mass of the coupling ball between two pendulums is small, or the coupling balls are placed very close to a supporting point, the lateral energy flow is relatively small and we have a combination of true resonance and a travelling wave. Whether or not along the cochlea we have true resonance points or a travelling wave is therefore determined by how much coupling exists between the adjacent sections along the basilar membrane.

If we could separate the basilar membrane into small strips perpendicular to the longitudinal axis, we might approach the situation of true resonance on the condition that we neglect the coupling produced by the friction of the perilymph. The question as to whether a true resonance or a travelling wave dominates the vibrations in the basilar membrane depends on the numerical value of the coupling. The statement of the numerical value of the coupling is therefore the basis for discussion of travelling waves.

If we observe a set of pendulums with a small amount of coupling between them, it is surprising how long it takes for the pendulum to establish their final oscillatory amplitudes after the support starts to oscillate. When the oscillations of the support are suddenly stopped, the decay time is also very long. But if the coupling is increased the lateral flow of energy will start and stop a specific pendulum quite quickly.

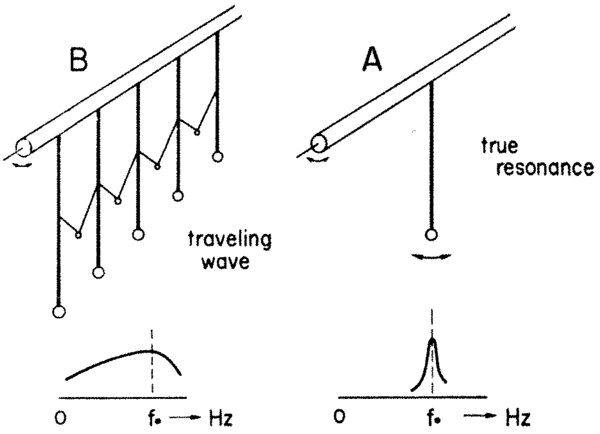

Fig. 1. *A*, A pendulum as a representation of a true resonance system which accumulates energy delivered through oscillations of the suspending point. Below the drawing is a schematic amplitude response for different frequencies of the oscillations of the suspension. *B*, Several pendulums of different resonant frequencies driven simultaneously. The coupling between the pendulums is represented by small balls between neighbouring pendulums. The energy flows constantly from the shorter pendulums to the longer ones.

To find out which type of energy dissipation is dominant in the cochlea of the human temporal bone preparation or an anaesthetized animal, I used stroboscopic illumination projected from a slit lamp made from a microscope. The microscope ocular was replaced by a mercury arc and the slit light beam thus produced was similar to that used in ophthalmology, but with a diameter of 0·01 mm. Using such a slit illumination, some of the corners of the cell membranes appear as bright points. Observing these points with another microscope with a magnification of × 150, it is easy to judge the vibration amplitude of the basilar membrane, Reissner's membrane and the organ of Corti.

With such an apparatus, if the sound to the ear is switched off, in the case of true resonance, the vibration amplitudes should collapse locally, but if a travelling wave is present, then in the stroboscopic illumination the vibrations should be observed to move away laterally. We can learn to discriminate between the two phenomena by observing the vibrations of the membrane of a telephone which is switched off suddenly and comparing it with the vibrations of the basilar membrane. It was found for different animals that the vibrations were damped by a lateral flow of the energy as the main feature.

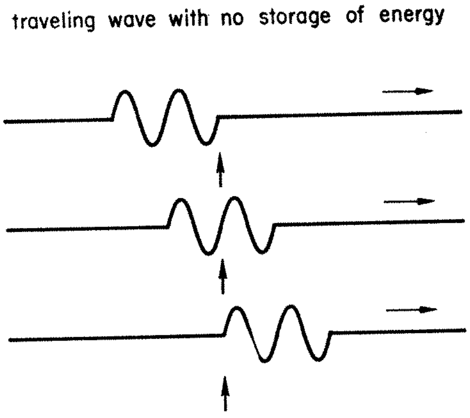

Fig. 2. Two sinusoidal oscillations moving along a rope at different time intervals. There is practically no onset and offset phenomenon at a certain point of the rope, because the rope does not accumulate energy: it just transmits it.

Why transients and storage of energy are avoided in a travelling wave can be seen from Fig. 2. A travelling wave of two cycles initiated at the left will move to the right with practically no accumulation of energy in a system like a rope, a water surface, a longitudinal membrane and so on. If we look at a certain fixed point, the moment a travelling wave reaches that point the oscillation will be instantaneously at full amplitude, and after two cycles have passed that point the oscillations will stop. If the travelling wave is absorbed at the right of the system there will be no reflexions. In the cochlea this absorption is accomplished by the helicotrema.

If the transmitting line is not uniform, during the movement of the waves the amplitude of the oscillations will for every frequency reach a maximum at a different place. This scheme fits perfectly with the anatomical structure of the inner ear, especially the basilar membrane.

Possible Mathematical Vibration Patterns of the Basilar Membrane

The many theories of hearing can be classified in four main groups: (1) the resonance; (2) the travelling wave; (3) the standing wave; and (4) the telephone theories of hearing. All four have proposed different types of vibration patterns of the basilar membrane as the main feature. For almost a century they seem to have been regarded as completely independent theories. But it was shown earlier that in a small experimental model of the size of the normal human basilar membrane, there is no difficulty in going from one type of vibration pattern continuously to another type, changing only two parameters; the volume elasticity of the basilar membrane and the coupling between neighbouring sections. Mathematically speaking, they all belong to the same equation, the difference between them arising only from the assumed numerical values of the basilar membrane[1].

The mathematical treatment of the cochlea is unfortunately to a large degree a hydrodynamic problem. To avoid some of the difficulties I always assumed a laminar flow of the fluid. This assumption later turned out to be a possibility, but it is probably not a stable mode of flow. The introduction of viscosity can change the equations significantly, and I was often reminded of the experiments of Reynold where the laminar flow in a tube with increasing speed suddenly became turbulent for reasons which were mathematically hard to define. Leaving out viscosity and the boundary conditions, it was in most cases not possible to exclude a hydrodynamic paradox[2]. Modern computer techniques should overcome this difficulty.

Longitudinal Stress in the Organ of Corti as a Mechanical Sharpening Device

Because, during evolution, the curvature of the cochlea has become continually greater, one wonders whether the curvature produces a mechanical sharpening effect. There are two principal possibilities: (1) that the curved basilar membrane itself produces a sharpening effect and (2) that the organ of Corti sharpens the discrimination, because the organ of Corti can be looked upon as an elastic transmission system between the basilar membrane and the tip of the hair cells under the tectorial membrane. Such an elastic system could act as a sort of filter.

To test the first possibility, the organ of Corti was brushed off from the basilar membrane with the use of a specially made thin brush. The basilar membrane is stiff enough for there to be no difficulty in peeling off the whole organ of Corti from the membrane. Observation, under stroboscopic illumination, of the vibrations of a cochlear partition and the basilar membrane, without the organ of Corti, showed no specific difference as compared with the organ of Corti intact.

The vibration pattern of the organ of Corti is shown in Fig. 3 (ref. 3). A new phenomenon was that the direction of the vibrations of the hair cells changes along the basilar membrane, mainly as a consequence of the curvature, and this might produce a sharpening effect in the localization. If the hair cells are able to detect such a change in the vibration direction, because the inner and outer hair cells are stimulated in opposite phase, there is a possibility of neural inhibition which might be sensitive to a change in direction. In my opinion the movement of the organ of Corti sandwiched between the basilar membrane and the tectorial membrane is an interesting problem if we take curvature into consideration. It is the same type of vibration calculated by Huxley[4] for the basilar membrane. Direct observations have, however, failed to confirm the local energy accumulation in the organ of Corti or the basilar membrane which should result from this form of vibration.

These observations were carried out with a stroboscopic illumination of a special type, an alternating red and green flash, which enabled measurement not only of the vibration amplitudes but also the phase of the vibrations. Using a slit microscope with underwater surgery in a slowly moving fluid, it was easy to do precise work.

These measurements have been confirmed recently with different methods by Johnstone and Boyle[5] and Tonndorf and Khauna[6]. The electrophysiological recordings of Tasaki[7], Katsuki[8] and Simmons and Linehan[9], and

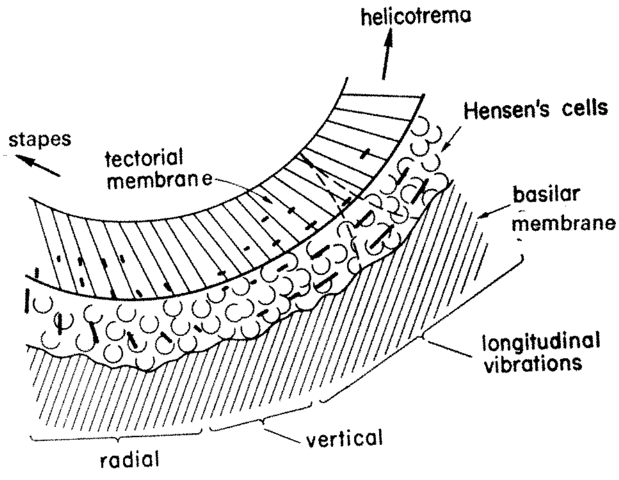

Fig. 3. The curvature in the cochlea might produce a sharpening effect of a mechanical type, because there is a change of the direction of the vibrations in the organ of Corti (taken from G. von B., *J. Acoust. Soc. Amer.*, **25**, 770; 1953).

measurements by Galambos and Davis[10] also confirmed response curves in agreement with travelling waves. They show an asymmetric response as shown in the lower left corner of Fig. 1.

Model Experiments

In physiology it is assumed that a model is an enlarged or reduced replica of a certain system and, because not every item can be completely duplicated, something is automatically wrong. I have used modelling techniques rather differently. In a system like the cochlea there are so many variables that it would be impossible to measure them all. The question is therefore which is the variable of importance for a certain phenomenon? Modelling techniques provide us with the possibility of leaving out certain structures so that we can study the variables which determine the particular phenomenon in which we are interested[11]. For the cochlea it was determined in this manner that volume elasticity of the basilar membrane is an essential variable and therefore it was the one that was measured first in the human cochlea. The height of the cochlear channel, the width of the basilar membrane, and the length of the fluid column between the basilar membrane and the stapes foot plate would make only small changes. The same holds also for the curvature of the basilar membrane, but not for the curvature of the organ of Corti. The enlarged model of a cochlea provided a chance to replace the hearing nerves with the nerves of the skin.

Several types of models were made: straight ones for the underarm and curved ones representing the upper coil of the human cochlea with the basilar membrane circling around the helicotrema (Fig. 4). The travelling waves were about the same in the curved and in the straight model. The curved model had an outside diameter of about 8 inches. It was placed vertically on a table and adjusted so that the whole model touched the abdominal wall of a standing person. A change in the frequency moved the maximum of the vibrations. The sharpening effect[12] of the localization sensation is a surprising phenomenon because the vibrations can only be felt in a small section of the membrane. Because the sharpening effect of the organ of Corti is omitted, this model can be further improved.

Four Base-specific Nucleoside 5'-Triphosphatases in the Subviral Core of Reovirus

by

A. M. KAPULER
N. MENDELSOHN
H. KLETT
G. ACS

Institute of Muscle Disease, Inc.,
515 East 71st Street,
New York, New York 10021

By virtue of their capacity to hydrolyse the substrates of RNA polymerase, the nucleotide phosphohydrolases present in the subviral core may serve to regulate transcription. They may also have a phosphodiesterase function concerned with the processing of polynucleotide chains.

Studying the life cycle of a virus frequently provides a way of discovering and understanding biochemically important cell functions. This has been particularly so for the DNA and RNA bacteriophages of *Escherichia coli*. The discoveries that polio virus RNA codes for polypeptide precursors of functional proteins[1], and that *Vaccinia* virus[2] and reovirus[3,4] assemble their mRNA synthesizing enzymes within the mature virion, illustrate that this is also true for animal virus cell systems.

We have studied the reovirus transcriptase in an attempt to develop an *in vitro* transcription–translation system amenable to experiments relating to interferon. While characterizing this RNA polymerase, which can be isolated from infected L cells in subviral cores, we observed that a triphosphate-generating system is necessary for extensive RNA synthesis. This article describes four enzyme activities localized within the virion which are responsible for hydrolysing polymerase substrates to di-

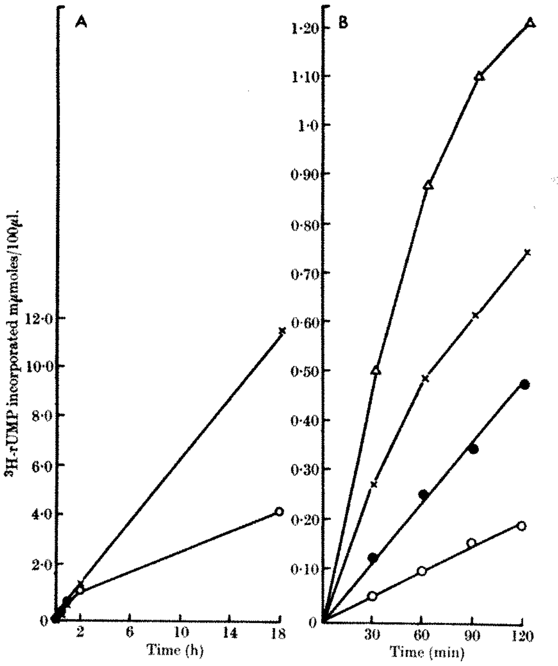

Fig. 1. Kinetics of RNA synthesis: *A*, Requirement for an rNTP generating system for linearity. Two reactions, each twice normal scale, were prepared in standard conditions and incubated at 37° C for 18 h. Aliquots of 40 μl. were withdrawn and analysed. Both reactions included 0·60 units of SVP fraction 4, and one reaction (×) also contained 5 μg of pyruvate kinase (Boehringer) and 1 μmole of sodium phosphoenolpyruvate. *B*, Effect of different amounts of enzyme on linearity. Four reactions, each twice normal scale, were prepared in standard conditions and synthesis was followed as described. SVP fraction 4 was added in the following amounts: ○, 0·13 units; ●, 0·26 units; ×, 0·39 units; △, 0·52 units.

phosphates. The activities are functionally separate from that of the polymerase and are probably associated with a single protein. They may be involved in processing mRNA, regulating the transcriptase or reorganizing the ten chromosomes[5-9] into the reovirion.

Table 1. COMPARISONS OF THE REOVIRUS SUBVIRAL PARTICLE RNA POLYMERASE AND NTPASES

	RNA polymerase	NTPases
Substrate requirement	rCTP, rGTP, rUTP, rATP necessary together; no mononucleotide polymerization	Each rNTP hydrolysed singly, independently (Figs. 2 and 4)
Substrate specificity	Only rNTP is polymerized; dATP and 8-bromo-GTP* are not substrates (Table 3)	rNTP, dNTP and rNTP analogues including 8-bromo-GTP, are hydrolysed; neither rNDP nor rNMP are substrates (Table 3)
Monovalent cation dependence	Strong dependence on M^+; 12-fold stimulation by 0·25 M K^+; $K^+ \simeq NH_4^+ > Na^+$	Inhibited 30–50 per cent by 0·25 M K^+ or Na^+ †
Thermostability	$t_{1/2}$ (Fig. 5): 60° C, 9 min; 70° C, <1 min	rATPase (Fig. 5): $t_{1/2}$: 60° C, >15 min; 70° C, 8 min

* 8-bromo-GTP is an rGTP analogue with normal hydrogen bonding sites but an abnormal conformation (*syn* rather than *anti*: A. M. K. and E. Reich, in preparation; refs. 22, 23, 24).

† rGTPase and rCTPase assays were performed in standard conditions with SVP fractions 4. Inhibition of both activities by potassium or sodium acetate followed identical dose-response curves. For example, rGTPase was reduced by 0·10, 0·25 and 0·50 M potassium acetate to 93, 67 and 27 per cent of control, respectively.

Enzymatic Activities associated with Reovirus Subviral Particles

Twelve to fourteen hours after infection, a template-bound RNA polymerase can be purified approximately 200-fold from the cellular cytoplasmic matrix (ref. 10 and G. A., D. Levin, N. M., M. Schonberg, H. K., S. Silverstein and A. M. K., unpublished results). As can be seen under the electron microscope, the purified enzyme is a component of the subviral core, and the isolation procedure involves stripping off the outer capsomeres from cell-associated virus with sodium dodecyl sulphate and chymotrypsin. The subviral particles (SVP) have a density in CsCl of 1·43–1·45 g/ml., whereas that of the mature virus is 1·36–1·38 g/ml. (refs. 2 and 3). The RNA product is single-stranded, non-self-complementary, sedimentable in sucrose gradients with coefficients of 15S, 19S and 25S and specific for the ten chromosomes of reovirus. As judged by its inability to degrade poly rC

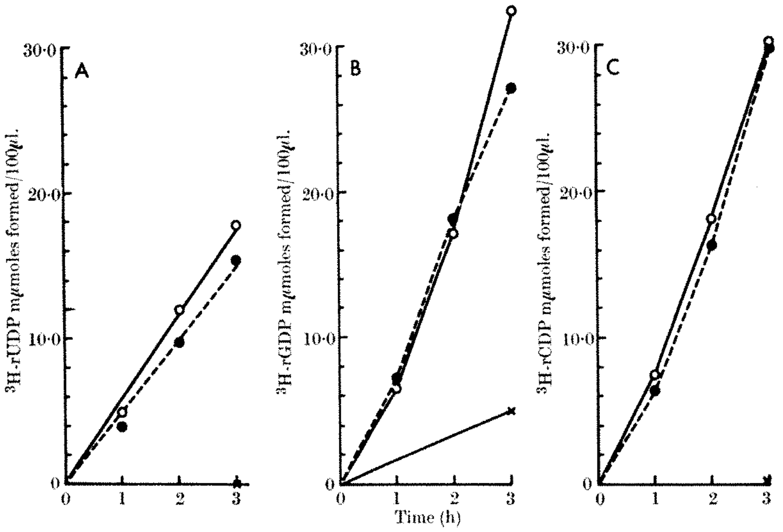

Fig. 2. Kinetics of hydrolysis of rUTP, rGTP and rCTP by subviral particles. Reaction mixtures, prepared in standard conditions in 100 μl. volumes, contained (unless otherwise indicated) 1·2 μg (0·3 polymerase units) of SVP fraction 3 and the following substrates: *A*, ○—○, ^{3}H-rUTP, 100 nmoles (specific activity 7,500 c.p.m./nmole). ● - - - ●, ^{3}H-rUTP, 100 nmoles; rGTP, rCTP, rATP, 200 nmoles each. ×—×, ^{3}H-rUTP, 100 nmoles, no enzyme. *B*, ○—○, ^{3}H-rGTP, 100 nmoles (specific activity 35,000 c.p.m./nmole). ● - - - ●, ^{3}H-rGTP, 100 nmoles; rCTP, rATP, rUTP, 200 nmoles each. ×—×, ^{3}H-rGTP, 100 nmoles, no enzyme. *C*, ○—○, ^{3}H-rCTP, 100 nmoles (specific activity 13,000 c.p.m./nmole). ● - - - ●, ^{3}H-rCTP, 100 nmoles; rATP, rUTP, rGTP, 200 nmoles each. ×—×, ^{3}H-rCTP, 100 nmoles, no enzyme.

Table 2. 8-BROMO-GTP AND dATP AS POTENTIAL SUBSTRATES FOR THE REOVIRUS POLYMERASE

Substrates (nmoles/reaction):	nmoles ^{3}H-rUMP incorporated 1	2
rATP (200), rCTP (200), rUTP (200) and:		
rGTP (20)	0·30	
rGTP (200)	0·38	
bromo GTP (140)	< 0·003	
rGTP (20), bromo-GTP (140)	0·26	
rCTP (200), rUTP (200), rGTP (200) and:		
rATP (50)		0·18
rATP (200)		0·34
dATP (200)		< 0·001
rATP (50), dATP (100)		0·15

Reactions were performed in standard conditions. Series 1: 0·36 units of SVP fraction 3 and ^{3}H-rUTP (specific activity 26, 300 c.p.m./nmole) per reaction. Series 2: 0·20 units of SVP fraction 4 and ^{3}H-rUTP (specific activity 15,000 c.p.m./nmole) per reaction; incubated for 60 min. The ability of bromo-GTP to replace rGTP was further assessed by measuring the dilution of α-^{32}P-rGTP relative to ^{3}H-rCTP in a series of reactions containing increasing amounts of bromo-GTP and fixed amounts of rGTP. In these conditions, bromo-GTP was incorporated into RNA at less than one five-hundredth the rate of rGTP.

and 28S L cell rRNA, there is no detectable ribonuclease activity associated with the polymerase. The polymerase assay and the definitions of enzyme activity are described in the legend to Fig. 1.

The reovirus polymerase requires a ribonucleoside triphosphate (rNTP) generating system such as phosphoenolpyruvate and pyruvate kinase for continued linear synthesis of RNA (Fig. 1*A*). In the absence of the kinase system, the rate of RNA synthesis decreases after 2 h whereas replenishment of substrates *in situ* permits linear synthesis for 18 h. When increasing amounts of enzyme are supplied to a series of parallel reactions, the initial velocities of RNA synthesis increase proportionately, and concomitantly the duration of linear kinetics decreases (Fig. 1*B*). These observations imply that an activity, present in the polymerase preparations, is degrading one or all of the substrates to their corresponding diphosphates.

The hydrolysis of NTP to diphosphates by SVP or chymotrypsin-activated reovirus was measured using three different techniques: electrophoresis (Fig. 2), thin-layer chromatography (Fig. 3) and colorimetry (Table 2). Reactions were performed in standard polymerase conditions in volumes of 50 or 100 µl. NTP substrates were supplied as indicated in the legends to the tables and figures, and specific radioactivities are given where appropriate. The incubation was for 60 min at 37° C.

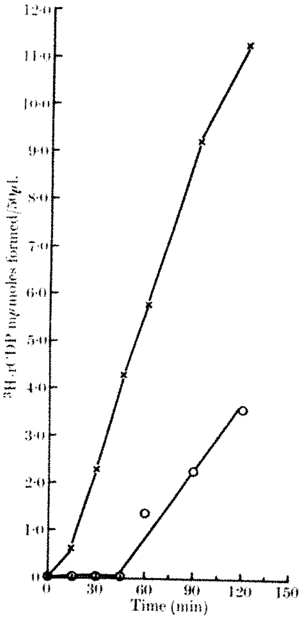

Fig. 3. Latency of rCTPase activity in the reovirion; activation by chymotrypsin. Two reactions, half normal scale, were prepared in standard conditions. Both included 2·4 μg of reovirus (0·12 polymerase units) and 100 nmoles of ^{3}H-CTP (20,000 c.p.m./nmole). ×—×, Plus 5 μg of chymotrypsin; ○—○, no chymotrypsin.

rATP, rUTP, rCTP and rGTP were all substrates for the SVP fractions 3 and 4; the results for the last three are found in Fig. 2. At equal concentrations, rATP was hydrolysed at approximately twice the rate of rCTP and rGTP, which in turn were hydrolysed 1·8–2·4 times more rapidly than rUTP. The hydrolysis of rCTP, taken as representative of the four polymerase substrates, was a linear function of enzyme concentration. In standard conditions, 2·6, 5·8, 9·0, 11·0 and 15·5 nmoles of inorganic phosphate were released in the presence of 2·5, 6·0, 10·0, 12·0 and 18·0 µg of SVP fraction 4, respectively.

The stoichiometry of the reaction was measured with rATP as substrate. Mono, di and triphosphates were measured radioisotopically after separation by thin-layer chromatography; inorganic phosphate was determined colorimetrically. In a standard reaction, 16·8 nmoles of rADP were formed and 13·6 nmoles of orthophosphate released. No monophosphate was produced in the reaction.

Demonstration of NTPase Activity in the Mature Virion

Reovirus was isolated from L cells by standard procedures[11,12] and characterized initially with regard to its RNA polymerase activity. The RNA polymerase of the virus was manifest only after chymotrypsin treatment, in confirmation of the observation of Shatkin and Sipe[3]. Thus, in standard conditions, 1·3 nmoles of rUMP were polymerized in 2 h by 4·6 µg of chymotrypsin-activated virus, but less than 0·020 nmoles were polymerized in a comparable reaction containing untreated virus. Our virus preparation also had the same requirement as the SVP enzyme (Fig. 1*A*) for an energy-generating system in order to synthesize RNA with linear kinetics.

The triphosphate hydrolase activities of the virion have latency characteristics similar to those of the polymerase. There is no rCTPase activity in the virion during 45 min at 37° C and then a spontaneous—probably heat-induced—activity is observed (heat activation of virion polymerase has been reported)[4]. Addition of chymotrypsin to the reaction gives an immediate rCTPase activity (Fig. 3). The virion NTPases, after pretreatment of the virus with chymotrypsin, can hydrolyse rCTP, rATP, rUTP and rGTP to their corresponding diphosphates. As observed for the SVP hydrolases, the chymotrypsin-treated virion degrades rATP twice as rapidly as rGTP and rCTP (Fig. 4). Hydrolysis of rUTP is at 0·4–0·6 the rate of rGTP and rCTP, in comparable conditions. Thus the mature virion, as well as subviral particles from infected cells, possesses four NTPase activities.

Table 3. SUBSTRATE SPECIFICITY OF THE SVP NTPases

Substrates	nmoles Pi formed /h/reaction 1	2
rAMP	< 1·0	
rGMP	< 1·0	
rUMP	< 1·0	
rCMP	< 1·0	
rADP	1·3	
rGDP	1·1	
rUDP	< 1·0	
rCDP	< 1·0	
dATP		19·0
dGTP		13·8
dUTP		12·1
dCTP		10·0
rATP	29·2	36·6
rGTP	13·1	15·8
rUTP	5·7	6·9
rCTP	11·7	16·2
8-Bromo-GTP		6·9
8-Oxo-GTP		4·4
Formycin triphosphate		33·0
5-Bromo-CTP		11·1
5-Fluoro-UTP		5·8
Tubercidin triphosphate		12·5

In these experiments, only 5′-phosphoryl compounds were studied. Reactions were performed in standard conditions; those in series 1 and 2 received 0·05 and 0·12 μg, respectively, of two different preparations of SVP fraction 4. 100 nmoles of each compound were provided per reaction.

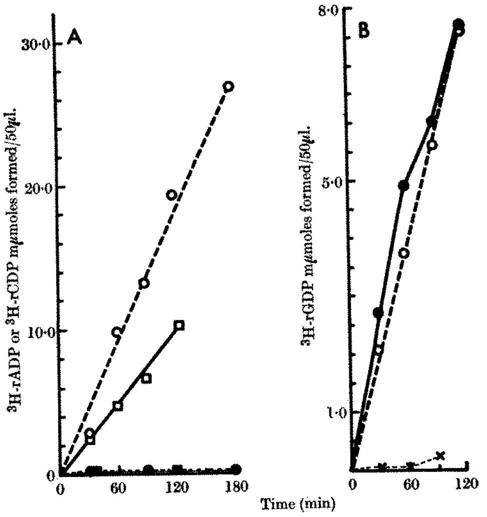

Fig. 4. Kinetics of hydrolysis of rATP, rCTP and GTP by chymotrypsin-activated reovirus. Reactions were prepared, half normal scale, in standard conditions, and (unless otherwise indicated) included 2·4 μg reovirus (0·12 polymerase units) which was activated by preincubation of 24 μg virus with 50 μg chymotrypsin for 10 min at 37° C. *A*, ○ --- ○, ^{3}H-rATP, 100 nmoles (specific activity 12,500 c.p.m./nmole); ● --- ●, ^{3}H-rATP, 100 nmoles, no enzyme. □—□, ^{3}H-rCTP, 100 nmoles (specific activity 15,000 c.p.m./nmole); ■—■, ^{3}H-rCTP, 100 nmoles, no enzyme. *B*, ○ --- ○, ^{3}H-rGTP, 100 nmoles (specific activity 11,200 c.p.m./nmole). ●—●, ^{3}H-rGTP, 100 nmoles; rATP and rUTP, 100 nmoles each. × --- ×, ^{3}H-rGTP, 100 nmoles, no enzyme. Assays were performed as described in the legend to Fig. 3.

The relative rates of hydrolysis of rCTP, rGTP and rATP by the virion NTPases (in nmoles of inorganic phosphate/h/unit of RNA polymerase) were 22·5, 15·0 and 75·0, respectively. In one preparation of SVP fraction 3 (specific activity 140 polymerase units/mg) they were 23·0, 16·0 and 87·0. In general, however, the ratios of NTPases to polymerase were 5–10-fold greater in the SVP preparations.

Analogous to the auxiliary activities of the *E. coli* DNA polymerase[13], the four rNTPase activities may correspond to four base-specific activities of the SVP polymerase not directly related to RNA synthesis. The polymerase and triphosphate hydrolases can, however, be distinguished by several criteria summarized in Table 1.

Characteristics of NTPases

rCTPase is strongly inhibited by inorganic pyrophosphate with a stoichiometry suggesting that the inhibition is achieved indirectly by removal of divalent cations. Surprisingly, inorganic phosphate inhibits neither the polymerase nor the rCTPase (Table 4). Deletion of Mg^{2+} from the rCTPase reaction inhibits hydrolysis by 55 per cent; replacement of Mg^{2+} by 1·5 mM $MnCl_2$ stimulates hydrolysis by 43 per cent beyond the unsupplemented level. In comparison, the polymerase has a more stringent divalent ion requirement, deletion of Mg^{2+} reducing the rate of polymerization by 95 per cent (G. A., D. Levin, N. M., M. Schonberg, H. K., S. Silverstein and A. M. K., unpublished results). Addition of 370 and 1,250 nmoles of EDTA to standard rATPase assays reduces hydrolysis by 80·5 and 90·0 per cent, respectively.

Table 4. EFFECT OF PHOSPHATE (Pi) AND PYROPHOSPHATE (PPi) ON THE VIRION POLYMERASE AND rCTPase ACTIVITIES

System	nmoles ^{3}H-rCDP formed (per cent of control)	nmoles ^{3}H-rUMP incorporated (per cent of control)
Control	100	100
Minus enzyme	2	5
+ Pi 2×10^{-3} M	94	92
+ Pi 1×10^{-2} M	83	88
+ PPi 2×10^{-3} M	55	31
+ PPi 1×10^{-2} M	6	5

All reactions included 2·4 μg reovirus (0·12 polymerase units). The enzyme was activated as described in the legend to Fig. 4. Polymerase reactions were performed in standard conditions for 30 min. In the control 0·13 nmoles of ^{3}H-rUMP was polymerized. rCTPase reactions, half normal scale, were incubated for 60 min and contained 100 nmoles of ^{3}H-rCTP (specific activity 15,000 c.p.m./nmole). In the control, 4·7 nmoles of rCDP were formed.

Using electrophoretic or chromatographic assays of NTPase activity, we were able to measure the conversion of a ^{3}H-rNTP to the corresponding diphosphate in the presence of other non-radioactive rNTP. Hydrolysis of rUTP, rGTP and rCTP by the SVP preparation is unaffected by the other three polymerase substrates, even though each is present in twice the amount of the substrate being analysed (Fig. 2). The virion rGTPase had the same insensitivity to other 5′-triphosphates; equal concentrations of rUTP and rATP did not affect the rate of hydrolysis of rGTP (Fig. 4). Pending a more thorough kinetic analysis, the inability of the polymerase substrates to compete with one another for their respective hydrolase activities implies that there are four separate base-specific activities. Whether they are associated with four separate polypeptide chains, or even whether they are all carried in the same subviral particle, is not yet known. It is noteworthy that both rCTPase and rATPase are heat inactivated at the same rate (Fig. 5), for this is evidence for their association with a single protein.

Interrelationship between Hydrolases and Polymerases

Induction of nucleoside triphosphate hydrolases after viral infection usually serves a specific and important function in the life cycle of the virus. The T-even bacteriophages of *E. coli*[14–17] induce virus-specific dCTPases. Because they contain the hydroxymethyl analogue of dCMP in their DNA genomes, the hydrolases function to deplete the pool of unwanted polymerase substrate and enable specific incorporation of the desired residue by the polymerase. These enzymes are remarkably specific, hydrolysing only dCTP to dCMP and inorganic pyrophosphate, and being unable to cleave rCTP[15].

The function of the reovirus-specific NTPases associated with the polymerase in the subviral core is more obscure. Potentially, the rapid hydrolysis of dNTP by the phosphohydrolases provides an explanation for the inhibition of cellular DNA synthesis observed late in reovirus infection[18]. *Vaccinia* virus, the other animal virus that assembles a transcriptase into the mature virion, also has an active rATP hydrolase in the subviral core[2,19].

The functional separation of polymerase and NTPase activities, particularly with regard to substrate specificity and thermostability, would support the notion that the rNTPase activities are not auxiliary activities of the

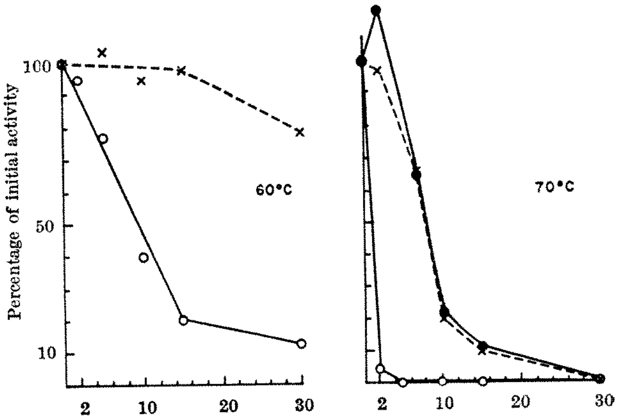

Fig. 5. Heat inactivation of the polymerase and NTPases in the reovirus subviral core. 60° C: 0·43 units of SVP fraction 4 were incubated at 60° C and two aliquots corresponding to 0·030 units each were removed at 2, 5, 10, 15 and 20 min. Polymerase and rNTPase (assayed as described in the legend to Table 3) were measured on these samples in standard conditions and compared with enzyme that was not heated. In the controls, 36·4 nmoles of Pi were released from rATP and 0·026 nmoles of ^{3}H-rUMP polymerized: ○—○, polymerase; × --- ×, rATPase. 70° C: reactions were performed as described except that 0·52 units of SVP fraction 4 were used. In the controls 0·031 nmoles of ^{3}H-rUMP were incorporated into RNA and 29·0 nmoles of rATP and 10·4 nmoles of rCTP were hydrolysed: ○—○, polymerase; × --- ×, rATPase; ●—● rCTPase. With an SVP fraction 3 having a 10-fold lower ratio of rATPase to polymerase, the half times for inactivation at 65° C were 6 and 1·7 min, respectively.

polymerase. Rather, they are activities associated with different proteins bound together in the subviral core. The NTPase activities may well be secondary functions of an enzyme, however, the primary role of which is related to the enzymatic processing of the reovirus mRNAs (such as hydrolysis of the γ-phosphate from RNA chains beginning with pppNp. . .)[20,21]. A more attractive possibility for the primary activity is based on the idea that the biologically relevant leaving group is R–O–PO$_3$ rather than PO$_4$. R could then be a long polyribonucleotide chain, in which case the NTPase would be acting as a phosphodiesterase. In the biology of reovirus replication, such a mechanism might be conceivable if the separate chromosomes were held together by pyrophosphate or tripolyphosphate linkages. Alternatively, the biological role of the NTPases might be to transfer the rNDP moiety to a polynucleotide acceptor, thus providing a mechanism for creating a pyrophosphate linkage between a polynucleotide and a mononucleotide or between two separate polynucleotides, one terminated by pppNp . . . The lack of inhibition of the NTPases by inorganic phosphate is consistent with an alternative function for the enzymes.

In any case, the presence of four hydrolases that destroy polymerase substrates provides a mechanism for regulating polymerase activity. By encapsidating the NTPases in the subviral core, the polymerase activities in the virions maturing late in infection can be reduced, and mRNA synthesis can be severely diminished. Whether the rNTPases are selectively activated at a precise time after infection by an endopeptidase process, analogous to the one found in poliovirus growth[1], remains to be determined.

Polymerase Assay and Purification

Standard assay conditions are 0·1 M Tris-HCl (*p*H 7·9)—0·25 M potassium acetate—0·075 M magnesium acetate with 2×10^{-3} M rATP, rCTP and rGTP, 1×10^{-3} M ^{3}H-rUTP (final specific activity 30–40,000 c.p.m./nmole), and 10^{-4} M dithiothreitol. Reactions are performed for 30 min at 37° C in final volumes of 100 µl. and contain less than 1·5 units of polymerase. They are terminated by addition of 5 per cent trichloroacetic acid, and the polymeric products are trapped on Balston 'GF/A' glass fibre filters. The filters are washed with 7×5 ml. portions of 5 per cent trichloroacetic acid, dried with a heat lamp and counted by standard scintillation methods. One unit of polymerase corresponds to the conversion of 1 nmole of radioactive precursor into acid precipitable material in 30 min at 37° C. Protein was measured by the procedure of Lowry *et al.*[26]. Ribo and deoxyribonucleoside 5′-triphosphates and ribonucleoside 5′-diphosphates were obtained from P–L Laboratories and 5′-monophosphates from Sigma. Tritiated 5′-triphosphates were purchased from Schwartz. Synthesis and characterization of analogue triphosphates or references thereto can be found in the papers of A. M. K. *et al.*[27] and Ward *et al.*[28].

Reovirus transcriptase was purified from infected L cells as follows: Mouse L-929 cells are infected with reovirus, type 3, at a multiplicity of 10–20 p.f.u./cell and incubated in Eagle's[5] spinner medium containing 10 per cent (v/v) foetal calf serum for 12–14 h. The cells are then pelleted by centrifugation and homogenized; the resulting suspension is centrifuged to remove nuclei and unbroken cells. This crude cytoplasmic extract is diluted to 0·5 per cent in sodium dodecyl sulphate and centrifuged at 30,000*g*; a small pellet containing virtually all RNA polymerase activity is recovered. This pellet is treated with chymotrypsin, and the polymerase is pelleted by centrifugation several times to remove polypeptides and chymotrypsin. This resuspended pellet of aggregated subviral particles is SVP fraction 3. This fraction is then made 4 M in urea, layered on a solution of RSB buffer (0·01 M Tris-HCl *p*H 7·4, 0·015 M NaCl, and 0·0015 M MgCl$_2$), 20 per cent in glycerol and 0·1 per cent in 'Brij-35', and centrifuged at 105,000*g* for 2 h in a Spinco 40 rotor. The pellet, resuspended in RSB, is SVP fraction 4. Fractions 3 and 4 have specific activities of 180–250 and 225–325 units/mg, respectively.

The complete virion was isolated from infected L cells as described by Silverstein and Dales[12] and Gomatos[11]. Digestion of the high-speed virus pellet was performed with pancreatic deoxyribonuclease alone, with the omission of both pancreatic ribonuclease A and chymotrypsin. The virus used in our experiments was isolated from a CsCl gradient at a density of 1·36 g/ml. After activation with chymotrypsin, the specific RNA polymerase activity was 50 units/mg.

Assay of NTPases

Separation of nucleotides was carried out by high-voltage paper electrophoresis on Whatman 3 *MM* paper with 0·05 M sodium citrate buffer (*p*H 3·5), for 1–2 h, at 35 V/cm with a water-cooled plate and 5 kV power supply manufactured by Savant Instruments. Aliquots of 5 µl. were removed from enzyme reactions, spotted and dried on top of a mixture of rNMP, rNDP and rNTP (0·1 µmole each) which corresponded to the radioactive rNTP in the reaction. After electrophoresis, the mono, di and triphosphate portions were revealed under ultraviolet light, marked, cut out and counted in a liquid scintillation system. The radioactive rNTPs contained 2–5 per cent of the corresponding rNDP, thus constituting a background which was subtracted from the experimental values.

Thin-layer chromatography was performed with polyethyleneimine-cellulose layers coated on plastic and supplied by Brinkman ('MN polygram cel 300 PEI'). Aliquots of 1 µl. were removed from enzymatic reactions, superimposed and dried on a mixture of mono, di and triphosphates (0·03 µmole each) which corresponded to radioactive rNTP supplied to the reaction. The chromatograms were developed to a height of 12 cm with 1·1, 1·4, 1·4 and 1·7 M LiCl solutions for uridine, adenosine, cytidine and guanosine nucleotides, respectively. In these solvents, the R_f values are, respectively, rUMP, rUDP, rUTP : 0·64, 0·37, 0·17; rAMP, rADP, rATP : 0·54, 0·40, 0·21; rCMP, rCDP, rCTP : 0·61, 0·43, 0·15; rGMP, rGDP, rGTP : 0·46, 0·35, 0·20. After chromatography, the positions of the nucleotides were marked after examination with ultraviolet light, and the di and triphosphates were cut out and counted by liquid scintillation methods. Conversion of rNTP to rNDP was measured by determining the change in the percentage of counts in rNDP relative to rNDP plus rNTP.

For the colorimetric assay of NTPases, the release of inorganic phosphate (P_i) from NTP substrates was monitored[25]. Duplicate reactions were prepared and incubated in parallel: one included enzyme at zero time; the other received enzyme immediately before addition of the acidic molybdate reagent to stop the reaction. The difference between the two reactions measures the enzymatic release of P_i from NTP substrates. All reactions were in final volumes of 50 µl.

We thank Miss Virginia Hamilton for her contributions to the preparation of this manuscript.

Spatial Organization and Interaction of the Two Photosystems in Photosynthesis

by
W. P. WILLIAMS
Biophysics Group,
Physics Department,
Chelsea College,
London

The following is an account of a more generalized model of the interactions in the photosynthetic system. Its advantages and limitations are discussed and the possibility of its extension by the introduction of the concept of an "oxygen-unit" is explored.

THE interaction of the two light reactions, or photosystems, in photosynthesis is most easily explained in terms of the series model of photosynthesis (Fig. 1*a*). According to this, photosystem I (PS I, linked with a CO_2 assimilation system) interacts with photosystem II (PS II, linked with an oxygen evolution system) through an electron transport chain. The model can, however, be misleading. One manifestation of its inadequacy[1] is that it predicts that the addition of an inhibitor such as 3-(4-chlorophenyl)1,1′-dimethylurea (CMU), which has a specific effect on PS II, would necessarily isolate PS I from the oxygen evolution apparatus. The inhibition of oxygen evolution by partial poisoning with CMU should then be independent of wavelength, which is not the case[2]: inhibition of PS II can take place without the concomitant isolation of PS I.

The wavelength dependence of inhibition (compare ref. 1) can readily be explained in terms of additional cross-linkages between the two photosystems allowing the inhibition of PS II without necessitating the isolation of PS I from the oxygen evolution system. Clearly, it would be desirable to design a more formal model detailing these interactions.

If we assume that the basic photosynthetic complex comprises a PS II subunit, a PS I subunit, the electron transport chain joining them and their associated enzyme systems, the necessary extra cross-linkages could be either "intra-unit" or "inter-unit". Additional intra-unit linkages could be visualized, for example, as a number of separately inhibitable electron transport sub-chains diverging from PS II and converging to form the main chain before linking with PS I. If there were a waste of the PS II energy flowing through a sub-chain (which, normally open, was blocked by poisoning) while the PS I energy was redistributed through the remaining unpoisoned subchains, the necessary inhibition without isolation would be achieved. Inter-unit linkages, arranged so as to ensure the localization of the excitation energy of poisoned PS II subunits while allowing the redistribution of the energy absorbed by the corresponding PS I subunits among

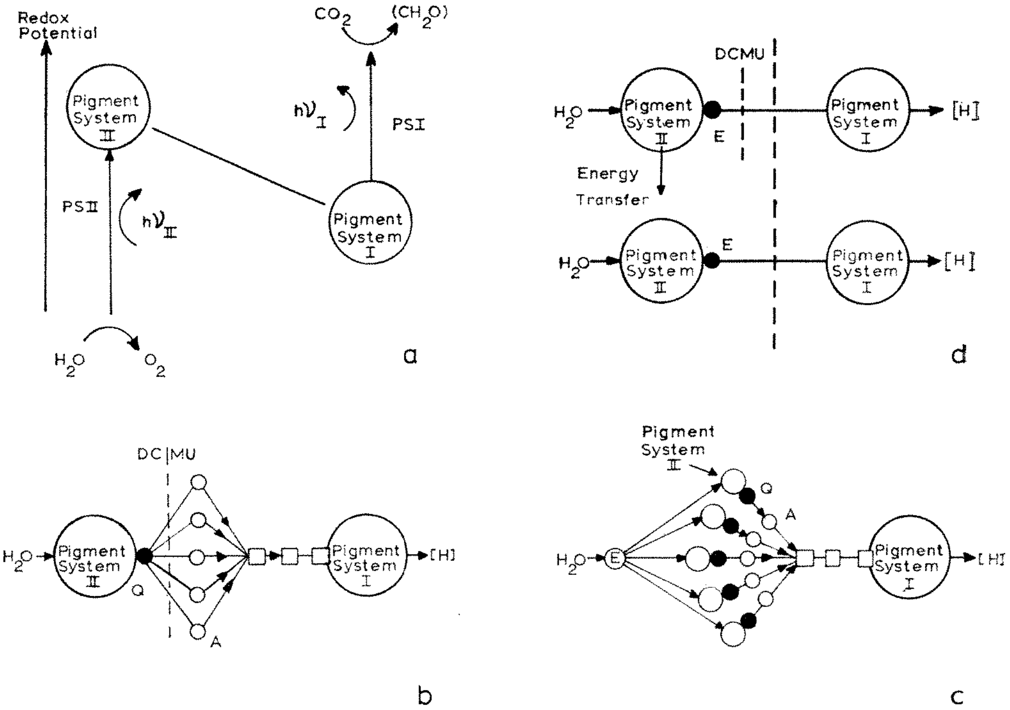

Fig. 1. Current models of the interaction of the two photosystems PS I and PS II: *a*, the simple series model; *b* and *c*, models proposed by Kok *et al.* on the basis of their investigation of the size of the primary oxidant pool available to PS II *d*, model incorporating energy transfer between PS II subunits (postulated by Joliot *et al.*[4]) and an unspecified linkage between neighbouring electron transport chains.

surrounding unpoisoned units, might also be invoked. Kok *et al.*[3], as a result of their studies on the size of the primary oxidant pool available to PS II, have proposed two possible models (Figs. 1*b* and *c*) incorporating multiple electron transport sub-chains. Joliot *et al.*[4], on the basis of two lines of evidence—the non-linearity of the relationship between the amounts of oxygen evolved by poisoned chloroplasts in response to a single short saturating flash and continuous illumination, and the linearity of the fluorescence rise curve in the presence of inhibitor—postulated the transfer of excitation energy between neighbouring PS II subunits. Such a transfer process, if correct, must necessarily infer an even more efficient system for the redistribution of the excitation energy of the corresponding PS I subunits, for otherwise poisoning would seem to involve a preferential inhibition of PS I rather than PS II. Fork and Amesz[5] have put forward evidence for energy transfer between PS I subunits. It suggests, however, a transfer efficiency rather similar to that quoted by Joliot for PS II and, as such, does not give an adequate explanation of the inhibition data. A diagrammatic representation of a model incorporating Joliot's postulated energy transfer and an unspecified linkage between neighbouring electron transport chains is given in Fig. 1*d*.

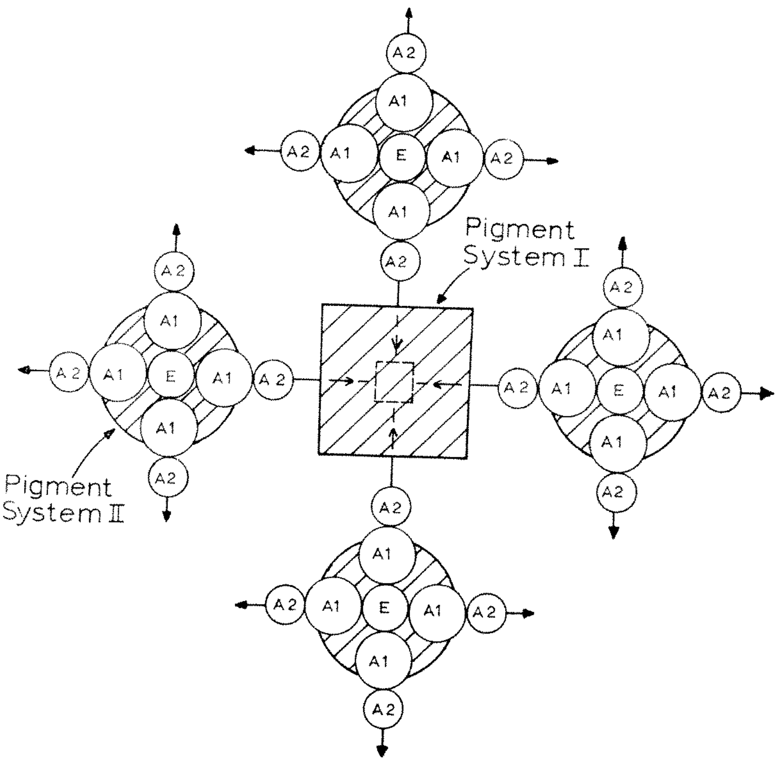

Fig. 2. Repeating unit of the matrix model of photosynthesis. The reaction centre, E, of each PS II subunit is linked to four electron transport sub-chains each of which consists of two primary oxidant molecues, A_1 and A_2. The four sub-chains linking a set of PS II subunits to a given PS I subunit are considered to converge to form the main chain at some early electron transport intermediate such as a cytochrome.

All three models, by incorporating the necessary multiple cross-linkages between the two photosystems, are capable of providing an explanation for the wavelength dependence of inhibition by inhibitors of the CMU type. A further factor which must be taken into account, however, is the extreme sensitivity of photosynthesis to these types of inhibitors. Izawa and Good[6], after investigating the effects of CMU, 3-(3,4-dichlorophenyl)-1,1′-dimethylurea (DCMU) and 'Atrazine' on the rate of the Hill reaction, reported the number of inhibition sites in isolated chloroplasts to be 1 per 2,500 chlorophyll molecules. They consequently postulated the existence of a functional "oxygen-unit" of this size possessing a single inhibition site. Assuming equal amounts of chlorophyll in PS I and PS II, and a PS II subunit size of about 300 chlorophyll molecules, this corresponds to one site per four PS II subunits. Their value is not universally accepted, but an upper limit of one site per PS II subunit seems reasonable. The models discussed so far predict values of from four to five sites per PS II subunit (if the concept of multiple individually inhibitable cross-linkages is to be maintained), down to one site per PS II subunit for the energy transfer model.

Any realistic model of the interactions between the components of the photosynthetic system should contain multiple linkages between the two photosystems (which in the case of "intra-unit" linkages, at least, can be individually inhibited), and at the same time preserve a low ratio of inhibition sites to PS II subunits. Both models proposed by Kok's group fail in that they cannot fulfil both criteria simultaneously. The energy transfer model succeeds, but only at the cost of introducing the added assumption of a system of undefined linkages between electron transport chains. I wish to outline here a new type of model which fulfils both these criteria and which may offer a deeper insight into the photosynthetic process.

The Matrix Model of Photosynthesis

The proposed new model takes into account both the approximate pool size of primary oxidants, as calculated by Kok *et al.*, and the necessity of a low ratio of inhibition sites to PS II subunits. The basic unit (Fig. 2) consists of four PS II subunits, each of which has a reaction centre, E, associated with two primary oxidant pools consisting of four molecules each of A_1 and A_2. These oxidant molecules are arranged in the form of four electron transport sub-chains. The latter, joining a set of PS II subunits to a given PS I subunit, are considered to converge into a single chain at one of the early electron transport intermediates—probably a cytochrome.

The repeating units are considered to be interconnected within a matrix embedded in, or on, the faces of the grana membranes of the chloroplast. When viewed as a matrix (Fig. 3) the ratio of PS I to PS II subunits is 1 : 1. The overall stoichiometries of all the components of the photosystems and their electron transport chains are also maintained.

The electron transport sub-chains, which serve as intra-unit linkages in the models proposed by Kok's group, also serve as inter-unit links in the matrix model. The other models could be adapted to explain the wavelength dependence of inhibition only by assuming that the sub-chains could be individually inhibited. According to the matrix model, a single molecule of inhibitor acting at, or close to, the reaction centre can be considered to inhibit a group of four sub-chains, giving a ratio of 1 : 1 for inhibition sites to PS II subunits. Thus the twin criteria previously outlined can be simultaneously fulfilled. An inhibition site/PS II subunit ratio of one is still at variance with the findings of Izawa and Good, but even this difference can be reconciled by the introduction of the oxygen-unit concept into the matrix model.

Comparison of Matrix Model with Chloroplast Ultrastructure

Electron microscope studies have revealed the existence of two sets of particles arranged in paracrystalline arrays either on, or embedded inside, the grana membranes of

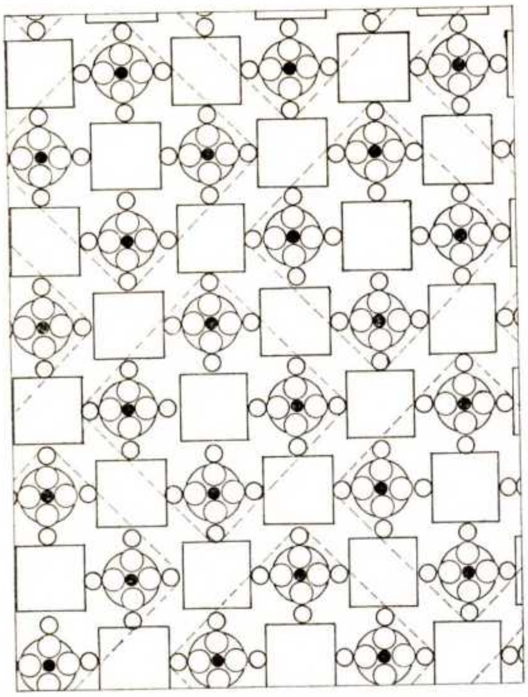

Fig. 3. A set of interconnected repeating units of the type shown in Fig. 2. Individual units are indicated by enclosure by a dashed line. It is not clear, at this stage, whether or not such a division has any structural or functional significance.

the chloroplast. Park and his co-workers[7,8] have favoured the idea that they are located inside the membrane, while Mühlethaler and his co-workers[9] are of the opinion that the two sets are embedded in the outer surfaces of the membrane. Park's group have tentatively identified one set of the particles as units they term quantasomes, which they identify as the physiological equivalent of photosynthetic units. Moudriankis *et al.*[10] confirm the existence of the particles, but believe that they are in fact phosphorylation co-factors. Despite this conflict of opinions on the exact location and function of these arrays, their existence is certain and it is reasonable to assume that they reflect the basic symmetry of the photosynthetic apparatus. A comparison of a schematic diagram of the matrix model with an electron micrograph (after Park and Pfeifhofer[8]) of one of the arrays (Fig. 4) shows that their symmetries are identical.

The Oxygen-unit Concept

The matrix model provides an explanation of the wavelength dependence of inhibition, a role for the primary oxidant pools and a direct link between the ultrastructure of the chloroplast and function of the photosynthetic apparatus, without calling for any changes in the general biochemical properties or overall stoichiometry of this apparatus. It does not explain Izawa and Good's data or throw any light on the possibility of energy transfer between PS II subunits. If, however, the model is extended by the introduction of the concept of an oxygen unit, an explanation of the former—and an alternative explanation of the latter, if one be needed—can be provided.

The oxygen unit as conceived by Izawa and Good was an undefined entity, functionally equivalent to four PS II subunits, with a single inhibition site. I shall define it as the smallest set of mutually adjacent PS II subunits capable of producing oxygen, or a freely diffusible oxygen precursor, in response to a short saturating light flash capable of turning over each subunit once only. The oxygen unit could have two forms. It could correspond to a definite structural unit—the simple form—or to a functional unit consisting of any suitable set of subunits—the generalized form. The behaviour of the two forms is similar and there is no need to distinguish between them at this stage.

To evolve a molecule of oxygen, four electrons must be transferred from water to PS II. Emerson and Arnold[11] showed that a short saturating flash of light can only produce one molecule of oxygen per 2,500 molecules of chlorophyll, that is, one oxygen molecule per four PS II subunits.

Three possible modes of operation of the oxygen evolution system suggest themselves: the product of each PS II subunit could be freely diffusible; the products of two subunits could react with a single molecule of water at a commonly adjacent site, the product so formed being freely diffusible; or the products of four subunits could combine at a single mutually adjacent site to produce a single molecule of oxygen. These three modes of operation are conveniently referred to as A(1), A(2) and A(4). They can be further subdivided depending on the minimum number of functioning subunits needed to drive a set of subunits. The principal possibilities are a single functioning subunit B(1), two subunits B(2) or four subunits B(4). Because the number of functioning subunits cannot exceed the number of subunits in a set, this leads to a total of six operational modes.

The mode normally ascribed to photosynthesis is A(1) B(1), that is, each PS II subunit, acting independently, produces an oxygen precursor with no fixed steric relationship between the sites of energy absorption and oxygen evolution. If, however, we accept the possibility that the operational mode of photosynthesis can be other than the A(1) B(1) mode, two important consequences appear. First, the actual number of inhibition sites need not necessarily coincide with the number calculated from inhibition data. Izawa and Good, assuming a B(1) mode, estimated a ratio of inhibition sites to chlorophyll molecules (before correction for free inhibitor within the chloroplast) corresponding to one site per two subunits. If, however, a B(2) mode is assumed, their data can be

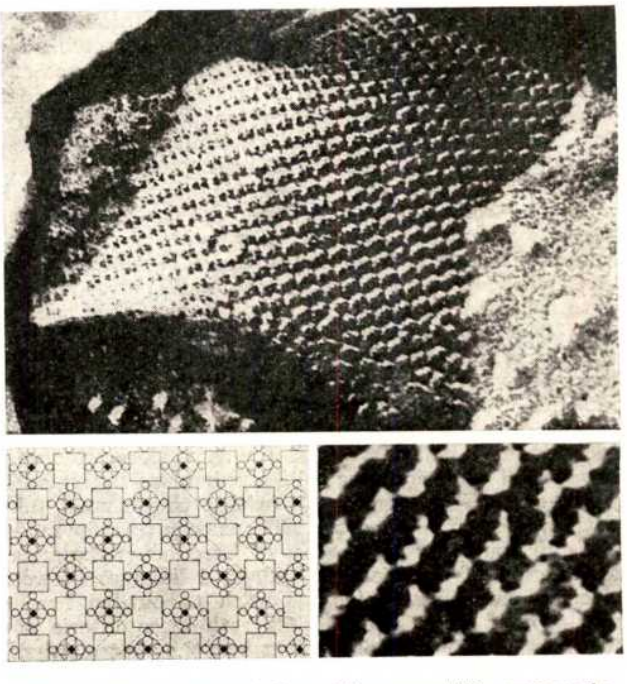

Fig. 4. Electron micrograph of one of the paracrystalline arrays on the surface of a grana membrane exposed by deep etching (after Park and Pfeifhofer[8]). An enlarged section of the array is compared with a section of the matrix model corresponding to a similar area. Their symmetries are identical, suggesting a direct relationship between the ultrastructure of the chloroplast and the matrix model. This, of course, does not necessarily imply an identity between the particles of the array and any specific feature shown in the diagrammatic representation of the model.

re-interpreted as evidence for one site per subunit. Their corrections for the free inhibitor within the chloroplast were also made on the basis of an A(1) B(1) mode and again are open to re-interpretation.

The second consequence is that the oxygen evolution of poisoned chloroplasts in response to a flash need not bear a linear relationship to that evolved by continuous illumination. Such a relationship would be expected only if the number of functioning subunits needed to drive a set of subunits is equal to the number of subunits in the set, that is, for A(4) B(4), A(2) B(2) or A(1) B(1). In these modes the oxygen unit cannot function if any one of its subunits is poisoned. In the other modes, however, a partially poisoned oxygen unit, although unable to respond to a single flash, may respond to continuous light by summing the products of successive turnovers of the remaining functioning units.

A more detailed analysis of these possibilities with the consequent formulae relating the various parameters will be presented elsewhere. Nevertheless, this preliminary analysis should suffice to illustrate how the introduction of the oxygen unit concept into the matrix model—which in itself promises to be a powerful tool—might serve to throw new light on a variety of controversial points in the field of photosynthesis research.

I thank Dr R. B. Park for kindly making available a copy of the electron micrograph of the grana membrane and Dr D. Rosen for his help in the preparation of the manuscript.

New Finds at the Swartkrans Australopithecine Site (*contd*)

Last week Dr C. K. Brain introduced the Swartkrans cave site and described some recent discoveries there. Dr J. T. Robinson now describes two hominid vertebrae which he suggests belonged to a *Paranthropus* individual ; Mr R. J. Clarke, Dr F. Clark Howell and Dr C. K. Brain present evidence for the view that two different hominids once lived at Swartkrans ; and Dr Mary Leakey considers the stone artefacts.

Two New Early Hominid Vertebrae from Swartkrans

Two hominid vertebrae have been recovered by Dr C. K. Brain from the Swartkrans cave site[1]. The specimens were obtained from blocks of breccia which were found lying just outside the site and which had been excavated by lime miners in the early 1930s. It is very likely that all of this material originated from the outer part of the site, and that it was from this breccia that almost all of the early hominid material known from Swartkrans was recovered. Among the specimens found by Dr Brain are a number which seem to belong to *Paranthropus*. The two vertebrae were found in the same block of breccia. Both belonged to adult individuals, possibly the same one, and both are clearly primate. *SK* 3981*a* is a last thoracic vertebra, while *SK* 3981*b* is a last lumbar.

The conclusion that *SK* 3981*a* is the last in the thoracic series is based on two facts: (1) the superior articular facets are typical of thoracic vertebrae but the inferior facets are typical of lumbar vertebrae; (2) complete costal facets are present for the capitula of the ribs and these are situated wholly on the vertebra, partly on the neural arch and partly on the body.

This vertebra is clearly primate and, at this site, primate material is likely to be either cercopithecoid or hominid because no other primate groups are represented in South African Pleistocene sites. The vertebra is, however, not cercopithecoid because it lacks certain cercopithecoid features—in cercopithecoids, for example, the last thoracic vertebra, as judged by the articular facets, is not the last of the rib-bearing vertebrae and therefore has hemifacets as well as a clearly defined costal articular facet on the transverse process. The probability of finding pongid vertebrae in South African sites is very small, but even if it were probable, pongid affinity of this Swartkrans vertebra can be ruled out because it lacks, for example, the relatively small neural canal, low, wide and back-swept neural spines, and the complicated transverse process which are characteristic of pongids.

This vertebra is therefore very probably hominid. Both *Paranthropus* and *Homo erectus* occur in the front cave breccia at Swartkrans, hence the vertebra could belong to either of these. So far as I am aware the last thoracic vertebra is not known in *H. erectus*. Because the postcranial skeleton of the latter seems not to have differed in principle from that of *H. sapiens* so far as is known, it seems not unreasonable to assume that the vertebrae of the two would be rather similar.

The Swartkrans vertebra can be distinguished from the *H. sapiens* homologue by the following features:

(1) It has a relatively long neural spine projecting approximately at right angles to the superior–inferior axis of the vertebra. In modern man the spine is shorter and its total length, measured from the neural canal to the apex, is usually no longer than the anterior–posterior thickness of the centrum. The spine of the fossil specimen is considerably longer than this. (2) The neural canal is relatively large. Although the fossil vertebra is appreciably smaller in overall size than the *H. sapiens* homologue the neural canal is of the same absolute size in the two. Correlated with this is the fact that in lateral view the inferior notch of the fossil specimen is relatively wide and well developed, being of about the absolute size found in modern man although it belongs in a relatively small vertebra. (3) The mammillary process–transverse process

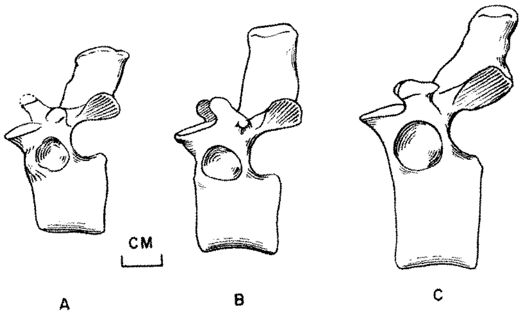

Fig. 1. Last thoracic vertebrae of (*A*), *Australopithecus* (*Sts* 14); (*B*), *Paranthropus* (*SK* 3981*a*); (*C*) *Homo sapiens* in lateral view.

complex is different in the Swartkrans specimen. The mammillary process is relatively well developed but slender, resembling a small transverse process. It is well separated from the transverse process homologue, which is no more than a small tubercle well below the mammillary process.

It is therefore unlikely that the fossil vertebra belongs to *H. erectus*.

One last thoracic vertebra of *Australopithecus africanus* is known from Sterkfontein (*Sts* 14), a description of which, along with that of others from the same vertebral column, is being published elsewhere. This specimen probably came from an adult female. There is considerable resemblance between *Sts* 14 and the new specimen from Swartkrans, more so than between the latter and the *H. sapiens* equivalent, and in the light of this I consider that the Swartkrans specimen belongs to *Paranthropus*. There are, however, some noticeable differences between the two. Because a single specimen only of this vertebra is known from each of the sites, Sterkfontein and Swartkrans, it is unfortunately impossible to know what the significance is of the differences observed because the nature of the variation in the two parent populations is unknown.

SK 3981*a* is slightly larger than *Sts* 14. The maximum width of the superior face of the centrum in the former is 123 per cent of that of the latter, while the distance from the apex of the neural spine to the anterior surface of the centrum is 126 per cent of that in the Sterkfontein specimen. The maximum superior–inferior length of the centrum (nearest the neural canal) in *SK* 3981*a*, however, is only 105 per cent of that of *Sts* 14. The neural spine is proportionately longer in *SK* 3981*a*, being 107 per cent of the maximum antero-posterior diameter of the superior face of the centrum as compared with 89 per cent in *Sts* 14. The spine also differs in being orientated at right angles to the superior–inferior axis of the centrum, while those of modern man and of *Australopithecus* are swept downward at an appreciable angle. The neural canal is proportionately a little larger in the Swartkrans specimen: its width is 55 per cent of the maximum width of the superior face of the centrum and its antero-posterior height is 79 per cent, as compared with corresponding values of 50 per cent and 66 per cent in *Sts* 14.

The costal face on the base of the pedicle and the adjacent part of the centrum is very prominent in *SK* 3981*a*; it juts well away from the vertebra and faces quite strongly posteriad. That on the right side appears to be quite natural; that on the left side has the bone of the posterior portion of the facet thickened in an unusual way. In the *Australopithecus* specimen, the costal facets are well defined but are not nearly so protuberant as in *SK* 3981*a* and they face laterally. In both respects, *Sts* 14 resembles modern man considerably more than does *SK* 3981*a*. The transverse processes in *Sts* 14 are proportionately better developed than is the case in the Swartkrans specimen. In this respect also the Sterkfontein specimen resembles modern man more than does that from Swartkrans.

The superior and inferior faces of the centrum are rather more heart-shaped than are those of *Sts* 14, which are more rounded except for the concavity of the margin where it borders on the neural canal. In this feature the Swartkrans specimen is closer to modern man, but because there is some variability in this feature in modern man, larger samples of the fossil vertebrae might show much overlap.

From the larger size of the Swartkrans vertebra as a whole compared with the inferior–superior length of the centrum, and from the proportionately larger neural canal and spine, it seems fair to conclude that the individual from whom the Swartkrans vertebra came was appreciably more robust and muscular than the Sterkfontein individual, although the close similarity in length of the centrum in the two vertebrae suggests that the two had roughly similar statures. Put differently, one may say that the two vertebrae, both from adults, provide no evidence of difference in stature between the two individuals from whom they came but do provide evidence of difference in robustness. A single centrum (*Sts* 73) from Sterkfontein, which has the bases of the pedicles attached, is similar in superior–inferior length of the centrum to *SK* 3981*a*, but the cross-sectional area of the centrum is slightly greater in *Sts* 73. The individuals from whom these specimens came were therefore probably approximately similar with respect to both stature and robustness. From other evidence, such as femur size and robustness, it seems that the body of *Paranthropus* in South Africa was appreciably more robust than that of *Australopithecus*. If this was indeed so, then we may speculate that the *SK* 3981*a* specimen belonged to a female individual of *Paranthropus* and that there was overlap in body size between *Australopithecus* males and *Paranthropus* females.

Associated with *SK* 3981*a* was an incomplete last lumbar vertebra of an adult individual (*SK* 3981*b*). It consists of almost the entire centrum, the base of the right pedicle as well as much of the left pedicle and almost all of the transverse process. The specimen seems to belong to a higher primate and resembles most closely

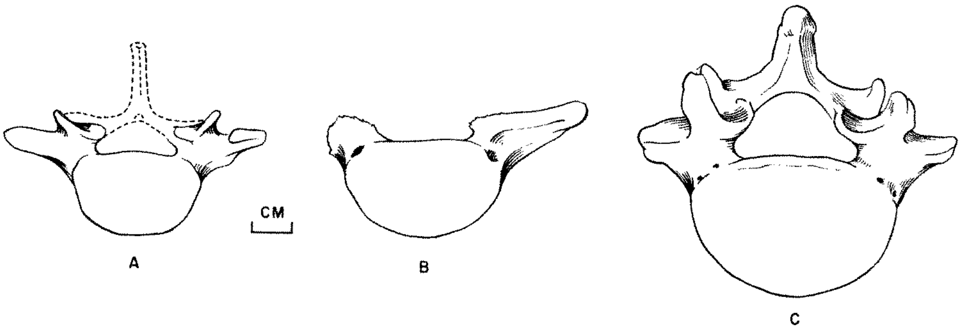

Fig. 2. Last lumbar vertebrae of (*A*), *Australopithecus* (*Sts* 14); (*B*), *Paranthropus* (*SK* 3981*b*); (*C*) *Homo sapiens* in superior view.

the one last lumbar vertebra of *Australopithecus* known (*Sts* 14).

The centrum is quite robust and the cross-sectional area of the superior face is appreciably greater than that of the inferior face. There is not much detail to be had from the specimen because all of the articular facets are gone as well as most of the neural arch and spine. The transverse process on the left side is very large compared with that of *Australopithecus* and is considerably larger even than that of modern man. As in the case of the latter two, the transverse process projects superiorly as well as laterally. In the Swartkrans specimen there is a tubercle on the inferior aspect of the transverse process which covers quite a large area (14·5 × 8·5 mm) but is not prominent. In the *Sts* 14 specimen of *Australopithecus*, this process is quite different and is very prominent, forming a very substantial part of the transverse process mass. In neither is the process like the usual condition in modern man, but that in *SK* 3981*b* is a little more like it than is that of *Sts* 14.

The neural canal in *SK* 3981*b* was wide (21·4 mm) but low, judging from what remains of it. The body not only has an appreciable disparity between the areas of the inferior and superior surfaces, but also is deeper anteriorly than it is posteriorly, that is, next to the neural canal (19·0 and 21·3 mm). This latter feature suggests a well developed promontory and lumbar lordosis. The former indicates that, as in *Australopithecus*, the body of the first sacral vertebral element was relatively small. The relatively great disparity between the inferior and superior surface areas of the body of the last lumbar vertebra seen in both the Sterkfontein and Swartkrans specimens is not typical of modern man, though there is a disparity of much smaller magnitude.

As in the case of *SK* 3981*a*, *SK* 3981*b* has a superior–inferior centrum length which is only slightly greater than that of *Sts* 14. But the cross-sectional area of the centrum is appreciably greater in the Swartkrans specimen, being 128 per cent as wide as that of *Sts* 14 in the case of the superior surface.

I conclude that both of the Swartkrans vertebrae belong to *Paranthropus*, and it also is likely that they came from a single individual. This conclusion is based on the rarity of hominid vertebral remains in the South African sites, hence two found directly associated are probably related, as well as the fact that the size relationship between the two closely matches that between the appropriate vertebrae in the Sterkfontein vertebral column *Sts* 14. Whether or not they came from a single individual, the Swartkrans specimens resemble the two known *Australopithecus* equivalents more closely than they do those of modern man. This material as a whole thus indicates that early hominids had vertebrae which are not only easily distinguishable from those of pongids but also are distinguishable from those of modern man. Furthermore, the material indicates that some differences existed between the *Australopithecus* and *Paranthropus* vertebrae. Because of the scantiness of this material, however, it is impossible to know whether adequate samples would reveal these as taxonomic differences or merely as individual variation. Because other, non-vertebral, evidence suggests appreciable differences between the two taxa, some differences could be expected also in the vertebrae. These vertebrae, for example, provide evidence of a difference in robustness —this is supported by other evidence. The evidence of these two vertebrae also makes it more likely now that, in spite of the difference in robustness, the population ranges for stature in the two taxa probably overlapped extensively. The robustness may have overlapped in such a way that *Paranthropus* females and *Australopithecus* males were similar in robustness as well as stature; but much more evidence is needed to prove or disprove this conclusion.

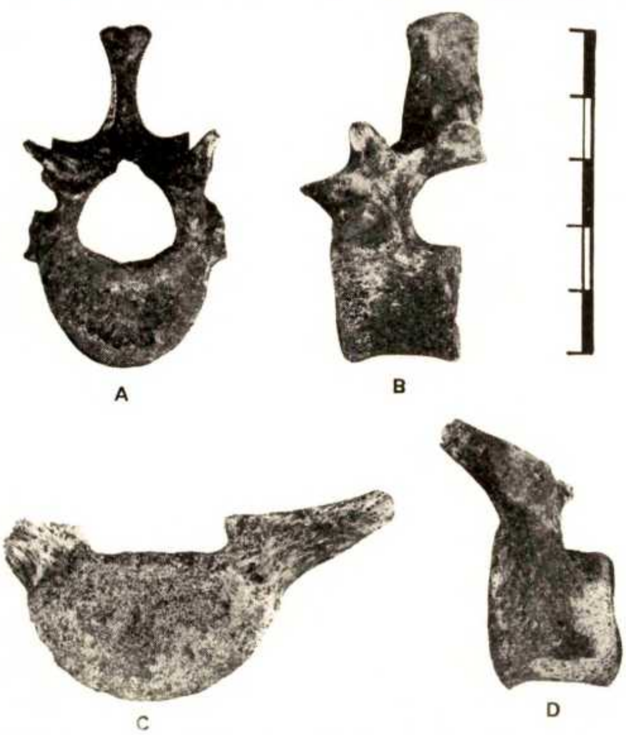

Fig. 3. *Paranthropus* vertebrae from Swartkrans. Last thoracic (*SK* 3981*a*), superior view (*A*), left lateral view (*B*); last lumbar (*SK* 3981*b*), superior view (*C*), left lateral view (*D*).

I thank Dr C. K. Brain of the Transvaal Museum, Pretoria, for allowing me to examine the Swartkrans material. This work was supported by the US National Science Foundation.

More Evidence of an Advanced Hominid at Swartkrans

In July 1969, while two of us (R. J. C. and F. C. H.) were examining the australopithecine collections in the Transvaal Museum (Pretoria), one of us (R. J. C.) noticed that parts of a cranium (*SK* 847) from Swartkrans appeared to differ substantially from the robust australopithecine (*Paranthropus*) known in abundance from that site. Although the specimen had previously been regarded as *Paranthropus*, the possibility immediately came to mind that it might provide further evidence of the second hominid reported from that site by Broom and Robinson[1-3] in 1949 and then referred to *Telanthropus capensis*, but subsequently assigned by Robinson[4] to *Homo erectus*. Remains considered to represent this second hominid include a nearly complete mandible with most of the molar teeth (*SK* 15), an isolated worn left P_3 (*SK* 18*a*) thought to be from the same individual, a mandible fragment with two worn molar teeth (*SK* 45) and a maxilla fragment with worn and incomplete I^2, P^3 and P^4 (*SK* 80). A proximal radius (*SK* 18*b*), found closely associated with the type mandible (*SK* 15), has also been referred to the same hominid by Robinson[5].

After assembling portions of the *SK* 847 specimen, along with much of a left temporal (*SK* 846*b*), it was noted that there was a perfect join across the left side between the posterior palatal fragment of *SK* 847 and the previously known maxillary fragment *SK* 80. This perfect fit is clearly visible in Fig. 1.

The specimen now comprises most of the left side of the face, the left infratemporal fossa, and the left temporal region all in contact. The face includes the complete left

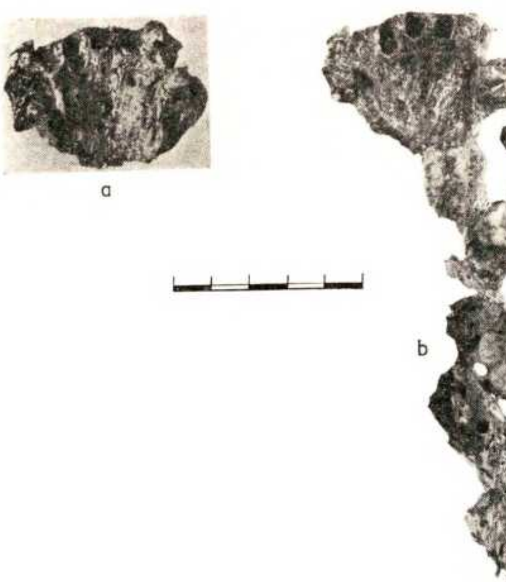

Fig. 1. (*a*) Palatal view of maxillary fragment (*SK* 80) as figured by Robinson[5]; (*b*) basal view of the assembled cranium (*SK* 847 and 846*b*) and the joined maxilla fragment, *SK* 80.

orbit and supraorbital torus and a bit of the adjacent frontal squama; the zygoma and anterior portion of the zygomatic arch; the complete nasal bones; the upper portion of the maxilla including the frontal process, orbital surface and the zygomatic process, as well as the posterior part of the palatal process with worn left M^3 in place and the distobuccal root of M^2; the anterior portion of the palate (*SK* 80) which is intact between the canine sockets, with worn left I^2, and bits of the roots of left and right P^3 (also an isolated lingual root of the right P^3 and a piece of the root and crown of the right P^4). The infratemporal region includes the left lateral pterygoid plate, a part of the greater wing of the sphenoid with infratemporal crest and foramen ovale. A substantial portion of the left temporal is present and comprises some of the squamous, tympanic and petro-mastoid elements, including the antero-inferior portion of the squamous part, the root of the zygomatic process, the preglenoid region, the mandibular fossa, the external auditory meatus, the inferior portion of the mastoid process (with exposure of the mastoid air cells) and the petrous temporal. A small fragment of the inferolateral border of the occipital is attached at the occipitomastoid suture. It should be noted that these skull parts are all attached and there is no crushing or distortion—the specimen having been prepared from its enclosing breccia by the acetic acid method—other than a slight lateral warping of the palate in relation to the midline of the face.

Other loose fragments from the same block of breccia and assumed to belong to the same individual include a small fragment of occipital with the left condyle, anterior condylar canal and jugular notch (847*j*), and a substantial fragment of the left orbital plate of the frontal adjoined to a fragment of the left lesser wing of the sphenoid with the optic foramen (847*d*). Also from this block of breccia are several other fragments which may or may not belong to the same skull. These are four thin intracranial fragments (847*k*, *l*, *m*, *n*), a large portion of thick left parietal, with sagittal and lambdoid sutures, and a well-delineated temporal line (847*e*), as well as two fragments of cranial vault (847*h* and *i*). Two other fragments labelled *SK* 847*f* and *g* do not belong to this specimen.

In his appraisal of the maxillary fragment *SK* 80, Robinson[5] stated that it differed from the Swartkrans robust australopithecine in the relatively great depth of the palate anteriorly, the shallow canine socket and the size and conformation of the incisive fossa and its immediate surroundings. He also noted that, in lateral view, the midline of this maxillary specimen is visible, whereas in the robust australopithecine this is not the case, because the canine roots and eminences are very robust, while the intercanine region of the maxilla is depressed. He also directed attention to the posterior situation in the nasal aperture of the anterior nasal spine and the lack of a well-differentiated sill or inferior margin of the nasal aperture in this australopithecine. By contrast, in the *SK* 80 specimen, the nasal spine is situated toward the front of the nasal aperture and there is a sharply defined sill-like inferior margin. He further mentioned that the vomer in the robust australopithecine is continuous with the back of the nasal spine, whereas in *SK* 80 there is a separation of 1 centimetre between the anterior nasal spine and the anterior point of the vomer.

The addition of a substantial portion of the upper facial skeleton and the lateral part of the cranial base to the maxillary fragment of *SK* 80 enables us to confirm that Robinson was quite correct in assigning this specimen to a hominid other than the robust australopithecine of Swartkrans. Moreover, it is now possible to demonstrate that the second hominid differed in several important features, not only from the robust, but also from the gracile form of australopithecine. In the following discussion, this new specimen (*SK* 847, *SK* 846*b*), together with the maxillary fragment (*SK* 80), will be treated as a unit and designated as *SK* 847.

In *SK* 847 the supraorbital torus is pronounced, being thickened both in its supraciliary (medial) and supraorbital (lateral) portions, the latter being rather markedly curved latero-inferiorly (Fig. 2). The specimen is broken in the midline, but the supraglabellar portion was evidently only slightly depressed between the adjacent supraciliary portions of the torus. This break exposes a substantial frontal sinus, extending laterally about 19 mm, distally about 22 mm, and superiorly about 16·5 mm. The postorbital constriction was only moderately developed at most. By contrast, in the robust australopithecine from Swartkrans, the supraorbital torus is thin, flattened and slopes smoothly backward into the frontal squama. The supraglabellar area is an extensive flattened planum with its postero-lateral margins defined by the postero-medially directed anterior temporal lines, which pass into a mid-sagittal crest in adult individuals. Postorbital constriction is markedly developed in robust australopithecines, both in South Africa and East Africa (*A. boisei*). In *Australopithecus africanus* (from Sterkfontein) the supraorbital torus is also thin and flattened, sloping posteriorly and gently superiorly into the frontal squama

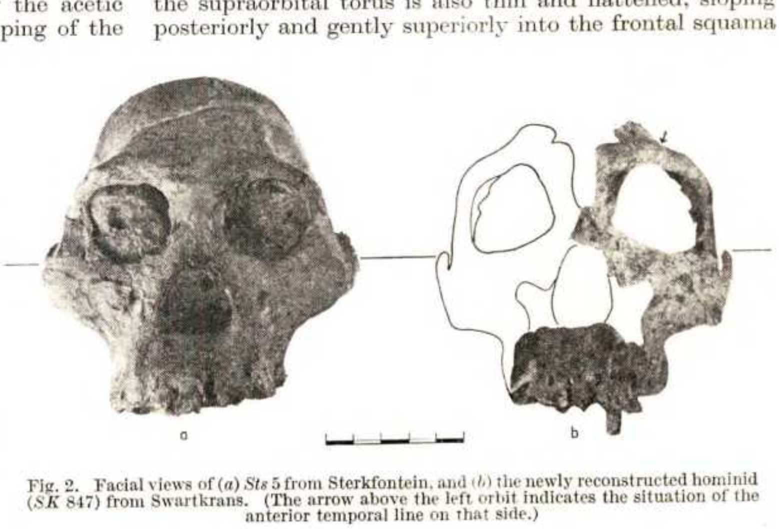

Fig. 2. Facial views of (*a*) *Sts* 5 from Sterkfontein, and (*b*) the newly reconstructed hominid (*SK* 847) from Swartkrans. (The arrow above the left orbit indicates the situation of the anterior temporal line on that side.)

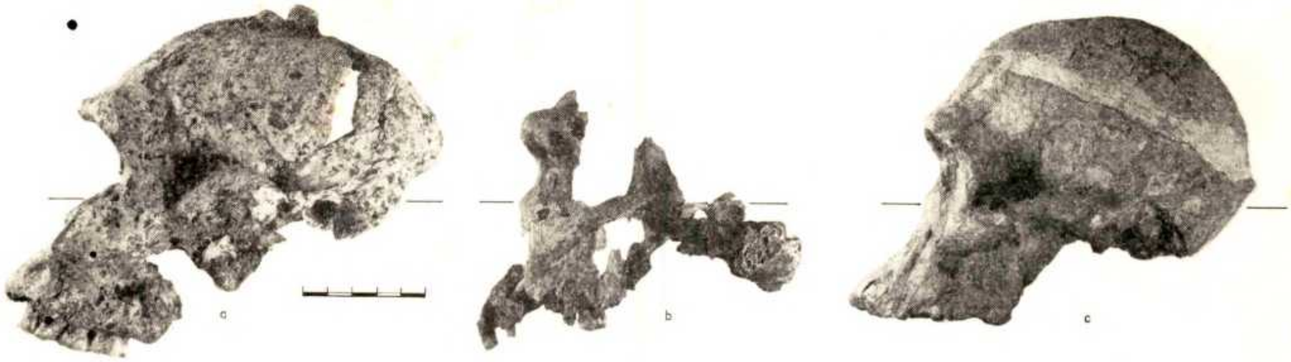

Fig. 3. Lateral views of (*a*) a robust australopithecine (*SK* 46) from Swartkrans; (*b*) the newly reconstructed specimen (*SK* 847)—a second hominid from Swartkrans; and (*c*) a gracile australopithecine (*Sts* 5) from Sterkfontein.

(Fig. 3). The supraglabellar planum is substantially less well developed and defined than in the robust australopithecines from Swartkrans. The degree of postorbital constriction is generally reduced in the gracile australopithecine from Sterkfontein, although it may be fairly substantial as in the *Sts* 17 individual; in any case, it differs from the characteristic robust australopithecine condition.

In *SK* 847, the frontal squama is undistorted and it slopes sharply upward behind the supraorbital torus. There is consequently a broad supratoral sulcus. The lower part of the frontal squama is obliquely fractured to expose the cancellous bone and its substantial thickness. In both the gracile australopithecine from Sterkfontein and the robust form from Swartkrans (Fig. 2), the suprafacial torus passes gently posteriorly into the squama, without well defined angulation between the squama and the torus. There is a complete absence in *SK* 847 of the very sharply defined posterior margin of the zygomatic process of the frontal, that is to say, the supraorbital element of the torus, which is so characteristic of the robust australopithecine from Swartkrans (for example, the individuals represented by *SK* 52, *SK* 48, *SK* 46 and *SK* 79). The frontal sector of the anterior temporal line is indicated in *SK* 847, but it is ill defined and not salient, and it is situated far laterally by comparison with its origin along the entire posterior margin of the supraorbital sector of the suprafacial torus in the robust australopithecines. This condition is less extreme in the gracile australopithecine from Sterkfontein (for example, *Sts* 5, *Sts* 71), but both the robust and gracile australopithecine condition contrasts markedly with that in the *SK* 847 individual.

In regard to the *SK* 80 maxillary fragment, Robinson[5] observed that from "the conformation of the immediate neighbourhood of the lower portion of the nasal aperture it seems probable that the bone surface on either side of the anterior nasal aperture was directed more nearly vertically than is the subnasal plane. The appearance of this general region must have been very similar to that in *Pithecanthropus* IV [Sangiran maxilla]. If this is the case there must have been a more definite projection of the [bony] nose in *Telanthropus* than is the case in *P. crassidens*". The new specimen (*SK* 847) now confirms Robinson's inference. The nasal bones are prominent, projecting well forward such that, in lateral view, they approach the plane linking the supraorbital torus with the anterior teeth. By contrast, in both robust and gracile australopithecines, the nasal bones are flattened, in approximately the same plane as the adjacent frontal process of the maxilla (the respective planes are different in the *SK* 847 specimen) and are situated behind or on a level with the plane of the zygoma.

The dental arcade of *SK* 847 is quite short (60 mm). The mandibular fossa is situated closer to the occlusal plane than in either robust or gracile australopithecines. This clearly indicates that the skull must have had a small mandible with a low ascending ramus. In describing the type mandible (*SK* 15) of the non-australopithecine hominid from Swartkrans, Robinson[5] noted that, although both mandibular condyles were missing, the break in the ascending ramus on the right side of the specimen occurred at that point where the ramus was thickening just below the condyle; on the left side, the break occurred in the same relative position. He therefore concluded that the ascending ramus was low and in his reconstruction of the specimen he gave it a condylar height of 55 mm. If the mandible of *SK* 15 is occluded with the skull of *SK* 847, the broken portion of the left ramus reaches about 18 mm below the articular eminence of the mandibular fossa. In this position the dental arcades match well (Fig. 4*c*). If allowance is made for breakage, and for some extension

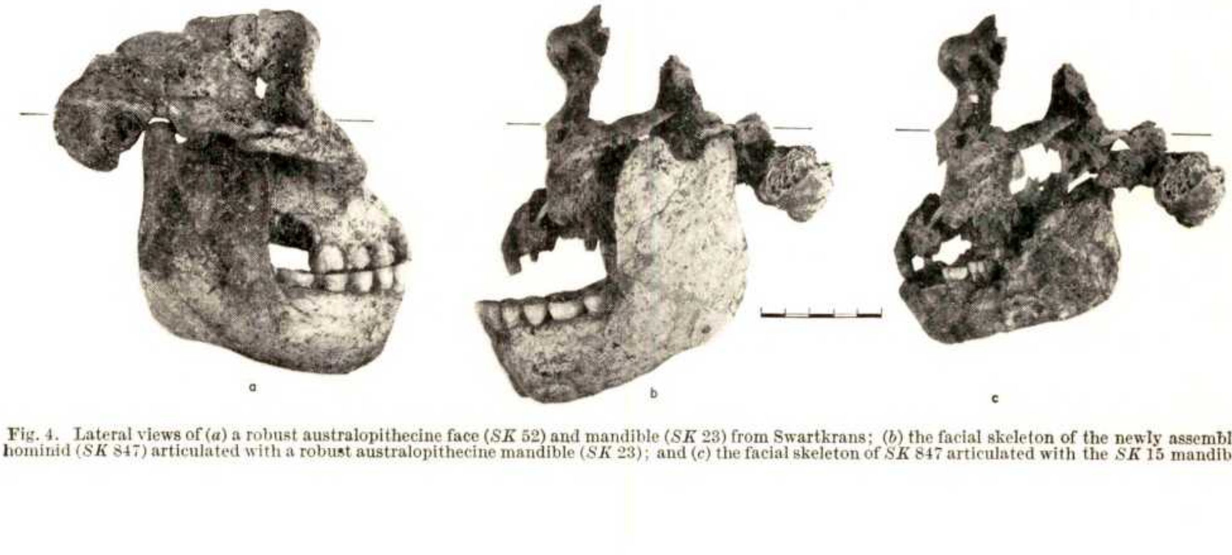

Fig. 4. Lateral views of (*a*) a robust australopithecine face (*SK* 52) and mandible (*SK* 23) from Swartkrans; (*b*) the facial skeleton of the newly assembled hominid (*SK* 847) articulated with a robust australopithecine mandible (*SK* 23); and (*c*) the facial skeleton of *SK* 847 articulated with the *SK* 15 mandible.

of the type mandible (*SK* 15) caused by crushing, then the measurement of the dental arcade would be very comparable with that of *SK* 847. The dental arcade of the type mandible in its distorted state is about 66 mm, but, when undistorted, would have approximated 60 mm. If, however, the condyle of a fairly "gracile" Swartkrans australopithecine mandible (*SK* 23) is fitted to the mandibular fossa of the newly assembled *SK* 847 specimen, the upper and lower teeth could not occlude, and the mandible projects far forward of the maxilla (Fig. 4*b*). On the other hand, the same mandible (*SK* 23) articulated nearly perfectly with the incomplete robust australopithecine basicranial fragment of *SK* 52 (Fig. 4*a*). It is clear that only a mandible of the size of *SK* 15, with a low ascending ramus, could have fitted this newly assembled skull of *SK* 847. The heavy wear on the M^3 of *SK* 847 shows that it could not, in fact, belong with the comparatively little worn mandible of *SK* 15, but the advanced hominid right mandible fragment, *SK* 45, with heavily worn M_1 and substantially worn M_2 could possibly represent the same individual as *SK* 847.

The buccolingual width of the left M^3 of *SK* 847 is 15·4 mm. There is a large mesial interproximal wear facet, so it is not possible to determine accurately its mesiodistal length. The actual minimum length measurement across this facet is 11·7 mm; its original length could have been as much as 12·7 mm.

The parietal fragment (*SK* 847*e*) is not complete. The length measurement on a chord, from the broken anterior edge along the sagittal suture to lambda, is 82·5 mm. The maximum thickness, taken on the sagittal suture 22 mm anterior to lambda, is 7·5 mm, but the maximum thickness on the posterior part of the temporal line is 8·5 mm. The distance of the temporal line below the sagittal suture is 37 mm (at lambda) and 39 mm at a maximum further forward. This indicates a pattern of temporal musculature origin which differs very markedly from that known to be characteristic of robust australopithecines.

The recognition of this specimen from Swartkrans removes it from the inventory of robust australopithecine individuals from this site[6]. The specimen confirms Robinson's view of the presence at that site of two distinct hominids. The most abundant, represented by at least sixty individuals, is a robust australopithecine variously designated as *Paranthropus robustus* or *Australopithecus robustus*. The second hominid, represented thus far by six catalogued specimens, clearly differs from that robust australopithecine and also from gracile australopithecines, as Robinson has long maintained. Its lower dentition and the structure of its facial skeleton and mandible indicate to us that it should be regarded as a species of the genus *Homo*. There are some resemblances to *Homo erectus*. It is preferable, however, until further fossil material is recovered as a consequence of renewed work at Swartkrans[7], to treat the remains as *Homo* sp. indet.

This work was made possible by a study grant to one of us (R. J. C.) from the Wenner-Gren Foundation for Anthropological Research and to the second author (F. C. H.) by a grant, in conjunction with the work of the Omo Research Expedition, from the US National Science Foundation.

Stone Artefacts from Swartkrans

WHILE in South Africa on a visit to study the cultural material from the australopithecine sites, I was invited by Dr C. K. Brain to describe the artefacts he had obtained from Swartkrans[1]. Examination of this series and of the tools excavated from the Sterkfontein Extension Site has proved to be of particular interest on account of certain resemblances to developed Oldowan assemblages from Bed II, Olduvai Gorge, now being analysed for publication in volume three of the Olduvai series.

I have only taken into account specimens that are unquestionably derived from the pink breccia. The assemblage studied consists of twenty-seven artefacts, most of which still have patches of matrix adhering to them or else are specimens that have been removed from the breccia under Dr Brain's personal supervision. On the basis of the terminology used in describing the cultural material from Olduvai Gorge, the following tools, flakes and utilized material can be distinguished (Table 1).

Table 1

Side choppers	8	Heavy duty pick	1
End choppers	2	Heavy duty scrapers	2
Pointed chopper	1	Light duty scraper	1
Bifaces	3*		
Cleaver	1	Anvils	2
Discoid	1	Flakes	4
Sub-spheroids	2	Utilized cobbles	2
			30

* These bifaces were found after this paper had been written. It should be noted that they are proportionately less common than would appear, because other artefacts have also been found, which it has not been possible to describe here.

Quartzite, generally in the form of cobbles, is the most common raw material (twenty-one specimens), but one side chopper and the cleaver are made from diabase, the discoid from chert and another side chopper from vein quartz. With the exception of three diabase specimens and one massive quartzite side chopper, which are weathered, all are in sharp condition.

Tools

Side choppers. Three of the eight side choppers are unifacial (*SK* 3947, *SK* 3948 and *SK* 3964). Two are made from quartzite cobbles with a smooth cortex surface forming the butt ends and one from diabase. In one example, the working edge has been flaked only from the cortex surface and in two from a single negative flake scar (Fig. 1*b*, *SK* 3948). The working edges are usually more even than in the bifacial choppers, although secondary trimming scars are only visible on the figured specimen. In one example there is battering and damage on the butt end, indicating additional use as a hammerstone. In the diabase specimen, the butt is formed by a flat vertical face similar to that in the vein quartz chopper described below. (Measurements: 80 × 86 × 50 mm; 85 × 92 × 66 mm; and 69 × 76 × 43 mm. Working edge circumference ratios, 22 per cent, 29 per cent and 36 per cent.) The five bifacial side choppers are *SK* 3973, *SK* 3965, *SK* 3951, *SK* 3967 and *SK* 3971. *SK* 3973 is made from vein quartz (Fig. 1*d*). The working edge is jagged, chipped and partly blunted by use and the butt is formed by a flat vertical surface. The nature of the material makes accurate determination of flake scars difficult, but this specimen appears to have been flaked over the upper and

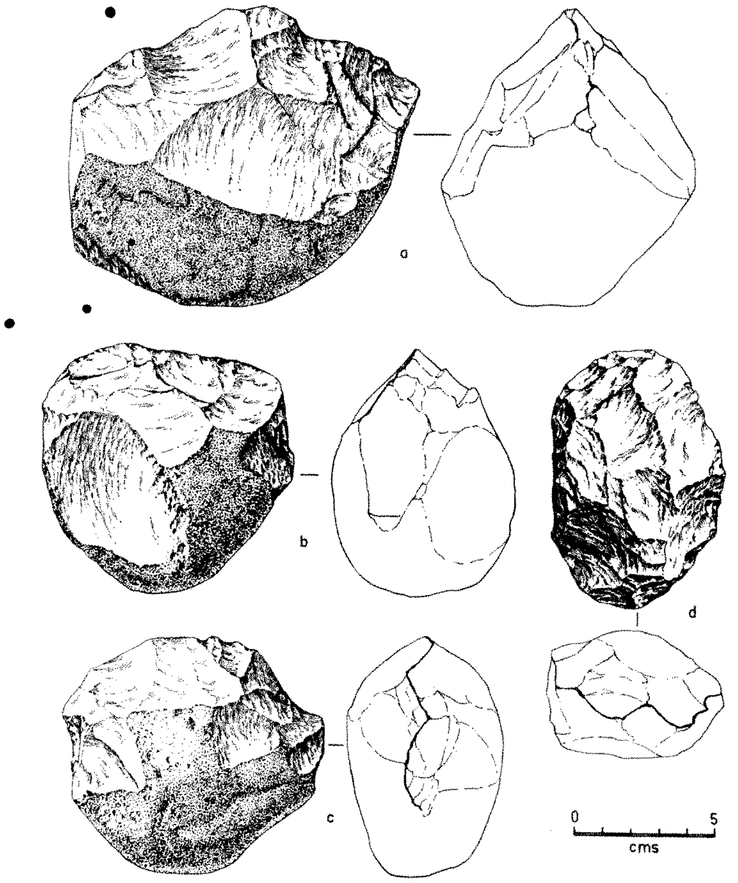

Fig. 1. Stone artefacts from Swartkrans: side choppers, *a*, *SK* 3951; *b*, *SK* 3948; *c*, *SK* 3967; and *d*, *SK* 3973.

lower faces, as well as along the working edge and butt. (Measurements: 50 × 92 × 41 mm, working edge/circumference ratio 36 per cent.) *SK* 3965 and *SK* 3951 are two massive specimens, both made from quartzite and weighing 3 pounds 2 ounces and 3 pounds 0 ounces respectively. The butts are formed by natural weathered surface or rounded cortex. The working edges are jagged and sharp but chipped by use and in one example also partially blunted. In the second specimen (Fig. 1*a*) projecting areas on the butt have also been battered and damaged. (Measurements: 108 × 117 × 88 mm and 106 × 131 × 88 mm, working edge/circumference ratios 55 per cent and 36 per cent respectively.) *SK* 3967 (Fig. 1*c*) is a particularly well made example of a "classic" chopper, made from a quartzite cobble, with multiple bifacial flaking of the working edge and a rounded butt formed by cortex surface. It is in mint condition with only a minimum of chipping on the working edge, including a crushed notch 15 mm wide. (Measurements: 85 × 96 × 57 mm, working edge/circumference ratio 56 per cent.) *SK* 3971 is a small, oblong specimen, made from a quartzite cobble. One edge is almost vertically flaked and the intersection of this surface with the upper and lower faces forms two working edges along the same side, both of which show some bifacial flaking. The butt is formed by a rounded cortex surface. (Measurements: 52 × 72 × 37 mm.)

End choppers (*SK* 3950 and *SK* 3949). Both examples are made from quartzite cobbles and both are unifacial. In one the working edge is trimmed from a single negative scar and the other, which exhibits only a minimum of flaking, has been trimmed from the cortex surface. The specimen is made on an oblong cobblestone flaked transversely across one end. In the second example, the working edge is at the wide end of the cobble, which tapers towards the butt end. Both specimens are in sharp condition, although the working edges have been considerably chipped by use. (Measurements: 108 × 60 mm and 123 × 74 × 55 mm. Working edge/circumference ratios 26 per cent and 27 per cent.)

Pointed chopper (*SK* 3966). Made from a quartzite cobblestone with a small area of cortex surface retained at the butt and on one face. This specimen is diamond-shaped in cross-section, towards the tip, with a marked longitudinal ridge on both the upper and lower faces, formed by the intersection of the trimming scars on either edge. The tip is bluntly pointed and the edges on either side are chipped by use. In mint condition. (Measurements: 71 × 65 × 56 mm.)

Bifaces. Two of the three bifaces are considerably weathered. In *SK* 3979, made of quartzite, the ridges intervening between the flake scars are abraded and rounded, so that the specimen appears to be rolled (Fig. 2*c*). In *SK* 3980, made of diabase, the edges are relatively sharp, but the whole surface is pitted and damaged by weathering (Fig. 2*b*). *SK* 7879, made of dolerite, is in mint condition (Fig. 2*a*). *SK* 3979 (98 × 58 × 38 mm) is asymmetrical, with an oblique butt which is relatively thick in relation to the pointed end. A longitudinal dorsal heel is present on one face (opposite to that illustrated) and the flaking is simple, with large, deeply indented scars. The edge is sinuous and there is some irregular chipping which may have been caused by use. *SK* 3980 (122 × 87 × 49 mm) might be described as a crude ovate. It is difficult to determine the nature of The trimming scars on account of the extensive weathering, but they appear to be flatter and more accurately directed than in the previous specimen. The edge is relatively straight and the cross-section is biconvex and symmetrical. *SK* 7879 (137 × 95 × 32 mm) is made on a side-struck flake in which the bulb has been trimmed away. The edges are almost straight and the tip is sharply pointed. The butt is also pointed, but is formed by the intersection of an oblique natural fracture with a flake scar on the primary surface. Trimming of the edge is confined to the dorsal aspect and extends round the circumference with the exception of an area near the butt.

Cleaver (*SK* 3962). This is made on a relatively thin side-struck flake, approximately quadrilateral in shape (Fig. 2*d*). Both lateral edges are trimmed by means of shallow well-controlled flaking and the bulb has also been trimmed off. The tool is square-ended and the edges at both extremities are thin and sharp and are formed in typical cleaver fashion by the intersection of broad flat scars with the primary flake surface. Slight chipping is evident at the broader end. This specimen is extensively weathered, but would fit comfortably within a middle or upper Acheulean assemblage. (Measurements: 124 × 86 × 25 mm.)

Heavy duty pick (*SK* 3955). A crude, asymmetrical specimen, made from a cobble of coarse-grained quartzite (Fig. 3*a*). Cortex is present on one face and on the butt end. The tip is bluntly pointed and quadrilateral in cross-section, with marked longitudinal ridges on the upper and lower faces, at the intersection of the trimming scars from either edge. One lateral edge is also bifacially flaked for the greater part of its length. At the butt end, the surface has been battered and pitted along a projecting ridge. (Measurements: 150 × 95 × 68 mm.)

Discoid (*SK* 3959). A flat, relatively thin specimen made from chert (Fig. 3*c*). The circumference is uneven and the whole tool is somewhat irregular in shape. Radial trimming is evident on one face, but the obverse appears to consist largely of a natural fracture surface. Chipped utilization is present along part of the edge. (Measurements: 70 × 69 × 26 mm.)

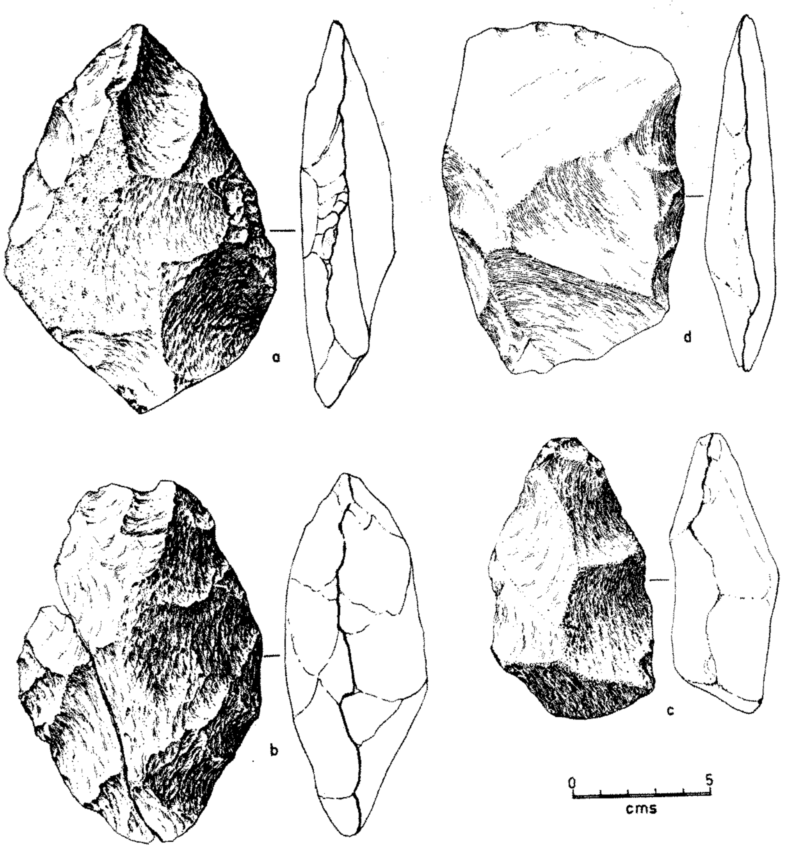

Fig. 2. Stone artefacts from Swartkrans: bifaces (*a*) *SK* 7879; (*b*) *SK* 3980; (*c*) *SK* 3979; and cleaver (*d*) *SK* 3962.

Sub-spheroids (*SK* 3956 and *SK* 3957). Both these specimens are of quartzite and both are faceted although the greater part of the surfaces have been battered, so that projecting ridges are blunted and partly obliterated. One example is oblong, but shows identical flaking and wear to that on the more spherical specimens. (Measurements: 85 × 72 × 68 mm and 88 × 66 × 58 mm.)

Heavy duty scrapers (*SK* 3963 and *SK* 3960). One example is made on a quartzite flake 84 mm long and 88 mm wide, struck from a cobblestone. Approximately 50 per cent of the circumference has been steeply but irregularly trimmed. The edge is chipped and blunted by use on the dorsal aspect and there is also a crushed notch 12 mm wide and approximately 4 mm deep. The second specimen is made on a sub-spherical quartzite cobble with cortex remaining on the greater part of the exterior (Fig. 3*b*). The working edge has been steeply and evenly trimmed from a single negative scar on the under-surface and the edge is considerably blunted by use. In many respects this specimen resembles the unifacial chopper *SK* 3948 except for the angle of the working edge, which is approximately a right angle instead of being acute. (Measurements: 96 × 80 × 60 mm.)

Light duty scraper (*SK* 3970). A small "nosed" scraper made on a fragment of quartzite 34 mm long and 24 mm wide. The working edge is steeply trimmed with a notch on either side of a small, rounded scraper edge.

Anvils (*SK* 3958 and *SK* 3952). Neither of these specimens can be considered as typical, but they have been classed as anvils because they more closely resemble these tools than any other category. *SK* 3958 consists of a large oblong quartzite cobble with a longitudinal flake removed from one face. Further flakes have been struck from both lateral edges of this flake scar, forming approximately right-angled edges which have been battered and step-flaked in the manner seen on more typical anvils. The edges of some subsidiary scars on one side of the main flake scar also show similar utilization. (Measurements: 160 × 87 × 85 mm.) The second example is a sub-spherical quartzite cobble, flaked on one face to a blunt edge. In some respects it resembles a chopper, except for the angle of the edge, which exceeds 90°. Blunting and battering are evident on the edge. (Measurements: 77 × 52 × 60 mm.)

Flakes. These consist of three whole and one broken quartzite flakes. The complete flakes are end-struck, and one has been slightly chipped along the edges. The largest specimen is a cortical flake struck from a cobblestone. (Measurements: 73 × 70 mm, 70 × 36 mm and 38 × 27 mm respectively.)

To sum up the characteristics of the industry which I have described, choppers can be said to constitute 37 per cent of the tools, while other forms are scantily represented. Polyhedrons do not occur at all. The outstanding tool is the diabase cleaver which seems to be too evolved to be compatible with the remainder of the series. The nature of the material, which permitted well controlled flaking, may, however, be the cause of this. (The existence of a cleaver in such a context would scarcely have been accepted until recent years, when several specimens have come to light at Olduvai Gorge in similar assemblages.)

Comparisons with Sterkfontein Artefacts

In order that these notes on the collection of artefacts from Swartkrans may be more meaningful, it is useful to compare them briefly with the much larger assemblage recovered by Dr J. T. Robinson from the pink breccia at the Sterkfontein Extension Site which probably does not antedate the Swartkrans material by any significant interval of time*.

As a result of examining the Sterkfontein material in the light of familiarity with developed Oldowan assemblages from East Africa, I do not agree with Mason's classification published in 1962 (ref. 2). None of the material from Olduvai was then available for study, and Dr Mason himself would now probably find reason for modifying his classification if he had the opportunity to examine it. He lists a large number of cores, only two choppers, one whole and one broken biface. He also states that polyhedrons are not present. In my view, there are only two or three specimens which can be classed as cores and I would term the greater part of Dr Mason's "cores" as either choppers or polyhedrons. I also consider that there are not two but three complete and five broken bifaces. Leaving aside the utilized material, manuports and debitage (of which there is singularly little), I would prefer to re-classify the tools as shown in Table 2.

Table 2

Side choppers	19
End choppers	4
Bifaces (3 complete, 5 broken)	8
Polyhedrons	23
Discoids	4
Spheroid	1
Sub-spheroids	3
Scrapers, heavy duty	10
Scraper, light duty	1

The principal difference between my classification and that published by Dr Mason lies in my rejection of his "cores" and the allocation of these specimens either to polyhedrons (the term polyhedron has been defined elsewhere as referring to specimens with three or more cutting edges) or choppers. This is because I am reluctant to class artefacts as cores unless there is evidence to indicate that they were by-products of tool-making and jettisoned as debitage when the required flakes had been obtained from them. This is not the case at Sterkfontein, where flake tools are almost absent. Added to this, cores in the strict sense should show little or no utilization whereas the Sterkfontein specimens are often considerably chipped by use and blunted on the edges, as indeed was noted by Dr Mason. I consider therefore that they should rank rather as end-products or tools, in common with choppers, discoids or spheroids, which are, in fact, also "cores" in the sense that they are nuclei from which flakes have been detached.

---

* The material from the pink breccia at Makapansgat was kindly put at my disposal by Professor R. Dart and Mr B. Maguire, but, although it included a number of quartzite flakes and utilized pieces, there do not seem to be recognizable tool forms among the *in situ* specimens.

In connexion with the lack of flakes, it may be noted that at sites in Olduvai Gorge when similar assemblages occur, including choppers and polyhedrons and where the heavy duty tools are usually made from lava, there are likewise insufficient flakes for the number of tools present, had they been made on the spot, although quartz and quartzite flakes are often abundant. It would therefore seem that heavy duty tools were usually made away from the living sites, wherever the raw materials were obtained. Sterkfontein should almost certainly be considered as a domestic site in view of the localized concentration of artefacts in the area of the West Pit and Sterkfontein Extension Site and their virtual absence nearby at the same horizon. The position at Swartkrans is still not clear and the conditions under which the artefacts occur will only be known when the detailed excavations planned by Dr Brain have been carried out.

Comparisons with Olduvai Artefacts

One of the most striking features in the assemblages from Swartkrans and Sterkfontein is the relatively large size of the tools when compared with similar specimens from Olduvai, although a high proportion at both sites are made from cobbles. This is clearly demonstrated by the figures for the average mean diameters of side choppers, a tool class which is numerically strong at all three sites (Table 3).

Table 3

Swart-krans	Sterkfon-tein	Olduvai Lower Bed I (*DKI*)	Olduvai Upper Bed I (*FLK* N)	Olduvai Middle Bed II (*MNK*)	Olduvai Upper Bed II (*TK*)
79 mm	71 mm	65 mm	65 mm	64 mm	61 mm

The collection from Swartkrans is unfortunately too limited for quantitative analysis, but a comparison of the Sterkfontein assemblage with assemblages from developed Oldowan sites in Bed II, Olduvai, is shown in Table 4.

Table 4

	Sterk-fontein	*MNK* II (Mid Bed II)	*SHK* II (Upper Bed II)	*TK* II (Top Bed II)	*BK* II (Top Bed II)
Choppers	37·0%	17·5%	17·5%	9·9%	15·8%
Bifaces	10·0	2·0	7·0	8·6	5·1
Polyhedrons	29·0	—	2·3	1·0	1·3
Discoids	5·0	5·3	6·3	3·1	3·9
Spheroids and sub-spheroids	5·1	36·3	34·6	26·5	27·9
Scrapers, heavy duty	12·6	5·1	5·2	4·5	2·5
Scrapers, light duty	1·3	10·8	8·0	26·5	14·1
Other heavy duty tools	—	19·7	14·0	10·6	12·1
Other light duty tools	—	3·3	5·0	9·2	17·2

It will be seen that choppers and polyhedrons are proportionately far more numerous at Sterkfontein, with 37 per cent and 29·0 per cent respectively as against 17·5 per cent and 2·3 per cent, which are the highest figures for these tools at Olduvai. Bifaces are also slightly more numerous, although the difference between the highest Olduvai figure of 8·6 per cent at *TK* and 10·1 per cent at Sterkfontein is probably not of great significance. Spheroids and sub-spheroids are very much scarcer at Sterkfontein than at any of the Olduvai sites, where they are always plentiful in developed Oldowan assemblages. At Sterkfontein, too, heavy duty scrapers outnumber light duty specimens, whereas at Olduvai the latter are nearly always more plentiful.

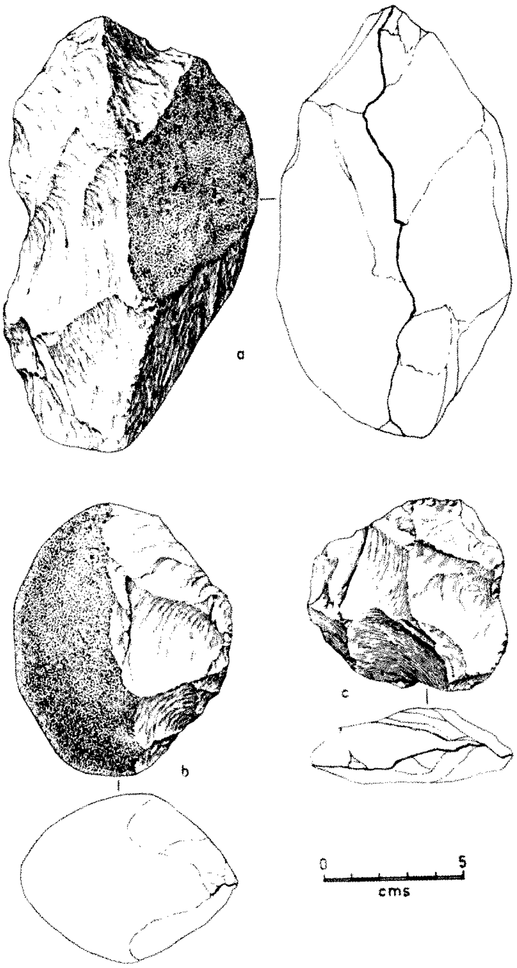

Fig. 3. Stone artefacts from Swartkrans: (*a*) heavy duty pick *SK* 3955; (*b*) heavy duty scraper *SK* 3960; (*c*) discoid *SK* 3959.

In spite of the difference in the relative proportions of the various tool forms, it must be considered significant that the forms which occur at Swartkrans and Sterkfontein are represented in all the developed Oldowan assemblages, including the somewhat crude bifaces, the cleaver and the heavy duty pick. The assemblages from these sites, however, include a wider range of tools, particularly those in Upper Bed II, where modified and battered blocks and nodules are a common form and where burins, awls and *outils écaillés* also occur. In fact, in spite of the distance separating the two areas, there seems to be a similarity between the industries in South and East Africa. When the planned excavations of the implement-bearing breccias at Swartkrans and Sterkfontein have been carried out, so that a more comprehensive series of artefacts is available, much more detailed comparisons should be possible.

I thank Professor and Mrs R. Dart for their kindness and hospitality during my stay in Johannesburg, and Dr C. K. Brain, Mr B. Maguire and Mr A. Hughes for so generously giving their time to show me the sites and material and also for helping me in every way possible. Dr R. Mason also very kindly invited me to re-examine the Sterkfontein material.

Conceptual Model of the Bahamian Platform for the Last 135 Million Years

by
GEORGE W. LYNTS
Department of Geology and Marine Laboratory,
Duke University,
Durham, North Carolina 27708

The subsidence history of the Bahamian Platform points to a non-uniform rate of sea-floor spreading since the beginning of the Cretaceous. Lower Cretaceous rates of perhaps 5 cm/yr led to an active trench system at the boundary between the American and Caribbean lithosphere plates, and the rapid subsidence of the continental margin produced graben faults on the Bahamian Platform and normal faults in Cuba.

THE Hess–Dietz hypothesis of sea-floor spreading[1,2] has been tested over the past decade. The lithosphere plate–global tectonic model[3–5] requires an interrelationship between sea floors and continents and among continents because of interacting lithosphere plates. This model provided a relatively simple basis for formulating and testing hypotheses about the Earth, and Dott[6] therefore suggested that the study of well known land areas should "provide tests and refinements of postulated spreading histories".

Dietz *et al.*[7] and Lynts and Stehman[8] have suggested that the origin and history of the Bahamian region (Fig. 1) might be understood in terms of sea-floor spreading. I therefore propose to look at the sedimentary and tectonic history of the Bahamian Platform to see what it can reveal about the spreading history over the last 135 m.y.

A 4,445 m test well that bottomed out within the lower Cretaceous[9] was drilled on Andros Island (Figs. 1 and 2). Only shallow water carbonates and evaporites were encountered in the well[9,13], implying that the Bahamian Platform has subsided 4,445 m since lower Cretaceous time. The rate of subsidence of the Bahamian Platform has not been uniform over the past 120 m.y. (Fig. 3). Higher rates of subsidence prevailed during the lower Cretaceous and Palaeocene–Eocene, while lower rates occurred during the other epochs.

Vogt and Ostenso[14] suggest that continental margin subsidence seems to be related to the subsidence of oceanic crust after it leaves the crestal region of a mid-oceanic ridge. If so, then rates of continental margin subsidence should be related to rates of sea-floor spreading. Continental margins adjoining the Bahamian Platform should therefore record parallel subsidence histories. Fig. 3 shows that the subsidence history of the Florida Keys and Cape Hatteras is similar to that found on the Bahamian Platform.

Parallel subsidence histories on the Bahamian Platform and south-eastern North American continental margin support the validity of the Vogt–Ostenso[14] hypothesis and suggest that sea-floor spreading has not been steady state over the last 120 m.y. This history of sea-floor spreading seems to contradict the apparently steady state spreading history indicated by data from ocean basins. Heirtzler *et al.*[15] summarized magnetic anomaly data for all major ocean basins and pointed out that the anomalies suggest a steady state spreading history for the past 70 m.y. Percival[16] discussed the palaeontological evidence from drill holes in the South Atlantic and concluded that they supported a steady state spreading history for the Caenozoic. Data from continental margins in the western North Atlantic and circum-Pacific belt[6] suggest a non-steady state spreading history, while data from magnetic anomalies and deep sea drill holes in ocean basins support a steady state spreading history. Which of these data records the correct spreading history?

Schneider and Vogt[17] reviewed lines of evidence that may be used to recognize non-steady state sea-floor spreading. Phillips[18] and Vogt[19] noted that magnetic anomalies record a non-uniform spreading history for part of the Mid-Atlantic Ridge in, respectively, the North Atlantic and a region east of the Reykjanes Ridge. Le Pichon *et al.*[20], Van Andel *et al.*[21] and Fox *et al.*[22] reported that fracture zones in the Atlantic were not consistent with a steady state spreading history. Langseth *et al.*[23] suggested that the total heat released over the Mid-Atlantic Ridge seemed to be considerably lower than would be expected in a steady state model. Ewing and Ewing[24] described abrupt changes in sediment thickness between crests and flanks of mid-oceanic ridges that may record an episodic spreading history. Finally, Le Pichon[4] computed various lithosphere plate models for different magnetic anomalies that supported a non-steady state spreading history.

There seems to be sufficient evidence to reject the steady state model of sea-floor spreading and accept a non-uniform model. What, then, do the ocean basin magnetic anomalies[15] and deep sea drill holes[16] data imply? They seem to provide evidence against any long quiescent interval discussed by Ewing and Ewing[24], Schneider and Vogt[17] and Le Pichon[4].

The lithosphere plate model requires the rate of spreading to vary as the sine of the distance from pole of rotation[4].

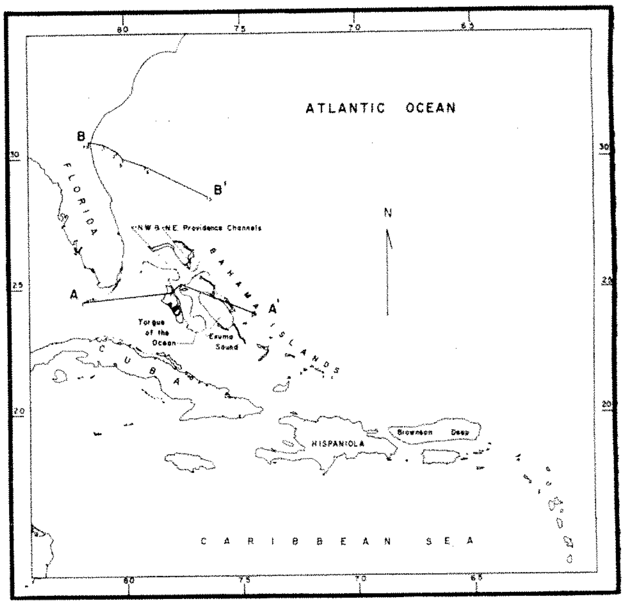

Fig. 1. Index map of Bahamian–Caribbean region. A–A′ and B–B′ are locations of cross-sections shown in Fig. 2.

The Vogt–Ostenso[14] hypothesis would result in a corresponding variation in continental margin subsidence with distance from lithosphere plate rotational pole. The North Atlantic model locates the lithosphere plate rotational pole in the vicinity of Greenland for the last 9 m.y.[3,4,22]. This would mean that the rates of spreading —and therefore the amount of subsidence—should decrease northward from the Bahamian Platform. Fig. 3 shows that there is less subsidence in the vicinity of Cape Hatteras than on the Bahamian Platform. Figs. 2 and 3 also show that there has been less subsidence in the western part of the continental margin than in its eastern extension.

The subsidence history of the western North Atlantic continental margin fits a lithosphere plate model of the Earth. It also provides further evidence that sea-floor accretion has been continuous, but not uniform over the past 135 m.y.

Le Pichon[4] constructed a model of the Atlantic at the time of magnetic anomaly 31 (Palaeocene). He argued that if most Cretaceous drift occurred during the lower Cretaceous (Bahamian subsidence history (Fig. 3) tends to support this interpretation), spreading half rates may have been as high as 6–8 cm/yr. He reported that spreading half rates greater than 5 cm/yr now cause thrusting, while half rates less than 5 cm/yr cause folding. What effects, if any, did spreading rates of this magnitude have on the region ?

The Puerto Rico Trench[25] (Brownson Deep, Fig. 1) is south-east of the Bahamian Platform. It is an anomalous trench in that it occurs in a region with spreading half rates of less than 5 cm/yr[4,18]. Seismic data of Drake *et al.*[26] imply that the mantle east of the Bahamas has a depth and configuration similar to that found beneath the Puerto Rico Trench. This may represent either a separate trench or an extension of the Puerto Rico Trench that has filled with sediment. The Puerto Rico Trench does not seem to be as active seismically as its Pacific counterparts, and the Bahamian Platform is not seismically active[27]. This suggests that the Puerto Rico Trench is a relict feature.

Deep entrenchments[28–31] dissect the Bahama Banks (Fig. 1). Gravity and seismic data suggest that these entrenchments have a tectonic origin[31,32], and Talwani *et al.*[31] called on graben faulting for their origin. Many workers have suggested that the Florida Straits also have a graben fault origin[33–37]. Because this region is not now tectonically active[27] and the entrenchments have been deep water features since at least the early Tertiary[8,38], they may have originated during either the Cretaceous or early Tertiary. Caenozoic subaqueous erosion and deposition have modified them to their present topographic expression[36,38,39].

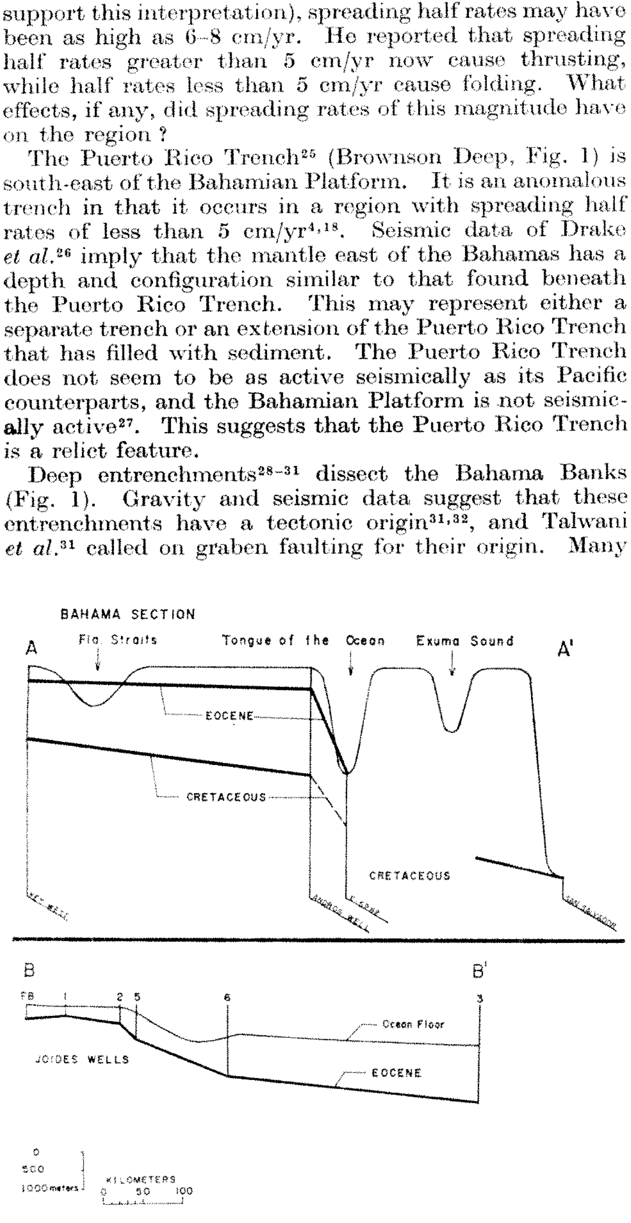

Fig. 2. Diagrammatic cross-sections of traverses from Florida Keys to eastern Bahamian region[8–10] (A–A') and JOIDES[11] drill holes on the Florida continental margin (B–B').

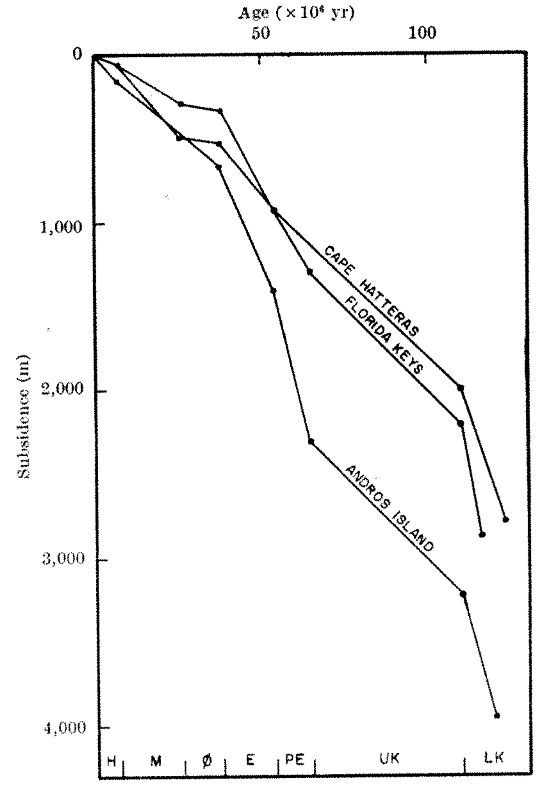

Fig. 3. Subsidence plotted against time. Curves represent record of subsidence through time. Andros Island data from Spencer[9]. Florida Keys data from Maher and Applin[10]. Cape Hatteras data from Swain[13]. H, Holocene–Pliocene; M, Miocene; Ø, Oligocene; E, Eocene; P, Palaeocene; UK, upper Cretaceous; LK, lower Cretaceous.

Goodell and Garman[12] proposed a causal relationship between Cuban orogenic activity and Bahamian Platform tectonic-subsidence history. G. W. L. and Stehman[8] also recognized this relationship, but rather than calling it causal they suggested a parallel relationship resulting from sea-floor spreading. Orogenic activity in Cuba was most intense during the lower Cretaceous and late Cretaceous to middle Eocene[40–42]. Most faults in Cuba are of a high angle[40]. Volcanic activity began, and was most intense, during the early Cretaceous, but continued into the Eocene[40]. Most of the volcanics were basic, but during the upper Cretaceous ultrabasics (harzburgite, lherzolite, dunite and anorthosite) were intruded[40]. Engel and Fisher[43] suggested that lherzolite may be an upper mantle rock exposed at the Earth's surface by faulting.

Thus although the Bahamian region is not now tectonically active, it may have been active during the late Mesozoic and early Caenozoic. Tectonic activity was probably greatest during the lower Cretaceous and Palaeocene–Eocene.

The tectonic framework discussed above leaves us with the apparently anomalous association of compressional (trenches) and tensional (graben and normal faults) features that may be dynamically related. I believe that a model of the Bahamian region may be developed to explain this dynamic relationship logically.

The JOIDES deep sea drilling programme data[44] and quiet magnetic zone[45] suggest that the history of the Bahamian Platform extends back into the Jurassic, and

possibly into the Palaeozoic. Present data provide direct evidence of the tectonic-subsidence history of this region back into the Cretaceous. The model will therefore only be applicable back to 135 m.y.

The subsidence history of the Bahamian Platform (Fig. 3) and models constructed by Le Pichon[4] indicate a higher rate of sea-floor spreading during the lower Cretaceous than at present (6–8 cm/yr). As a result, the Puerto Rico Trench and the proposed trench east of the Bahamas would be areas of active thrusting of the American lithosphere plate under the Caribbean plate (Fig. 4). The region west of the trench system, the Bahamian Platform, was subsiding rapidly and the easternmost part of the platform was being dragged downward into the mantle, giving rise to tension to the west (Fig. 4). The tension resulted in the development of graben faults on the Bahamian Platform and normal faults in Cuba. This may be visualized as analogous to the formation of crevasses in a glacier. The normal faults created avenues along which basic lavas rose. The volcanic and associated orogenic activity resulted in the Antillean island arc system.

The rate of sea-floor spreading decreased during the upper Cretaceous (Fig. 3) and the trench system became inactive; the postulated trench east of the Bahamas began to fill with carbonate sediments. During the Palaeocene and Eocene the spreading rate increased, but the rate was probably not high enough to reactivate the trench system. Rates of drift decreased markedly during the Oligocene but increased during the Miocene to half rates[18] of about 1·7 cm/yr. There was another decrease in spreading during the Pliocene (6 m.y. ago) to its present half rate of 1·25–1·4 cm/yr[18]. This rate of spreading is now expressed by deformed sediments on the Barbados Ridge[19,46] and "horizon A" outcrop area[47].

The model implies that all the tectonic-subsidence history of the Bahamian Platform–Cuba–South Florida region can be explained in terms of a lithosphere plate-global tectonic model of the Earth's crust. Included in the model is the dynamic relationship of compressional and tensional structures (Fig. 4). The dynamic relationship of trenches and normal faults may explain the development of volcanic island arc systems landward of continental margin-trench systems[19].

This study was partially supported by the US National Science Foundation. C. F. Stehman and L. K. Glover assisted in drafting the figures, and I thank M. M. Ball, R. S. Dietz, J. Dorman, B. C. Heezen, T. Saito and R. E. Sheridan for valuable discussions.

LETTERS TO THE EDITOR

PHYSICAL SCIENCES

Origin of the Ultra-short Period Binary WZ Sagittae

THE recent discovery of several binaries with periods in the range of a few hours has raised the problem of their past evolution. Three eclipsing binaries are in that group: the old nova WZ Sge, EX Hya and VV Pup. I shall confine myself to the case of WZ Sge, for which the largest amount of data is available. Krzeminski and Kraft[1] have shown that the system is composed of a DA white dwarf, for which they estimate a mass $M=0{\cdot}59\ M_\odot$, and a secondary of mass $m=0{\cdot}03\ M_\odot$. The radii are $R\simeq 0{\cdot}87\times10^9$ cm and $r\simeq 7\times10^9$ cm, and the separation $a=3{\cdot}7\times10^{10}$ cm.

If we assume that the secondary is a completely degenerate star and use the mass–radius relation recently calculated by Zapolsky and Salpeter[2] for such stars, we find that the star is composed of almost pure hydrogen. This indicates that, in its past, it has never been massive enough to burn hydrogen.

The primary is a white dwarf of mass $M=0{\cdot}59\ M_\odot$ and current ideas on stellar evolution assume that it is the remnant of a more massive star which once burned hydrogen and became a red giant with a radius greater than, say, 100 $R_\odot$. It lost a considerable amount of mass and left a remnant that is the present white dwarf.

Let us take the initial separation of the two stars to be less than the radius of the primary in its giant phase. The secondary was then, for a time, surrounded by a giant envelope. It accreted matter at a rate estimated by Bondi and Hoyle[3] as

$$\dot{m}=2\pi\alpha G^2m^2V^{-3}\rho \tag{1}$$

where $\alpha=1{\cdot}25$ and V is the orbital velocity of the secondary. If we assume that the matter collected has, on the average, no angular momentum, we have

$$L=mvr=1{\cdot}023\times10^{50} \tag{2}$$

I finally assume, for the sake of simplicity of calculation, that the secondary moves under the gravitational attraction of a mass equal to the actual mass of the white dwarf. That gives $V=(GM/r)^{1/2}$. These three relations give for the change in radius

$$\frac{1}{r}-\frac{1}{r_0}=\frac{4\pi\alpha L}{M^2}\rho t$$

where r_0 is the initial and r the present separation of the stars. In the extreme case $r_0=\infty$, we have

$$t(\text{yr})=\frac{0{\cdot}74\times10^{-3}}{\rho}$$

If we take as a typical value of the density $\rho=10^{-6}$ we get $t\simeq10^3$ yr. This time is much shorter than the lifetime of a giant star. If the secondary had been, for a substantial length of time, inside the envelope of the giant, it would have accreted matter, become closer to the primary and would eventually have been captured. We know this did not happen.

The secondary was then, almost at all times, outside the envelope of the primary. Let us calculate the time required for gravitational waves to change their separation by a substantial amount. If that separation were at one time, say, a hundred times its actual value, by Kepler's third law we would have $a^3P^{-2}=4\pi^2(M+m)$ and the period would be a thousand times the actual period. The time required for a substantial change in r is of the order of magnitude of the binary collapse time, given by Paczynski[4]

$$T_0(\text{yr})=3{\cdot}22\times10^{-3}\,\frac{(M+m)^{1/3}}{Mm}\,P_0^{8/3}$$

where P_0 is the period in seconds and M and m are in solar masses. The value of T_0 for the present configuration is $1{\cdot}12\times10^9$ yr. The collapse time from a position where $P=1{,}000\ P_0$ is $10^8\ T_0$, much longer than the age of the universe.

There is another way to place the secondary in its present position. Suppose the giant primary ejected matter with very low velocity until only the present mass remained. Part of this matter was accreted by the secondary and the mutual separation decreased, but the secondary was always outside the envelope of the primary.

Let us evaluate the changes in mass and separation of both stars. The secondary mass will be given by equation (1), and the constancy of angular momentum by equation (2). We take a very simple model for mass loss in which the rate is given by

$$R=4\pi r^2\rho c \tag{3}$$

Here ρ is the density of matter at distance r and c is its velocity, taken to be constant.

Finally, the orbital velocity of the secondary is given by

$$V=\left[\frac{G(M_0-Rt)}{r}\right]^{1/2} \tag{4}$$

where M_0 is the mass of the primary at $t=0$.

Elimination of V and ρ using equations (3) and (4) gives

$$\dot{m}=\frac{\alpha RG}{2cL}\ \frac{m^3}{(M_0-Rt)} \tag{5}$$

and

$$r=\frac{L^2}{m^2G(M_0-Rt)} \tag{6}$$

Let us assume that the mass loss starts with $M=M_0$, $m=m_0$ and $r=r_0$ and ends with $M=M_1=0{\cdot}59\ M_\odot$, $m=m_1=0{\cdot}03\ M_\odot$ and $r=r_1=3{\cdot}7\times10^{10}$ cm. Integration of equations (5) and (6) between these values gives

$$\frac{1}{m_0^2}=\frac{1}{m_1^2}+\frac{\alpha G}{cL}\ln\left(\frac{M_0}{M_1}\right) \tag{7}$$

and

$$r_0=\frac{L^2}{GM_0}\left[\frac{1}{m_1^2}+\frac{\alpha G}{cL}\ln\left(\frac{M_0}{M_1}\right)\right] \tag{8}$$

It is interesting to note that equations (7) and (8) are independent of the duration of the mass loss.

The ratio of initial to final separation is

$$\frac{r_0}{r_1}=\left(\frac{M_1}{M_0}\right)\left[1+\frac{m_1^2\alpha G}{cL}\ln\left(\frac{M_0}{M_1}\right)\right] \tag{9}$$

If we substitute the actual values $r_1 = 3{\cdot}7\times 10^{10}$, $L = 1{\cdot}015\times 10^{50}$ and $m_1 = 5{\cdot}967\times 10^{31}$ and if we take $\alpha = 1{\cdot}25$ and $M_0/M_1 = 5$, we have

$$\frac{r_0}{r_1} = 0{\cdot}20\left[1+\frac{4{\cdot}7\times 10^6}{c}\right]$$

which for $c \gg 4{\cdot}7\times 10^6$ reduces to $\dfrac{r_0}{r_1} \simeq \dfrac{10^6}{c}$

If $c \simeq 10^3$ cm s^{-1}, we have $r_0 \simeq 10^3\ r_1$. That places the secondary well outside the region to be occupied by the envelope of the primary. Equation (9), then, gives for the initial secondary mass $m_0 = 0{\cdot}87\times 10^{30}$ g.

These values for the initial separation and mass are comparable to the values for Jupiter and the Sun. If the Sun becomes a giant star and loses a considerable fraction of its mass at very low flow velocity, part of it would be collected on Jupiter, which would then move close to the Sun. Their final configuration would probably not be very different from the actual one for the binary star SW Sge.

Bremsstrahlung Radiation in an Intense Magnetic Field and Emission from Pulsars

Simon and Strange recently argued[1] that one of the processes (bremsstrahlung in the 0→0 transition in a magnetic field) which we proposed[2] as the chief mechanism of emission from pulsars cannot give rise to a negative absorption coefficient. They based their argument on an existing formula for the absorption coefficient valid only for synchrotron radiation. Further, their expression for the emissivity was found by us to be applicable only to the high quantum number case. When the correct formula for the absorption coefficient was used in conjunction with the emissivity valid for the 0→0 transition, we found that the absorption coefficient can become negative and amplification of electromagnetic waves is possible from the 0→0 bremsstrahlung process.

First we shall show that the result of Simon and Strange, equation (3) of their paper,

$$\alpha_\omega = \frac{8\pi^3 c}{\omega^2}\ \frac{n(\theta)\cos\theta}{n_r^2}\int_{-\infty}^{\infty} f(p_z)\,\frac{\mathrm{d}Q_\omega}{\mathrm{d}p_z}\,\mathrm{d}p_z$$

cannot be correct as it gives a zero absorption coefficient for a gas in equilibrium, independent of any absorption process. (α_ω = absorption coefficient, ω = frequency, p_z = electron momentum parallel to the field, $f(p_z)$ = electron distribution function, θ = angle of emission with respect to the field, Q_ω = rate at which energy is emitted spontaneously by the electron with momentum between p_z and $p_z + \mathrm{d}p_z$ at the frequency ω, per $\mathrm{d}\omega$, per unit solid angle, in the direction θ, and $n(\theta)$ and n_r are refractive indices.) Q_ω depends on the absolute value of p_z and is therefore an even function of p_z. Consequently $\mathrm{d}Q_\omega/\mathrm{d}p_z$ is an odd function of p_z. In equilibrium $f(p_z)$ is an even function and hence α_ω in equation (3) of ref. 1 vanishes identically, independent of any absorption process. This clearly violates basic laws of thermodynamics.

The origin of this inconsistency can be traced to Simon and Strange's improper application of equation (2.54) of ref. 3 of their paper[3]. This result is valid only for classical synchrotron radiation, derived from the master equation (2.36) after using equations (2.46) and (2.50) which are applicable only to synchrotron radiation and not to the bremsstrahlung process. Equation (2.50) describes the momentum conservation condition which is absent in the bremsstrahlung case, for the nucleus can absorb momentum without absorbing energy. The improper application of equation (2.54) leads to the result of zero absorption coefficient.

In order to derive the correct equation, we refer to the master equation (equation (2.36) of ref. 3) modified for a one-dimensional gas

$$\alpha_\omega = \frac{8\pi^3 c^2}{n_r^2\hbar\omega^2}\int_{-\infty}^{\infty} Q_\omega(p')[f(p)-f(p')]\,\mathrm{d}p' \qquad (1)$$

where p and p' are electron momenta before and after absorbing the photon $\hbar\omega$. The energy conservation law requires that

$$\hbar\omega + \frac{p_z^2}{2m} = \frac{p_z'^2}{2m} \qquad (2)$$

Because $\hbar\omega \ll p_z^2/2m$, we can expand $(f(p_z)-f(p_z'))$ and write

$$f(p_z)-f(p_z') = \frac{\partial f(p_z')}{\partial p_z'}\,\Delta p_z \qquad (3)$$

$$\Delta p_z = p_z - p_z' = -\frac{2m\hbar\omega}{p_z+p_z'}$$

Therefore

$$\alpha_\omega = \frac{8\pi^3 c^2}{n_r^2\,\omega^2}\cdot 2m\int_{-\infty}^{\infty}\frac{Q_\omega(p_z')}{p_z+p_z'}\ \frac{\partial f(p_z')}{\partial p_z'}\,\mathrm{d}p_z' \qquad (4)$$

By partial integration and rearranging terms, we find the correct form of equation (3) of Simon and Strange's paper

$$\alpha_\omega = \frac{8\pi^3 c^2}{n_r^2\omega^2}\ 2m\int_0^{\infty}\left[f(p_z')\frac{\partial}{\partial p_z'}\left(\frac{Q_\omega(p_z')}{p_z'-p_z}\right)+\right.$$
$$\left. f(-p_z')\frac{\partial}{\partial p_z'}\left(\frac{Q_\omega(p_z')}{p_z'-p_z}\right)\right]\mathrm{d}p_z' \qquad (5)$$

which no longer vanishes when $f(p_z) = f(-p_z)$. The criterion for a negative absorption coefficient in the case $f(-p_z) \ll f(p_z)$ (which corresponds to a population inversion in terms of a coherent streaming motion with respect to the medium in the $+p_z$ direction) is

$$\frac{\partial}{\partial p_z'}\left(\frac{Q_\omega(p_z')}{p_z'+p_z}\right) < 0 \qquad (6)$$

or $Q_\omega(p_z)$ must not rise faster than the first power of p_z.

The absorption coefficient quoted by Simon and Strange has been found by us recently to be correct only in the high quantum number regime and is totally inapplicable to the 0→0 transition. The correct expression for the transition probability in the 0→0 transition is:

$$w(p_{z1}\omega) \simeq C\,\frac{n_r}{\omega|p_z|}\quad g(\omega) \qquad (7)$$

where $g(\omega)$ is a slowly varying function and C is a constant. The presence of p_z in the denominator is purely the effect of the density of the final state of a one-dimensional particle. As is well known, the density of states of a one-dimensional particle, $\rho(\varepsilon)$, is

$$\rho(\varepsilon) = \frac{\mathrm{d}p}{\mathrm{d}\varepsilon} \propto \frac{1}{p} \qquad (8)$$

Accordingly

$$\frac{\mathrm{d}}{\mathrm{d}p_z}\left(\frac{Q_\omega(p_z)}{p_z}\right)$$

is negative and the absorption coefficient can be negative. Laser amplification of radiation can therefore take place.

We have applied equation (7) to electromagnetic wave amplification in our model and found that the spectrum of the resultant coherent radiation is proportional to $\nu^{-\alpha}$, where α is of the order unity but α is a function of various parameters associated with the neutron star. This type of spectrum agrees roughly with that observed. A full account of this theory is being prepared for publication.

Possibility of a Terrestrial Component in the Doppler Shifted Zodiacal Light

LIGHT scattered off particles in circum-terrestrial space may make an appreciable contribution to the zodiacal glow. Just how significant this contribution might be unfortunately is still unknown. The information we have comes directly from the infrared observations by Petersen[1] and McQueen[2]. These show that an appreciable portion of the dust must be in circum-solar orbits, some of it quite near the Sun. Direct observations on the circum-terrestrial components, however, are still ambiguous, despite extensive particle detection experiments from space probes[3]. Such experiments have been largely sensitive to particles larger than those thought responsible for the zodiacal glow.

For this reason, the recent observations of Reay and Ring[4] are welcome, and though they are not specific enough, as yet, to permit conclusions about the circum-terrestrial particles, they indicate that the spectroscopic method is intrinsically sensitive enough to permit an early decisive test.

Our aim in this letter is first to show that the use of Mie theory does not appreciably change the conclusions already drawn by Bandermann and Wolstencroft[5] and by Reay[6], so that an appreciably better fit to the experimental data could not be expected even if quite unusual particle properties or orbits were taken seriously. This leads to our second point, which assumes a certain circum-terrestrial dust component and then predicts that the low velocity Doppler shifts observed at high elongations will be confirmed by more detailed observations and will, in fact, be present both in the morning and evening zodiacal glow.

The difference between a circum-terrestrial dust containing model and the pure interplanetary dust model, for which James[7] has computed characteristic Doppler shift curves, is large enough so that present techniques seem capable of making a distinction.

If an appreciable fraction of the dust is concentrated near the Earth, one would expect the value of the wavelength shift to be below the theoretical curve at elongations of the order of 70°, while, as James has shown, the wavelength shift for an entirely circum-solar cloud exhibits no such drop.

Like the previous authors[5,6] we assume an effective Doppler shift

$$<\delta\lambda> = \frac{\int \delta\lambda(B)\,\mathrm{d}B}{\int \mathrm{d}B}$$

where $\delta\lambda(B)$ is the wavelength shift and $\mathrm{d}B$ the surface brightness due to individual volume elements along a line of sight through the zodiacal dust cloud. $<\delta\lambda>$ is the expected averaged shift obtained from direct observations. Ingham[8] as well as Reay[6] considered that the phase function which determines $\mathrm{d}B(\theta)$ for phase angle θ is the sum of phase functions for reflected and diffracted light. Such a function, however, is not identical with that obtained from Mie theory, and we therefore consider whether appreciable changes in results are to be expected on that basis. We take a phase function

$$F(\theta,\, x,\, m) = \tfrac{1}{2}\, i_1\,(\theta,\, x,\, m) + i_2\,(\theta,\, x,\, m)$$

where $x = 2\pi a/\lambda$ is the size parameter, dependent on particle radius a, and m is the refractive index. If $C\,(x,\, m)$ is chosen as the scattering cross-section and $\varphi\,(x)$ represents the particle size distribution function, the phase function for the polydisperse, optically thin cloud becomes

$$\Psi(\theta) = \frac{\lambda^2 \int_{x_1}^{x_2} F(\theta,\, x,\, m)\;\varphi\,(x)\;\mathrm{d}x}{\pi \int_{x_2}^{x_1} C\,(x,\, m)\;\varphi\,(x)\;\mathrm{d}x}$$

The phase function $\Psi(\theta)$ has a characteristic minimum at $\theta \sim 90°$, which is very pronounced for dielectric particles. At elongations ε of about 90°, particles relatively distant from the Earth therefore contribute appreciably to the Doppler shift, because $\theta \gg 90°$ for these grains. This makes the value of $<\delta\lambda>$ practically independent of the physical properties assumed for the scatterers.

In Fig. 1 we show the Doppler shift as a function of elongation, computed for circular orbits about the Sun.

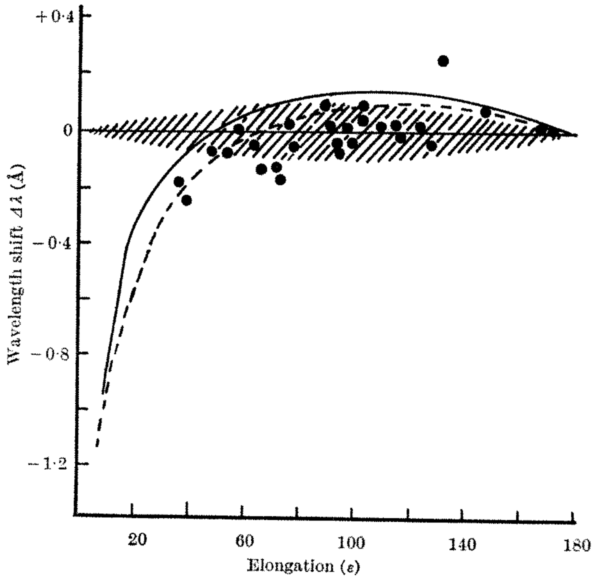

Fig. 1. Wavelength shift $\Delta\lambda$ at the evening zodiacal light as a function of elongation ε in degrees. The dashed curve represents James's results for isotropically scattered particles. The full line represents our results for Mie scatterers. The hatched area represents circum-terrestrial grains with peak elongations somewhat arbitrarily chosen as ±6 km s^{-1}. The full points are data gathered by Reay and Ring.

The assumed space density distribution varied as r^{-2} with increasing distance r from the Sun. We took $\varphi(x) = (x/x_0)^{-4}$ with size limits $x_1 = 0{\cdot}8$ and $x_2 = 10$. The refractive index was that of silicate-like particles with small absorption, $m = 1{\cdot}50 - 0{\cdot}1\,i$. This gives the full curve, while the broken curve represents the results of James for isotropic scattering. Both these curves are drawn for the evening zodiacal light, and they do not seem to be capable of explaining the negative value of $<\delta\lambda>$ obtained by observations[4]. Those are shown by the dots in Fig. 1.

If we assume that the observations are correct, then the values obtained at elongations in excess of $\varepsilon > 70°$ may represent the dominance of dust near the Earth. This would be the case if an areal density of scatterers were assumed such that

$$\frac{1}{4\pi}\int_0^R S\,\sigma\,N(s)\,\mathrm{d}s \sim 3\times10^{-10}\,\mathrm{W\ cm^{-2}\ sr^{-1}}$$

This expression merely states that if $N(s)$ is the number of particles per unit volume, at distance s from the Earth, and R is the distance from the Earth beyond which contributions can be neglected, then the total observed flux, given on the right-hand side of the equation, should equal the scattered sunlight integrated along a column out to distance R. We have called the particle cross-section σ and assumed that they scatter isotropically[9]. S is the solar constant $\sim 0{\cdot}14$ W cm^{-2}.

If we assume $N(s)$ to be constant out to distance R, we obtain the simple relation

$$N\sigma \sim 3\times10^{-8}\,R^{-1}\ \mathrm{cm^2\ cm^{-3}}$$

Because absorption of radiation and predominance of forward scattering have been neglected, the actual value of the areal density may be half an order of magnitude or so higher. Even so, if we choose R to have a value of order 10^{10} to 10^{11} cm, we obtain $N\sigma$ values in the range $10^{-17\cdot5}$ to $10^{-18\cdot5}$ cm. These do not seem to be ruled out by present observations.

We may also compute the mass infall rate from such dust, if the circum-terrestrial component reached as far as the Moon. The mass accreted through action of the Poynting–Robertson drag would then amount to roughly 10^3 kg each day for micron sized grains and less for submicron sized particles. This is conservative with respect to figures quoted by Hawkins[3] for infall rates onto the Earth.

With such a circum-terrestrial concentration, the plot of wavelength shift against elongation would take on the form of the shaded portion in Fig. 1. This region can be expected to be wide because both prograde and retrograde circum-terrestrial orbits are likely. As Bandermann and Wolstencroft have pointed out, these have a sin ε dependence for velocity shifts as a function of elongation. The spread in velocities due to this effect would be of the order of a few kilometres per second for typical grains in the space between Earth and Moon.

The 11 Canis Minorids—a New Meteor Stream probably associated with Comet Mellish 1917 I

WE have detected a new meteor stream complex, active between solar longitudes $\lambda_\odot = 257°$ and $262°$, with a true radiant some 3° north-west of 11 Canis Minor. The stream was first recorded on the morning of December 10, 1964. During visual watches with a richest field 5-inch telescope, positional data were recorded for meteors in the range from magnitude +6 to +12 (ref. 1). Five meteors, originally classified as sporadic, were found to be radiating from an observed centre at right ascension $(\alpha) = 115{\cdot}8 \pm 1{\cdot}2°$, declination $(\delta) = +13{\cdot}0 \pm 0{\cdot}8°$. Statistical tests indicate that the probability of this radiant being due to the chance lining up of sporadic meteors is only 1 in 10^4. No velocity measurements were available and so orbital elements were computed using Porter's method[2], initially assuming parabolic motion. Corrections to the observed radiant for diurnal aberration and zenithal attraction were small, the resulting parabolic orbit being highly inclined with a remarkably small perihelion distance. The true radiant and preliminary orbit are given in Table 1.

Table 1. TRUE RADIANT AND PRELIMINARY ORBIT

R.A.	$115{\cdot}1 \pm 1{\cdot}2°$	
Dec.	$+12{\cdot}4 \pm 0{\cdot}8°$	
i	$89 \pm 17°$	1950·0
ω	$158{\cdot}1 \pm 1{\cdot}4°$	
Ω	$78{\cdot}476 \pm 0{\cdot}002°$	
q	$0{\cdot}036 \pm 0{\cdot}009$	

The longitude of the true radiant is close to the anti-helion point making the computed orbital elements, particularly the orbital inclination i and to a lesser extent the longitude of the perihelion ω, extremely sensitive to changes in radiant position. The computed orbit is hence relatively indeterminate in i despite an accurate radiant determination.

Published catalogues of photographic meteors[3-9] have been searched for possible stream members, yielding the four meteors in Table 2. These were the only meteors recorded with radiants near the expected area from $\lambda_\odot = 250°–270°$. In computing mean characteristics, the more accurate meteor No. 4 has been weighted × 2. The mean orbit of these photographic meteors bears a considerable resemblance to the telescopic orbit and, like the latter, is also relatively indeterminate in i. Using the mean semi-major axis from the photographic meteors $a = 1{\cdot}90$, the observed telescopic radiant has been used to compute an ellipse, shown in Table 3 as solution 1, together with the photographic ellipse. Reducing the value of the assumed telescopic meteor velocity in this way drastically reduces i and increases the value of q. A further possible solution is to reduce this velocity further to a value producing $i = 32{\cdot}9°$, the mean photographic inclination. This telescopic meteor orbit is also shown in Table 3, as solution 2, with q now near the photographic value, but with $a = 1{\cdot}17$.

Such an arrangement, with the less massive telescopic meteors having an orbital period shorter than the photographic meteors, is consistent with the operation of the Poynting–Robertson effect for some time on an initially compact stream with larger period. We regard this second telescopic solution as being the most likely and conclude

* Longitude of closest approach.

that the photographic and telescopic orbits represent the same meteor stream, the photographic meteors confirming the existence of the stream observed visually.

The 11 Canis Minorid meteor stream is remarkable in being only the second case of a stream with $q < 0·1$ AU, the other case being the δ Aquarids ($q = 0·061$ AU) (ref. 10). Orbits of this type do not possess long term stability. Because of dispersive and erosive forces, this new stream has a future lifetime of at most 10^5 yr. A full discussion of these effects will appear elsewhere[11].

The catalogue of known cometary orbits[12] reveals one comet with an orbit similar to the 11 Canis Minorids—Comet Mellish 1917 I. This is one of the nineteen comets with elliptical orbits passing within 0·1 AU of the Earth's orbit[13]. The comet orbit is quoted in Table 3 with an ascending node $\Omega = 88·0°$. This is near the meteor nodes $\Omega = 78·5°$ and 80·2°, but the longitude of the comet's closest approach to the Earth's orbit, where one would expect to be able to detect meteor activity, is $\lambda = 81·9°$, very close to the observed meteor orbit nodes. The separation of the orbits of the comet and the Earth at this closest approach is only 0·061 AU. The orbital inclinations of the comet and meteor orbits are almost identical, but the stream perihelion averages $q = 0·074$ AU, less than half of the comet's $q = 0·190$ AU, making the difference in ω as high as 36°. But a stream with such a small q has elements which are very sensitive to perturbations and dispersive and erosive forces. We believe the differences between the comet and meteor orbits may be explicable on these grounds and that the evidence is good for the 11 Canis Minorids being associated with Comet Mellish 1917 I. This suggested association is similar in many respects to those suggested for the Orionids with Halley's Comet[14-16] and the Ursids with Comet Tuttle 1939 X (refs. 17 and 18).

We request groups and individuals who record meteors using either photographic or radar methods to look for evidence of this shower.

We thank Dr P. J. Message and Mr H. B. Ridley for discussions and the Science Research Council, Professor J. M. Cassels and Dr J. Read (Oliver Lodge Laboratories, University of Liverpool) for the use of the IBM 360/65 computer.

Quantization of Wheeler–Feynman Electrodynamics

IN a recent letter, Katz, Ornan and Schwartz[1] (KOS) have argued that our treatment of spontaneous emission[2] deviates from the classical Wheeler–Feynman (WF) prescription[3]. They base their argument on the form of the interaction term

$$e_b \int A^{(a)}_{\mathrm{ret}}[b(t)] \cdot \dot{b}(t)\mathrm{d}t \qquad (1)$$

where $A^{(a)}_{\mathrm{ret}}$ is the retarded potential arising from the motion of the source particle a, and $b(t)$ is the path of a typical absorber particle b. Written in this form (1) denotes the retarded effect of particle a on particle b. KOS, however, rewrite (1) in the form

$$\begin{aligned} e_b \int A^{(a)}_{\mathrm{ret}}[b(t)] \cdot \dot{b}(t)\mathrm{d}t &= 2e_a e_b \iint \delta(S^2_{\mathrm{AB}})\dot{a}(t') \cdot \dot{b}(t)\mathrm{d}t\mathrm{d}t' \\ &= e_a \int A^{(b)}_{\mathrm{adv}}[a(t')] \cdot \dot{a}(t')\mathrm{d}t' \qquad (2) \end{aligned}$$

and argue that (2) represents the advanced effect of b on a.

This argument would have been correct if we were dealing with a two-particle system. This, however, is not the case. In (1), $A^{(a)}_{\mathrm{ret}}[b(t)]$ represents not just the direct retarded effect of a, but also the retarded effect produced by other particles, $c, d, \ldots$, in the future absorber which have been excited by the retarded potential of a. The use of the simple delta function in (2) is therefore not valid. The effect of other particles in the future absorber is to attenuate and change the phase of the original retarded disturbance emanating from a. All these effects cannot be included in an equality of the type (2).

We now come to the connexion between the quantum and classical versions of the theory of direct interparticle action. Quantum theory is necessarily richer than the classical theory. The interference of probability amplitudes in the former leads to results that have no analogues in the latter theory. When $\hbar \to 0$, however, the quantum theory must lead to the classical theory. The following remarks show that this happens in the treatments given in refs. 2 and 3.

The total field acting on particle a at time $t=0$ in the classical theory is given by

$$\tfrac{1}{2}\sum_{b\neq a}(F^{(b)}_{\text{ret}}+F^{(b)}_{\text{adv}})=\tfrac{1}{2}\sum_{\substack{b\neq a\\ t<0}}(F^{(b)}_{\text{ret}}+F^{(b)}_{\text{adv}})+R^{(a)} \qquad (3)$$

In (3) the left hand side denotes the field exerted by all particles $b\neq a$. Each particle acts on a via retarded and advanced fields. The first term on the right hand side denotes the part due to the past half of the universe ($t<0$), whereas $R^{(a)}$ denotes the part due to the future half ($t>0$). In a perfect future absorber $R^{(a)}$ is given by

$$R^{(a)}=\tfrac{1}{2}\sum_{\substack{b\\ t<0}}(F^{(b)}_{\text{ret}}-F^{(b)}_{\text{adv}}) \qquad (4)$$

$R^{(a)}$ is the classical response of the universe. The term $b=a$ in (4) leads to radiative damping. This is the classical WF theory.

In the quantum calculation of ref. 2, a path integral approach is followed. We can no longer calculate the unique path followed by a, we can only calculate probabilities for different paths. This necessarily leads to the squaring of the amplitude and hence to an influence functional $F[a,a']$ involving paths and conjugate paths (compare ref. 2). The quantum analogue of (4) expressed in terms of potentials is

$$R^{(a)}=\tfrac{1}{2}\sum_{\substack{b\\ t<0}}[A^{(b)}_{\text{ret}+}-A^{(b)}_{\text{adv}+}]+\tfrac{1}{2}\sum_{\substack{b\\ t<0}}[A'^{(b)}_{\text{ret}-}-A'^{(b)}_{\text{adv}-}] \qquad (5)$$

where $A^{(b)}_{\text{ret}+}$ denotes the positive frequency part of $A^{(b)}_{\text{ret}}$. The other quantities in (5) are similarly defined. The primed quantities arise from conjugate paths. The important point is that in a cold environment (provided by the expanding universe) paths contribute positive frequencies and conjugate paths negative frequencies. The appearance of paths and conjugate paths is an indication of the richness of quantum theory in comparison with the classical one, and is responsible for the variety of phenomena in quantum electrodynamics.

In the limit $\hbar\to 0$, paths and conjugate paths coincide and we arrive at (4). Thus the classical Wheeler–Feynman radiation reaction formula follows from the quantum calculation in the limit $\hbar\to 0$.

Desert Stream Channels resembling Lunar Sinuous Rilles

SOME of the sinuous rilles on the Moon seem to have been formed by fluid flow, but what the fluid was is unknown. Lava[1,2], ash[3], water[4,5], or combinations such as mud, or water under or over permafrost (refs. 6–8 and unpublished work of Hapke and Goldberg), have been suggested (Fig. 1).

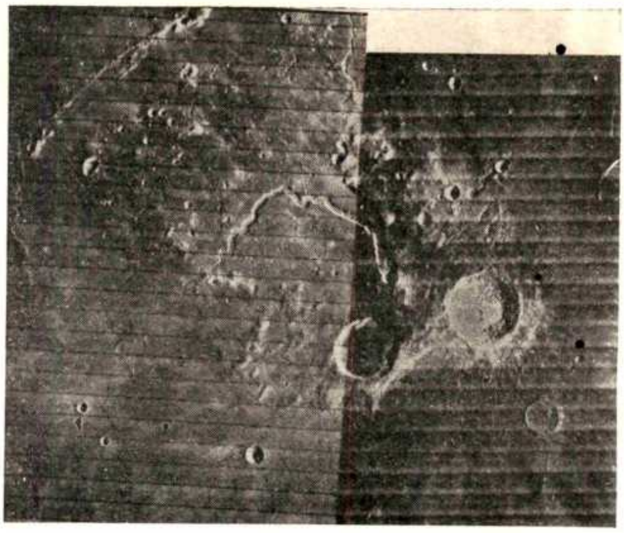

Fig. 1. Aristarchus region of Moon. Main channel of Schröter's Valley is 3 to 5 km wide. Lunar Orbiter IV, Frames H-150 and H-157.

Air photographs of the Mojave Desert geomorphic province of southern California show several stream channels that resemble certain lunar sinuous rilles. We have examined two of these in the Deadman Lake Quadrangle approximately 12 miles north of Twentynine Palms, to find how they are formed. The desert rilles are on alluvial slopes where windblown sand is present so that the intermittent streams emerging from canyons are forced to transport fine sand in addition to their normal burden of alluvium. The meandering channels are then partly covered by more windblown sand, much of it resting at the angle of repose typical for desert dunes. Thus all shapes are gently rounded and the channel banks are hidden except for occasional outcrops of loose or weakly consolidated sand, gravel and angular cobbles. These stream beds look quite unlike ordinary desert washes, but are strikingly similar to lunar rilles.

Fig. 2 shows the desert rilles, and Fig. 3 some examples of normal desert stream beds. The California rilles are about the same size as the smallest lunar rilles identifiable; they are 3–5 km long and up to 50 m deep at the upper end. Rilles on both the Earth and Moon differ from ordinary alluvial stream beds in that they lack tributaries, branches or braiding, and they taper away to nothing at the downstream end with no evidence of a delta. Some parts of the desert rilles (Fig. 4) have the same kind of channel banks as an ordinary wash or arroyo, including vertical walls where the alluvium is sufficiently con-

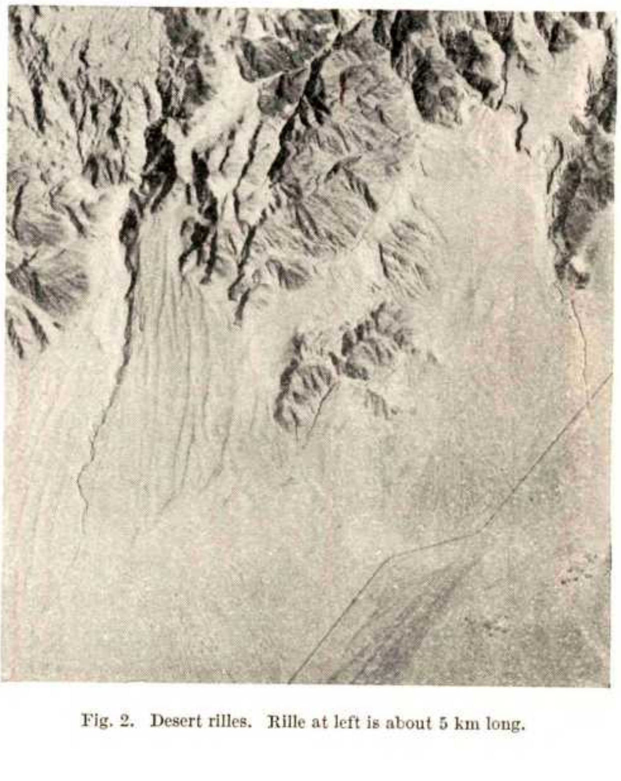

Fig. 2. Desert rilles. Rille at left is about 5 km long.

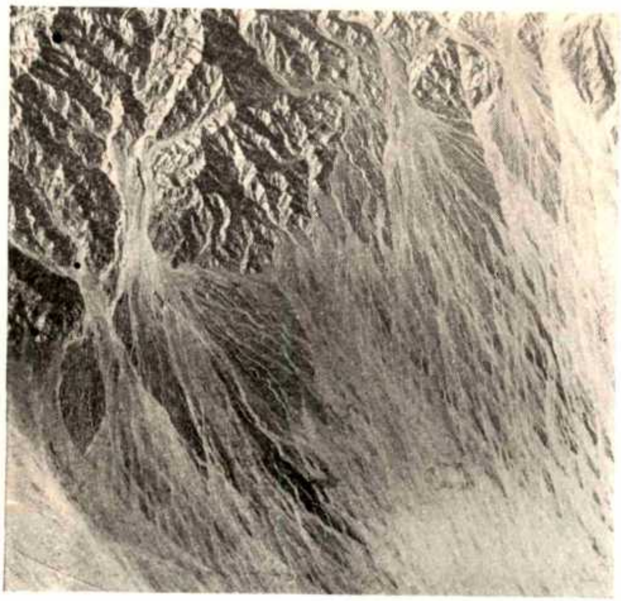

Fig. 3. Typical desert stream patterns on alluvial fans.

solidated, but usually these banks are hidden by windblown sand.

The highlands are the chief catchment area for runoff water and are massive granitic rocks made up of quartz, potassic feldspar and plagioclase. Some samples contain considerable biotite and/or horneblende, desert varnish and brown iron staining are common, and the average composition and texture are of quartz monzonite. The rilles are cut into old alluvial fans perhaps 150 m thick and composed of moderately sorted cobbles and pebbles in coarse arkosic sand. There are cross-bedded lenses, sections of micaceous siltstone, and cobble-boulder deposits. Windblown sand forms a veneer over the older alluvium and in some places has drifted into 10 m thick dunes. The sand consists of loose, fine-grained quartz showing frosting and rounding of individual grains from wind action. Silt and clay particles have been deflated from this material.

The site has been affected by several erosion cycles brought about by either climatic changes or changes in local base level. The oldest cycle affecting the rilles was of erosion that prepared the area for deposition of the older alluvium, which rests unconformably on the igneous rocks. The most recent cycles have again been erosion in which the older alluvium was cut. There are at least two terrace levels along the stream channels and one of these seems to have had a channel about five times the present width of the stream bed. The meander belt of the present stream is usually contained within the terrace scar of this older stream bed.

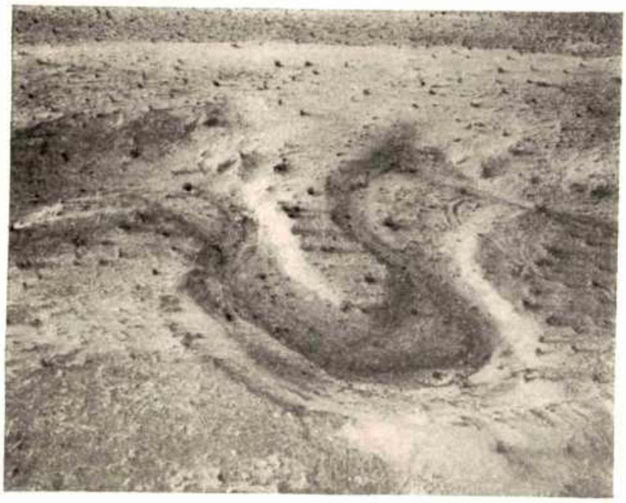

Fig. 4. Meanders in desert rille. Vehicle tracks give scale.

There are no indications of possible tilting or faulting of the older alluvium, but regional structure suggests that the western flanks of the igneous highlands are faulted. This igneous block forms a horst with a graben centred to the west in Deadman Lake. The older alluvium was built as a fan between the uplifted fault block and the Deadman playa, and drainage of the streams is dictated by this slope.

In the highland area the streams have typically youthful channels, but in the alluvium they are more mature. Because of the permeability of the older alluvium, the streams are more mature and incised near their origin than near their terminus. We tried to detect a subdued delta by examining the downstream ends of the desert rilles at low Sun angles. Some of the aerial photographs show what might be interpreted as accumulations of debris from the eroded stream channels, but ground observation suggests that most of the volume of material that should be present has been redistributed over a larger area by the combined action of wind and the wandering of the stream channels. The former courses are now hidden by the drifting sands.

Lunar rilles such as those trending down the flanks of the elevated area around Aristarchus resemble the California desert rilles in the following ways: (1) single sinuous channel, growing smaller from top end to lower end; (2) small inner channel meandering between terraces in a larger valley; (3) no braided channels, tributaries or deltas; (4) tendency to detour around obstacles and to parallel adjacent headlands; (5) cross-sectional profiles which are softly rounded with signs of slumping and soil creep features; (6) occasional subdued outcrops, with loose rocks on slopes and bottom of valley.

There are several differences, however. Lunar rilles tend to start in circular pits. In the desert this is simulated by the abrupt change from rock to sandy alluvium at the exit of the mountain canyon. Lunar rille slopes have a "tree bark" appearance which is probably a soil creep feature peculiar to the lunar environment. The desert rilles have a gradient of at least 30 m per km, and the gradient of the lunar rilles[5] is probably lower than this in most cases. The lunar rilles extend to much larger sizes.

We conclude that the difference between desert rilles and "normal" stream beds on the alluvial slopes has to do with the presence or absence, respectively, of a blanket of windblown sand. The desert rilles have ordinary water-cut channel banks of bedded alluvium near their upper ends, but these are often hidden by the windblown sand. It seems that the relationship between slope and transport capacity for the medium flowing in the rilles on both the Earth and Moon is such as to cause meandering, even to the point of incipient oxbow cutoff (see Figs. 1 and 4). On both Earth and Moon the presence of terraces is strong evidence for a change in either the base level or the supply of fluid at different times in the past.

We have two more speculative points. (1) The windblown sand may have had a primary and a secondary effect. The primary effect was to change the balance between erosion and transport for the stream, relative to what it would normally be at the point of emergence onto the alluvial pediment. The secondary effect was the softening of most channel topography by deposits of windblown sand (on the Moon, the mechanism was different presumably, meteorite redistribution or soil creep for example, but the result is similar). (2) As suggested by Lingenfelter *et al.*[6], the material in which the lunar rilles were eroded was unconsolidated during the flow, and may still be. It is not essential to postulate that a large quantity of lunar volatiles, such as ice, had to escape to account for the existence of a voluminous valley with no apparent delta. The volume of the desert rilles must be distributed at their downstream ends by the combined action of water and wind in such a way that all channels except the most recent are hidden. On the Moon, therefore, either the volume vanished by evaporation or there was a distribution mechanism which smoothed out the deposits as they were delivered at the downstream end.

We thank Colonel D. J. Burger, First Lieutenant Carlton Crenshaw and Gunner Sergeant R. E. Bingham, USMC, for their help, and Mr W. Sjogren of JPL, Dr George Ulrich of the US Geological Survey, and Mr R. Bryson of NASA for discussions. The aerial photographs were provided by the USGS and by G. Edwards and J. Gregoire of JPL. Sunrise and Moonrise at Stonehenge

A few years ago Hawkins[1-3] demonstrated that Stonehenge had more astronomical significance than previously recognized, but serious criticisms have been raised against parts of his theory. In particular, Atkinson[4,5] has challenged Hawkins's basic proposition that the Heel Stone indicated the direction of sunrise on midsummer morning. In this report I offer an improvement to Hawkins's theory, which accommodates this objection, and at the same time I propose an explanation of why the Heel Stone was asymmetrically situated, south of the centre line of the Avenue (see Fig. 1).

It is usually agreed[1,4,6] that when Stonehenge was in use an observer at its centre saw first light of the midsummer Sun somewhat to the left of the Heel Stone—in a direction indicated, at least approximately, by the axis of the structure and Avenue. Then the Sun rose upward and to the right; when directly above the Heel Stone, it hung just over the horizon, with its lower limb at an altitude of one-half degree.

Hawkins[1,3,7] argued that originally the Heel Stone extended one-half degree above the observer's apparent horizon, so midsummer sunrise was indicated by the Sun's standing tangent on the Heel Stone's tip; thus the Heel Stone fitted into the grand pattern of the astronomical theory, in which many other stones and archways similarly indicated most of the key rising and setting points of the Sun and Moon. Atkinson[4,5,7] argued that the Heel Stone never did extend above the apparent horizon, that the proper direction of midsummer sunrise was the direction of its first gleam, and that the Heel Stone's failure to mark midsummer sunrise cast significant doubt on Hawkins's entire theory. I wondered whether Hawkins and Atkinson might each be partly right.

If the Heel Stone and the axis had both designated the same celestial event, Stonehenge would have involved an unseemly redundance. I therefore sought another function for the Heel Stone and found that the Heel Stone accurately marked the rising point of the midwinter full Moon, if it happened to be precisely centred on the northern solstice point of the ecliptic. This direction of rising differed slightly from the direction of midsummer sunrise because of the geocentric parallax of the Moon, and it represented a set of rising points associated with the danger of a midwinter, lunar eclipse.

Some aspects of these ideas were originated by Hawkins, who explained[2,3] why the rising of the midwinter full Moon "over" the Heel Stone could have warned Stonehenge man of an impending eclipse. But considering Hawkins's concept of "moonrise" (lower limb tangent), his explanation involved another sizable error in altitude. Furthermore, Hawkins's reason for the off-axis location[1] of the Heel Stone had nothing to do with the Moon, and he continued to designate the Heel Stone as a sunrise marker[3]. I suggest that the Heel Stone was used exclusively as a winter eclipse moonrise marker, while the axis and Avenue were oriented toward midsummer sunrise. That would explain functionally why the Heel Stone was set slightly south of the centre line of the Avenue.

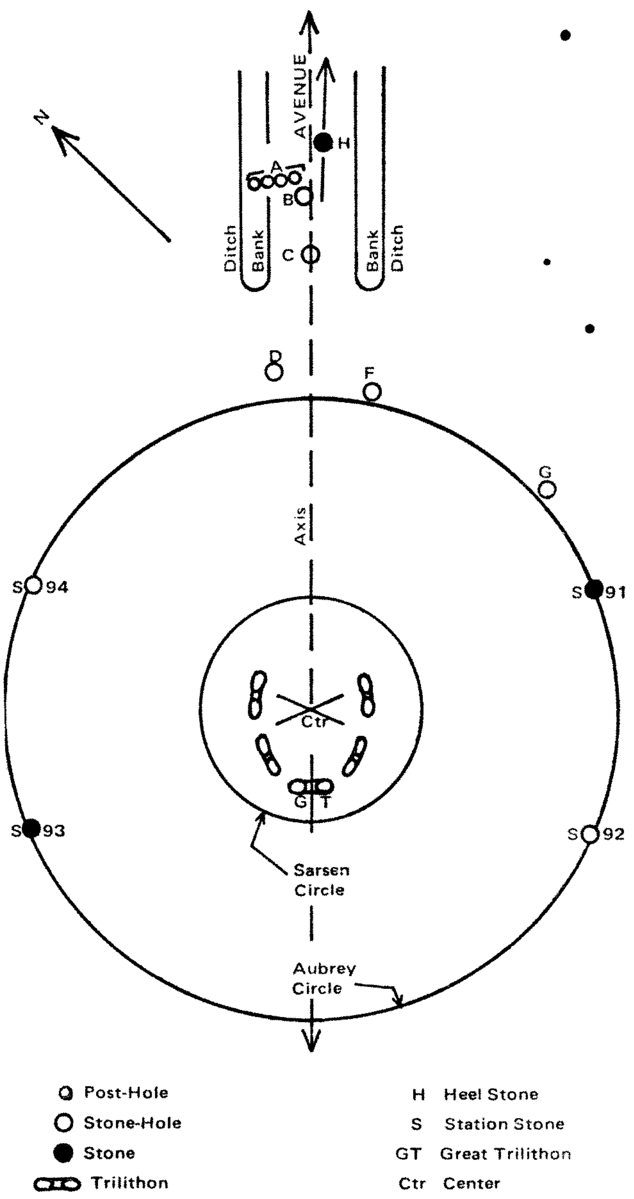

Fig. 1. Plan of Stonehenge.

The magnitude of the parallax effect provides a simple check that does not require any initial assumption about Stonehenge man's concept of "sunrise" and "moonrise". Celestial bodies rising beyond the Avenue and Heel Stone follow slanting paths, making an angle with the horizon of about 32°. Due to the Moon's proximity to the Earth, it has to rise 0·95° higher than the Sun does before it becomes visible on the apparent horizon (because the Moon's parallax is 0·95°, and the Sun's parallax is practically negligible). In the process of rising this extra 0·95°, the Moon moves 1·5° to the right. Thus if there was a winter solstice moonrise marker as well as a summer solstice sunrise marker on the Avenue, their azimuths should have differed by 1·5°.

Actually, there are two prominent stone-holes in the Avenue near the Heel Stone; one of them—stone-hole C—is well centred between the Avenue banks, and could have been the site of a precise Avenue axis marker. Measurements on a map of Stonehenge (Fig. 8 in ref. 4) showed that the azimuth of stone-hole C differed from that of the Heel Stone by 1·5°, as expected.

As an initial step of a second test, I calculated the altitude of the Sun—to see if it was indeed just beginning to rise—when at the azimuth of stone-hole C on mid-summer mornings around 1700 BC. The result was that the upper limb was just barely above the apparent horizon, by 0° 4′ of arc.

The accuracy of this result may have been fortuitous because the azimuth of stone-hole C had to be determined from measurements on a map of uncertain accuracy, but another similar calculation showed that on midwinter evenings, when the setting Sun was at the azimuth indicated by the Great Trilithon, its upper limb was only 0° 2′ from the horizon.

Furthermore, it followed that if the Heel Stone similarly marked winter eclipse moonrise, then the Moon at northern solstice should have been showing its upper limb just over the north-east horizon when at the Heel Stone's azimuth. Calculation confirmed that prediction, with a discrepancy of only 0° 5′.

Some additional implications seem worth mentioning:

(1) Atkinson was right in judging that the Stonehenge people watched for first gleam or last gleam of the Sun and Moon. (This was the same conclusion that C. A. Newham[6] reached by a different method.)

(2) Hawkins was correct in asserting great astronomical significance of Stonehenge, including some capability for predicting eclipses.

(3) The Heel Stone and other markers indicated directions only; altitudes were observed with respect to the distant horizon.

(4) Perhaps the astronomical theory of Stonehenge could be further improved, by reduction of other alignment "errors", if some of the other stones and archways were associated with the Moon rather than the Sun.

But one new question is how the Stonehenge people knew where the Heel Stone should be placed in order to indicate potential eclipse of the midwinter full Moon.

I suggest that the Stonehenge people first noted the passage of the seasons, by placing markers to indicate rising and setting points of the Sun on midsummer and midwinter days. That would have been a natural and easy thing for them to do empirically. Later they discovered that if the midwinter full Moon rose a bit south of the midsummer sunrise marker, then a lunar eclipse was likely. But if the midwinter full Moon rose much to the north or much to the south of the summer sunrise marker, then it was never eclipsed. So they just observed the north and south limits of winter full moonrise, and placed the Heel Stone midway between those limits.

My subsequent calculations showed that the full Moon closest to midwinter could have risen as far north as azimuth 41·1° or as far south as 61·4°; and the mean of these values was within 0·1° of the actual azimuth of the Heel Stone. The north and south limits of winter full moonrise as actually observed from Stonehenge were probably at azimuths somewhat greater than 41·1° and less than 61·4°, because each theoretical limit required conditions that almost never occurred simultaneously. Nevertheless, the direction midway between observed limits should have led to accurate placement of the Heel Stone, due to small imperfections counteracting each other.

My calculations were based, whenever possible, on the data presented by Hawkins in ref. 3; and my equations were essentially the same as his. Yet my numerical results were somewhat different, for various reasons: use of the first-gleam concept of sunrise and moonrise; use of 5·00° for inclination of the orbit of the Moon during non-eclipse seasons (instead of the average value 5·15°); and modification of Hawkins's table of atmospheric refraction versus geometric altitude—to include the effect of observer's height above sea level, as well as the effect of winter cold and summer heat (±20° F).

Earthquakes and Explosions: Comment on Molnar *et al.*

It is incorrect of Molnar *et al.*[1] to say that the shape of the surface wave spectra for discriminating between earthquakes and explosions had been hypothesized but not tested.

The spectral differences were demonstrated some two years ago as a result of P. D. Marshall's work in the Seismological Research Group of AWRE at Blacknest. These early results had been widely discussed here among colleagues from the USA[2] and the USSR. I presented this work, together with A. Douglas's theoretical studies on the same problem, to the Seismic Study Group sponsored by SIPRI in Stockholm. Marshall's experimental data, which include those of explosions at the American, French and Russian test sites, are published in *Seismic Methods for Monitoring Underground Explosions* (SIPRI, Stockholm, 1968). So far as I know, they are the only teleseismic explosion versus earthquake surface wave spectra published to date.

Molnar's contribution to this problem vividly demonstrates the value of broadening the recording band for this purpose, provided this can be done without raising the detection threshold (m_b 4·5 explosions) which, if necessary, could be achieved by narrow band long period systems. They demonstrate that it is possible to eliminate environmental noise at the bottom of a deep mine, and thereby operate at magnifications which are comparable with a narrow band system.

The broader interests of seismologists have been well served by this painstaking instrumental development. In the more restricted field of detecting underground explosions, it remains to be seen whether a world-wide network of instruments in near-surface vaults will be capable of detecting surface waves of small distant explosions. On Molnar's evidence, the detection threshold for explosion generated surface waves for the Ogdensburg mine wide band system lies between m_b 5 and m_b 5·3 at a distance of 3,500 km.

Reply to Thirlaway

WE apologize to Thirlaway and his colleagues for stating categorically that the shape of the surface wave spectra for discriminating between earthquakes and explosions was suggested prior to our work[1] but not tested. The two figures presented by him in the SIPRI report[2] certainly suggest such spectral differences for explosions and earthquakes. For his data, however, it is not possible to attribute these differences unambiguously to the two kinds of sources because earthquake and explosion data were not shown for the same region. Because Liebermann and Pomeroy[3] and others demonstrate large regional differences in M_S–m_b populations, sceptics could question the interpretation of these differences. Also, the two figures are presented with practically no discussion; we strongly urge publication of the results through established journals. His explosion data do not extend to periods greater than 25 s for two events and about 33 s for the third.

Our explosion and earthquake data[1], however, were obtained for nearly identical source regions and propagation paths, and they extend to periods of about 50 s. Thus we can unambiguously state that differences in the source spectra for the set of explosions and earthquakes that we studied must be attributed largely to differences in the two different types of source time functions and not to differences in focal depth, propagation path, radiation pattern or source dimensions.

We agree that it remains to be seen whether instruments (particularly long period horizontal seismometers) in near-surface vaults will give results comparable with those obtained in the New Jersey mine. Nevertheless, we are optimistic that this can be done. Our location in an active zinc mine is, in fact, quite noisy for long period pressure fluctuations. We successfully eliminated pressure changes as a major contributor to the seismic background noise. Amplitudes of microseismic noise for periods near 20 s in the mine are comparable with those reported[2] for high-quality sites on the surface. Because our instruments are limited by microseismic noise with periods near 20 s, detection capability is not sacrificed by broadening the recording band in comparison with existing narrow band instruments peaked near 20 s.

We stated[1] that we did not have adequate data for m_b (USCGS) less than 5·0 to identify the lower threshold for detection and discrimination of explosions and earthquakes. Also, we noted that body-wave magnitude, m_b, as determined by the USCGS for events in western North America, tends to be larger than determinations made at great distance (which form the basis for most comparisons of detection and discrimination levels[2]). Thus Thirlaway's assessment of our detection threshold probably is a pessimistic interpretation of our results.

In our analysis, a comparison of 50 s Rayleigh waves with m_b seems to be the best discriminant for underground explosions and earthquakes. The amplitudes of 50 s waves for the smallest explosions detected (m_b 5·3) are about twenty times smaller than those for earthquakes of the same m_b. The near parallelism of the explosion and earthquake populations makes us optimistic that the discrimination threshold can be lowered by similar study of additional earthquakes and explosions with $4·0 < m_b < 5·0$ and by more sophisticated data processing.

Measurements on Cloud Chamber Tracks

RECENT work reported from Sydney[1-5], on tracks in cloud chamber photographs of particles near the axis of extensive air showers, might be interpreted in terms of particles of subunit charge. It is important, however, to examine the conditions in which normal tracks might possess the reported features. This report draws attention to some specific effects.

If the images counted in this work are indeed drops, data reported by Ghosh, Jones and Wilson[6], from a study of the logarithmic rise of ionization with increasing energy for muons, are relevant. These include two distributions of actual measurements for segments, of 1 cm and about 15 cm respectively, of drops from field-separated tracks near the minimum of ionization in the fully condensed positive ion column. They refer to oxygen at standard pressure and exclude ion clusters arising from energy transfers of about 1 keV upwards. The actual number of drops condensed on the ions of an unseparated plateau track in the Sydney work probably lies in the range 100–160 drops per centimetre, according to the completeness of condensation and the criterion adopted for the exclusion of large energy transfers (delta-rays). Accordingly, this implies that, if condensation were complete, the reported drop counts refer to those in about 1·5 cm of track and the fluctuations would be comparable with those in about two centimetres of the tracks measured by Ghosh *et al*. These fluctuations would therefore be more like those of Fig. 2 than of Fig. 3 of that paper. If condensation were incomplete, the counts would refer to a greater length of track, but an additional fluctuation, caused by actual condensation taking place would be introduced. In either case, the extreme fluctuations would certainly be large and the reported measurements would fall near to them.

Fluctuations of numbers of single drops, although these must occur, are most unlikely to represent the whole situation correctly. The workers in Sydney have sent me direct contact prints of their negatives (from and onto 35 mm film), and it seems that the number of objects counted per centimetre of track is of the order of 30–40 and certainly nothing like 100–160. The Sydney tracks are said to be about 0·17 cm wide, and the magnification for the plane of the tracks is likely to be about 1/13. The smallest objects counted were about 20 μm in diameter, and objects larger than this may be irregular. They do not cover more than about one-fifth of the whole track area. The most likely interpretation is that detectable objects in the track are derived from superpositions of drop images, and that in these photographic conditions the image of a single isolated drop does not produce a recognizable blackening of the emulsion. This statement is probably not correct for all the Sydney photographs nor necessarily for the whole area of some others, but it does seem to apply in the region of the particular photograph used by McCusker and Cairns[1].

The nature of superposition involved in the formation of these objects can be deduced from the fact that they are not concentrated exclusively along the central line of the track. Indeed, their spread from this line forms the basis for measuring the track breadth. The significance of this feature is apparent from Plates I and II of Ghosh *et al.*[6]. The middle point of the image of an energetic delta-ray may be displaced from the central line of the track (Plate II), but those of smaller drop clusters (Plate I) are not. Superpositions which do not lie on the central line are not usually caused by the drops having a common origin in still smaller clusters. While primary ionization will have been spaced on average about 0·03 cm along the line of track, the distance of "random walk", along which many ions must have moved to reach the points where they contribute to an image, must have been several times greater than this value. Accordingly, the drops can be considered to be independent in origin. This suggestion about what is in fact photographed should lead to tracks rather less diffused than those expected from the reported time delay of photography, because the ions which diffused furthest would reach relative isolation and would probably be unrecorded. This effect should be examined in detail from the primary data, acceptance criteria and techniques. But a rough indication, using reasonable figures, is worthwhile.

One centimetre of track is 0·17 cm² in area and gives an image area of about $1 \cdot 0 \times 10^{-3}$ cm². Suppose the effective size of a single drop image is comparable with that of the smallest visible objects in the pictures (4×10^{-6} cm², or 4×10^{-3} of the area of the image of 1 cm of track) and that effective overlapping leads to a visible object in the photograph if the centre of one drop image falls anywhere within the 4×10^{-6} cm² area of another image. A rough calculation indicates that for a track density of 150 drops/cm, there will then be seventy-nine non-overlapping drops, twenty-five pairs of overlapping drops and seven examples of multiple (three or greater) superposition. Thirty-two objects will therefore be visible if the images of isolated drops are not seen and 111 objects if the images of single drops are visible. For a track density of 100 drops per centimetre, the corresponding numbers of objects in the image are sixteen and eighty-two respectively. These figures, although derived from a very rough analysis, are comparable and the change from 100 drops/cm to 150 drops/cm, a ratio of 1·5, is similar to the difference between the minimum of ionization and the relativistic plateau.

If all drops and drop overlaps were recorded, the observed ratio would not be 1·5, but 1·35, and there would also be about 110 objects/cm in the measured plateau track. If only superpositions yielded recordable objects in the photograph, the corresponding ratio would be 2·0 and there would be about thirty objects per centimetre. These ratios, so strikingly different, even before any consideration of fluctuation has been introduced, emphasize the need for an exact analysis based explicitly on the Sydney work and the material used in it.

This discussion has been concerned with features which do not seem to exclude the possibility of the tracks being normal. The most difficult characteristic of the published data to relate to normal tracks, however, is the relative lack of delta-rays. This should not be sensitive to the nature and energy of the initiating particle but should depend strongly on its charge. There is therefore a good chance that selection could be made of delta-rays which would apply in different parts of a single photograph and for many photographs. It is true that the relatively small number of delta-rays make large fluctuations on a limited length of track probable, but sufficient delta-ray counts might be made to establish whether or not the number counted on tracks such as that published[1] can possibly lie in the tail of a general distribution.

Frequency Mixing in the Scattering of Light by Harmonically Bound Electrons

Classical electrodynamics predicts harmonic generation[1-3] and frequency mixing[4] in the scattering of light by free electrons. Quantum theory confirms these results[3-7]. Several authors (for example, refs. 8 and 9) have used the classical anharmonic oscillator model to give a qualitative account of non-linear phenomena in dielectrics. In the absence of an anharmonic restoring force, non-linear effects, up to the lowest order in external electric field, are in general quite small[10]. Calculations[11] stress this point in the case of second harmonic generation in the scattering of light. Here we extend these calculations to study the scattering of light when the incident beam contains two frequencies. As expected, we find that the combination frequencies also exist in the scattered radiation besides the fundamentals and their harmonics, and that the non-linear cross-sections become large for resonant denominators. Further, a proper choice of the two incident frequencies can yield an appreciable increase in the non-linear scattering cross-sections even without any precise resonance.

The equation of motion of the electron bound by a restoring force $m\omega_0^2\,\mathbf{z}$ when the incident electromagnetic beam contains two frequencies ω_a with wave vectors K_a $(a=1,\,2)$ can be written as

$$v_0[\ddot{\mathbf{z}}+v^2\,(\ddot{\mathbf{z}}\cdot\dot{\mathbf{z}})\,\dot{\mathbf{z}}]+\omega_0^2\mathbf{z} = (e/m)\sum_a\{\mathbf{E}_a+[\dot{\mathbf{z}},\,\mathbf{H}_a]\}\cos\,(\omega_a t-\mathbf{k}_a\cdot\mathbf{z}+\delta_a) \qquad (1)$$

where $\mathbf{z}$ is the position of the electron, δ_a are constants and $v_0=(1-\dot{\mathbf{z}}^2)^{-1/2}$.

This equation can be solved by making a perturbation expansion in power of E_a $(|\mathbf{E}_a|=|\mathbf{H}_a|=E_a)$. The radiation field can then be evaluated by a method described in detail in ref. 1. It contains a complete spectrum of combination frequencies as well as the fundamentals and their harmonics. If terms are retained up to the third order in the amplitude of the two incident frequencies, scattering cross-sections are produced which correspond to sum and beat frequencies, along with those for fundamentals and their harmonics. Explicit expressions for the total cross-sections for scattering into ω_1, $2\omega_1$ and $\omega_1+\omega_2$ are given by

$$\begin{aligned}\sigma\omega_1 = {} & (I_1/I_0)\sigma_T\omega_1{}^4\,g_1{}^2\,[1+(1/20)\,q_1{}^2\,g_1\,\omega_1{}^4\,(10\,g_{1+1}-g_1+ \\ & 15\omega_1{}^2\,g_1{}^2)+(1/40)\,q_2{}^2\,\omega_2{}^2\,\{10\omega_1{}^2\,g_1\,(g_{1+2}+g_{1-2})+ \\ & 10\omega_1\omega_2\,g_2\,(g_{1+2}-g_{1-2})-\omega_1{}^2\,g_2{}^2+30\,\omega_1{}^2\,\omega_2{}^2\,g_1\,g_2{}^2\}]\end{aligned} \qquad (2a)$$

$$\sigma_2\omega_1=(32\pi e^2/5m^2)\,(I_1{}^2/I_0)\,\sigma_T\,\omega_1{}^6\,g_1{}^2\,(5g_{1+1}{}^2+g_1{}^2) \qquad (2b)$$

$$\begin{aligned}\sigma\omega_1+\omega_2 = {} & (2\pi e^2/5m^2)\,(I_1I_2/I_0)\sigma_T(\omega_1+\omega_2)^4 \\ & \times[5(\omega_1\,g_1+\omega_2\,g_2)^2\,g_{1+2}{}^2+(\omega_1+\omega_2)^2\,g_1{}^2\,g_2{}^2]\end{aligned} \qquad (2c)$$

where

$$g_{a\pm b}=(\omega_0{}^2-\omega^2{}_{a\pm b})^{-1}, \quad q_a=e\,E_a/m\,\omega_a,$$

$\sigma_T=(8\pi/3)_{r_0}{}^2$ is the Thomson scattering cross-section, $I_a=E_a{}^2/8\pi$ is the intensity of the components of the incident wave, and $I_0=I_1+I_2$.

Total cross-sections for scattering into ω_2, $2\omega_2$ and $\omega_1-\omega_2$ can be obtained from those for ω_1, $2\omega_1$ and $\omega_1+\omega_2$ respectively by interchanging the suffixes 1 and 2 in the first two cases and changing the sign of ω_2 in the third. In evaluating cross-sections for the fundamental frequency we have excluded the case $\omega_1=\omega_2$, for its inclusion would unnecessarily complicate the calculations.

We may note that the expressions for $\sigma\omega_1\pm\omega_2$ obtained here agree in the limit $\omega_0/\omega_a\rightarrow 0$ with those given by Fried and Frank[7] and do not agree with those given by Prakash and Vachaspati[4]. Expression 2*c*, however, is consistent with 2*b*, as can be seen by putting $\omega_1=\omega_2$.

Expression 2*b* is in general quite small, except for resonant denominators (see equation 7*d* of ref. 11). The same is true for 2*c*, and for the intensity dependent part of expression 2*a*. It may, however, be noted that the cross-section for the fundamental frequency, ω_1, depends not only on ω_1 but also on ω_2. The change in the cross-section of the fundamental frequency due to the presence of ω_2 is easily obtained from the expression under the curly bracket in 2*a*. It is determined by the relative positions of ω_1, ω_2 and ω_0 in addition to the intensity of ω_2. Simple numerical analysis shows that this change is too small to be detectable when neither ω_1 nor ω_2 $(\sim\omega_1)$ is in resonance with ω_0. When $\omega_1\gg\omega_2$, ω_0 an interesting situation arises. It is clear that the cross-section for sum and difference frequencies should in this case be added to that of the fundamental. The total increase in $\sigma\omega_1$, denoted by $\Delta\sigma\omega_1$, can then be seen to be $\sim(3\pi/5)\,(e^2/m^2c^3)I_2\,\sigma_T\,\omega_1{}^2\,g_2{}^2\sim 1{\cdot}4\times 10^{-3}\times(\lambda_2{}^3/\lambda_1 d)^2 I_2\,\sigma_T$, $\lambda=2\pi c/\omega$, if ω_0 and ω_2 are of the same order and $d(=\lambda_0\sim\lambda_2)$ is expressed in Å. It can further be seen that $\Delta\sigma\omega_1$ is larger than $\sigma_2\omega_1$ or $\sigma\omega_{1\pm}\omega_2$ $(\omega_1\sim\omega_2)$ for a large d.

The expression for $\Delta\sigma\omega_1$ given above suggests that the non-linear increase in scattering could become large. This could happen also for those incident frequencies that are far away from the resonance frequency of the scattering body which consists of harmonically bound electrons. As an illustration we consider a simple experiment consisting of the scattering of two incident light beams, one of which is ruby laser light ($\lambda_2\sim 7\times 10^{-5}$ cm, $I_2\sim 10^7$ W/cm², say), by sodium vapour ($\lambda_0\sim 6\times 10^{-5}$ cm, $d\sim 10^3$ Å). For this case we find the non-linear increase in scattering to be $\Delta\sigma\omega_1\sim 1{\cdot}7\times 10^{-20}\times\lambda_1{}^{-2}\,\sigma_T$, which is appreciable for high frequencies and seems to be experimentally detectable for λ_1 in the X-ray region. Instead of sodium vapour as scatterer and ruby laser light as one of the incident beams, one can choose other scatterers and incident frequencies. With the advent of dye lasers one can have a fairly intense coherent radiation over a wide range of frequencies. This would allow for a suitable selection of λ_2, and hence of d, for a given λ_0, keeping in view the availability of I_2 and λ_1.

We thank Professor E. H. Hutten for his interest in this work, and the Royal Holloway College and the Science Research Council for their financial support.

Measurements of Electrical Potential for detecting Crack Extension in COD Tests

THE crack opening displacement (COD) test is currently being used by a large number of research establishments throughout Britain and the USA to establish the fracture characteristics of high toughness–low strength steels.

When a pre-cracked fracture-toughness specimen breaks in a rising load test, the crack tip opening displacement at fracture is frequently deduced from displacement measurements made on the surface of the specimen using a clip gauge. If the specimen size is such that fracture occurs under plane stress or mixed plane stress–plane strain conditions, final rupture may be preceded by a period of stable crack growth. Slow growth may be an essential prelude to fast fracture, so the COD at which it starts can in one sense be regarded as a critical value. Unfortunately, this information cannot be deduced from the conventional force-displacement record of a fracture-toughness test because COD and crack growth affect the surface displacement similarly. This type of behaviour is retarding the development of the COD test, but we believe that we have successfully circumvented this obstacle to the use of the COD measurements for fracture toughness assessment by using the potential drop method of measuring cracks developed by Gilbey and Pearson for fatigue work[1].

Tests were conducted on full-plate-thickness mild steel specimens (256 MNm⁻² 0·2 per cent proof stress at 10° C) of the following composition: 0·2 per cent carbon, 0·05 per cent silicon, 0·03 per cent sulphur, 0·01 per cent phosphorus, 0·69 per cent manganese.

The specimens of the single-edge-notched configuration were tested in three-point-bending. Their dimensions

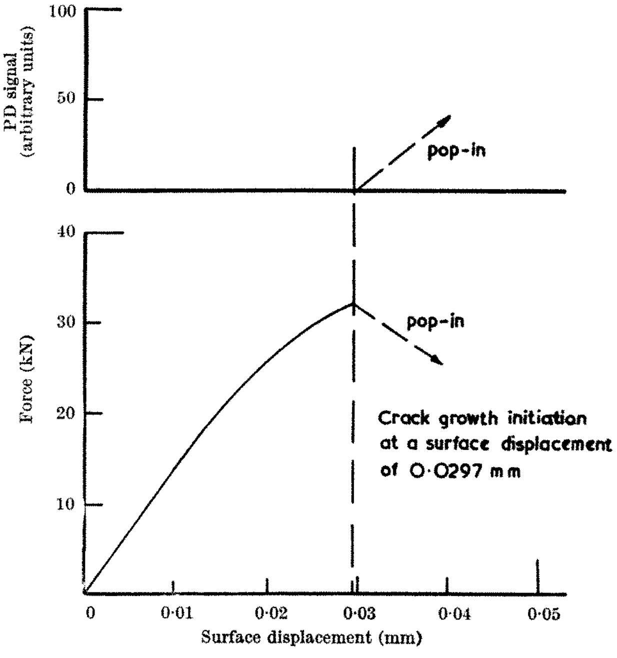

Fig. 1. Type 1 test record indicating an absence of slow crack growth before pop-in.

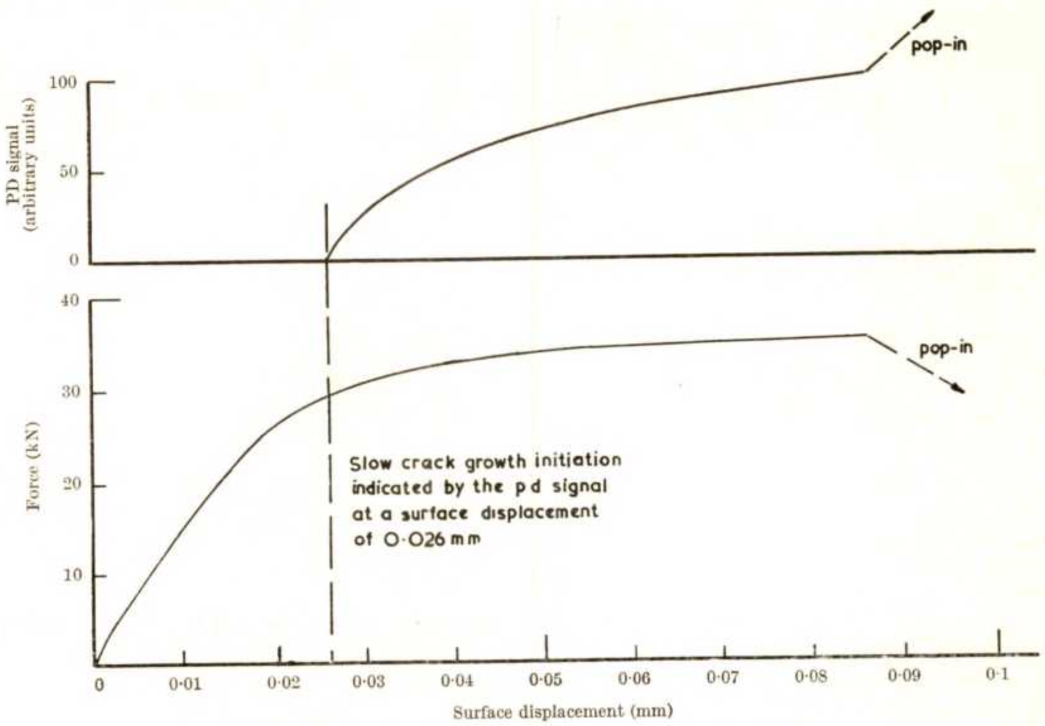

Fig. 2. Type 2 test record indicating slow crack growth before pop-in.

(American Society for Testing and Materials notation) were $B = 28$ mm, $W = 62$ mm, $a = 31$ mm. The tests were conducted in accordance with the proposed British Standard for fracture toughness testing, surface displacement[2], measured using a clip gauge being autographically recorded as a function of the force applied to the specimen. In addition, nichrome wire probes of 0·2 mm diameter were capacitor-discharge-welded to the specimen at points 6·2 mm (0·1 W) on either side of the centre-line of the notch at a distance 15·5 mm (0·25 W) from the notched face of the specimen. A constant direct current of 10 A was passed through the specimen, being introduced at points remote from the notch. Crack extension was detected by monitoring the potential difference between the nichrome probes, this being a "function" of crack length in constant current conditions. The probe signal, after amplification, was recorded on an ultraviolet recorder together with the load cell signal.

In tests conducted at 10° C, two types of behaviour were observed. In the first type of test (Fig. 1) the probe signal, replotted here as a function of surface displacement, did not increase before pop-in. The specimen's fracture face was later examined using a Stereoscan scanning electron microscope and this confirmed that no ductile tearing preceded brittle fracture (Fig. 3*a*). In the second type of test (Fig. 2) the probe potential rose before pop-in, indicating that stable crack growth was occurring. This was subsequently confirmed by Stereoscan observations (Fig. 3*b*).

Concerning the test records, it may well be significant that both brittle fracture and slow crack growth appear to have initiated at similar CODs in these specimens. At this stage, however, comments will be restricted to the potential drop technique itself. It provides a simple yet sensitive method for detecting crack extension and moreover might be made quantitative by previous calibration of the specimen.

Experimentally, application of the method presents few problems, but the following points should be noted. In the vicinity of the crack tip the measured potential is very sensitive to the position of the probes. It is therefore inadvisable to place them in this region because the slight displacement associated with the opening of the crack will affect the signal. They are best positioned on the notched face of the specimen if this is compatible with the clip gauge mounting. In this position the probe signal is unaffected by COD but remains adequately sensitive to crack extension. Second, a small thermo-electric e.m.f. may be superimposed on the probe signal. For qualitative work this is not important provided that it remains constant. Ideally the thermo-electric e.m.f. should be eliminated by using probes of the same material as the specimen. Alternatively the basic potential signal can be

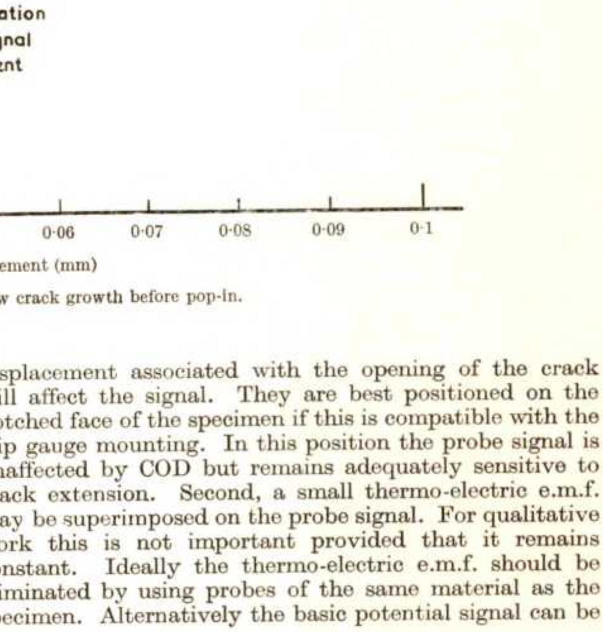

Fig. 3. Scanning electron fractographs showing (*a*) the absence of ductile tearing associated with type 1 behaviour and (*b*) the ductile tearing associated with type 2 behaviour. X, Fatigue area; Y, ductile tearing; Z, brittle fracture (× 187).

increased (by increasing the current) so that the thermal contribution is negligible.

The method is less suitable for use on very large specimens, first because the size of the constant current source required becomes excessive and second because the change in potential is dependent on the change in (a/W) and hence becomes less sensitive to absolute crack extension as W increases.

We believe that additional instrumentation of this or a similar nature is essential if progress is to be made in the development of the COD approach to fracture toughness assessment. It must be accepted that as general yielding is approached in the regime of mixed mode or plane-stress failure, the simple instrumentation used for plane-strain fracture toughness testing is no longer adequate.

We thank Dr G. S. Lane, BR Engineering Research Division, for performing the fractographic work.

Occurrence of Indium in Seawater and some Marine Sediments

LITTLE is known about the occurrence of indium in the marine environment. Shaw[1] succeeded in detecting it at concentrations between 0·06 and 0·28 p.p.m. in four of the eleven marine sediments that he examined. No figures seem to have been published yet for the occurrence of the element in seawater, although Baric and Branica[2] have deduced from polarographic studies of saturated solutions of indium in seawater medium that its concentration should be 10^{-10} M. We have determined indium at four depths in the water column at Discovery Station 6917 (23° 00′ N, 18° 42′ W, depth 3,100 m). 'Millipore' filtration (0·45 μm) and preliminary concentration of the indium (by means of chelating ion exchange[3]) were carried out at sea immediately after the samples had been collected. The recovered indium was purified by anion exchange using 'Dowex *AG*2-X8' and then irradiated with thermal neutrons at a flux of 5×10^{12} neutrons cm^{-2} s^{-1} for four weeks. The irradiated sample was taken up in concentrated hydrochloric acid, equilibrated with 15 mg of inert indium as carrier and submitted to a twelve stage radiochemical separation to free the ^{114}In from other radioactive species. Indium was converted to its oxinate for determination of the chemical yield (~60 per cent) and for β-counting. The identity of the separated ^{114}In activity was confirmed by measurement of the half-life, plotting an aluminium absorption curve, and by γ-spectrometry. The concentrations of indium found at depths of 2, 500, 1,000 and 2,000 m were 0·31 ± 0·02, 0·12 ± 0·01, 0·10 ± 0·01 and 0·11 ± 0·01 ng/l. respectively. These concentrations are of the order of a hundred times less than those predicted by Baric and Branica[2]. Neutron activation analysis was also used to determine indium in three deep sea sediments (Table 1). The concentration of indium found in the argillaceous sediment is identical with that found by Shaw[1] in a red clay from the Equatorial Pacific. He was, however, unable to detect indium in a siliceous ooze or in a calcareous ooze.

Late Maastrichtian Nannoplankton Provinces

IT has been known for some time that there was a sharp differentiation of late Maastrichtian faunal provinces with respect to planktonic foraminifera. Axelrod[1] has presented evidence that this was also the case with some terrestrial megaphyta, for he found a rather abrupt southward shift for the coniferous vegetation of the northern hemisphere during this time. Before this provincialism was discovered, serious problems were encountered in long-range correlation by planktonic foraminifera, because the two late Maastrichtian species, *Abathomphalus mayaroensis* and *Racemiguembelina fructicosa*, are both restricted to the tropics (Fig. 1: *A. mayaroensis* is extremely rare in the two northernmost occurrences (Denmark and Sweden) shown).

Associated with the planktonic foraminifera in marine sediments are skeletal remains of minute planktonic calcareous algae, usually referred to as the calcareous nannoplankton, which are used for age determination of the sediments—especially in small deep sea samples—and on which a detailed zonation is based.

It was at first thought that late Maastrichtian nannofossils were more cosmopolitan than the foraminifera and could eventually be used for correlation in areas

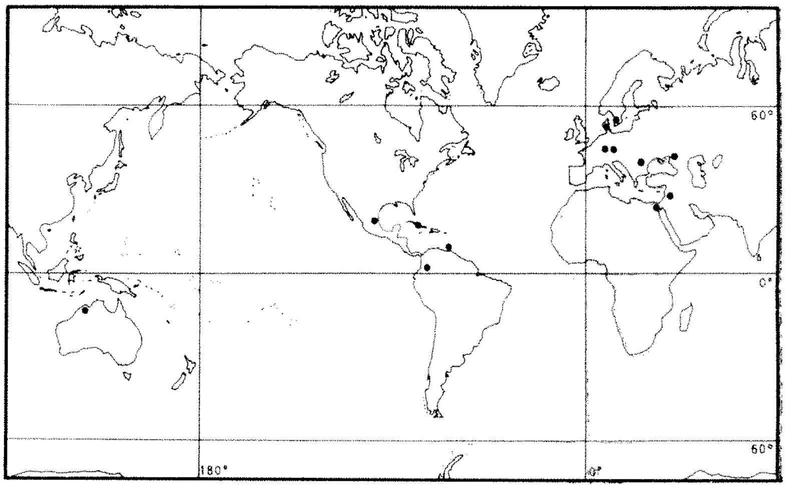

Fig. 1. Occurrences of *Abathomphalus mayaroensis* and/or *Racemiguembelina fructicosa* in the Upper Maastrichtian.

where the planktonic foraminifera were faunally restricted, but evidence has come to light that this is not entirely the case. It seems now that two of the latest Maastrichtian nannofossil index species, *Tetralithus murus* and *Nephrolithus frequens* (that is, *N. frequens* Gorka and closely related forms), were climatically restricted. Fortunately, *N. frequens* occurs toward the poles while *T. murus* is tropical, unlike their foraminiferal counterparts *A. mayaroensis* and *R. fructicosa*, both of which are tropical. It can be seen from Table 1 that *T. murus* and *N. frequens* have been found to occur together only in south-west France[2]. The occurrence of the diagnostic late Maastrichtian planktonic foraminifer *A. mayaroensis* and the belemnite *Belemnella casimirovensis* is also plotted on this table for comparative purposes.

It is highly significant that while *T. murus* is always restricted to the latest Maastrichtian, *N. frequens* is a latest Maastrichtian guide fossil only towards the limits of its province[2]. In south-west France, where both are found together, their known stratigraphic range is approximately ten metres. In the United States, the two have not been found together but have been reported from within a few hundred miles of each other. In Alabama, *N. frequens* is restricted to the uppermost two metres of the Maastrichtian. It is absent in Texas and Arkansas, but *T. murus* has been identified from a single sample from Arkansas[2]. This distribution pattern fits remarkably well with that of the planktonic foraminifera. *A. mayaroensis* has not been found in the Gulf Coastal Plain north of the Tampico Embayment in Mexico, and *R. fructicosa* has been reported from Texas but no farther east, according to Čepek *et al.*[14]. Fig. 2 shows the distribution of occurrences of *T. murus* and *N. frequens* along with the known thickness of the sequence in which they occur for each locality. It is evident that the stratigraphic ranges of both these species seem to be a function of latitude, with *T. murus* thinning toward the poles and *N. frequens* thinning toward the equator.

If *N. frequens* and *T. murus* are indeed provincial, it becomes possible to predict where the most likely additional occurrences of each are likely to be found. *N. frequens*, to our knowledge, has been reported from all the known high-latitude calcareous Upper Maastrichtian sections. It seems probable, however, that a careful search of the Upper Maastrichtian strata containing *A. mayaroensis* and/or *R. fructicosa* might yield *T. murus*. Especially promising areas for search are the Tampico Embayment and western Texas.

As more pelagic sediments of Maastrichtian age are recovered, we cannot refrain from speculating that neither *N. frequens* nor *T. murus* will be found in them because of a rapid upward migration of compensation level in the deep sea during the late Maastrichtian as worldwide climates changed. Should either ever be found, however, one could predict that it would be *T. murus* because it will have been deposited nearer to the late Maastrichtian equator where the compensation depth was probably closer to the bottom in the deep ocean basins, as shown by present conditions[16], and where increased productivity overbalanced the increased rate of solution of calcium carbonate[17].

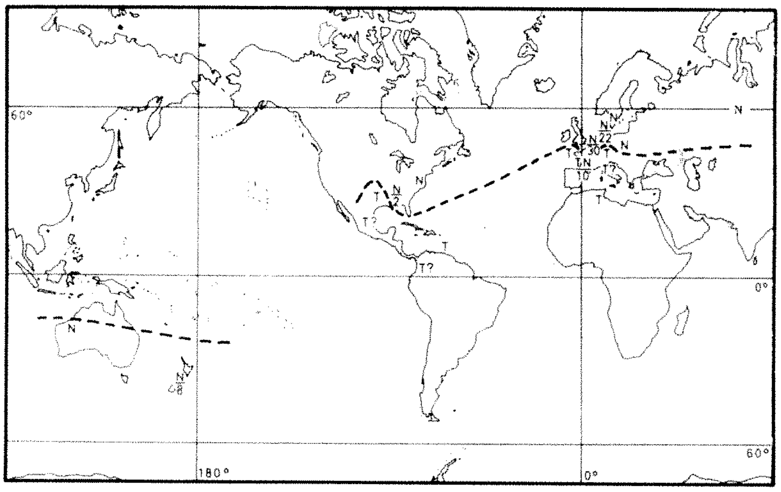

Fig. 2. Late Maastrichtian nannoplankton provinces (**N**, ***Nephrolithus frequens*** **and closely related species**; T, ***Tetralithus murus***; T ?, suggested occurrence of *T. murus*; numbers, if shown, indicate minimum thickness in metres of strata in which one or both species occur).

BIOLOGICAL SCIENCES

Derivation of Partial Sequence of Human β Chain Messenger RNA from Mutation Data

THREE general approaches can be used to determine the base sequence of natural messenger ribonucleic acids (mRNAs): (1) the molecular species in question can be purified and sequenced by chemical methods[1]; (2) purified aminoacyl-tRNAs (which are codon-specific) can be used to deliver labelled amino-acids to particular sites in a protein of known sequence[2,3]; and (3) the mRNA sequence can be inferred from the pattern of amino-acid substitutions in mutant proteins of known sequence[4-6]. It has been possible to determine indirectly the RNA sequence which codes for a carboxy-terminal segment of lysozyme[4], but no intensive effort seems to have been made to apply the large amount of sequence data[7] accumulated on homologous proteins to similar ends.

If the universality of the genetic code is assumed[8], examination of amino-acid substitutions in a series of proteins shown to have a common ancestral origin should reduce considerably and sometimes uniquely specify the probable codons for certain amino-acids. These data could be of great assistance to those determining the sequences of mRNAs directly and might provide information on codon frequencies not easily obtainable by any other method.

Because the mRNA for the β chain of haemoglobin has been considerably purified[9] and the nucleotide sequence may soon be known, that protein was chosen for study. Realizing that in most cases distinction could not be made between "wobble" codons[10], fifty-eight human β chain variants[9] and the amino-acid sequences from β chains of thirty-six animal species[7] were compared with the normal human β chain and the codons compatible with each amino-acid deduced. For example, residue 67, which is normally occupied by valine in human β chains, is known to have mutated to glutamic acid in human haemoglobin M Milwaukee, and is occupied by isoleucine in lamprey globin. If it is assumed that the minimum number of base changes should be invoked to explain each difference in amino-acid sequence, then the observations are most compatible with an assignment of the GUA codon to residue 67 in the human β chain. When multiple amino-acid substitutions involving a single codon were not compatible with single base changes, it was still sometimes possible to arrive at a unique sequence of base changes, involving a minimum number of steps, which would both explain the observed amino-acid interchanges and be compatible with accepted phylogenetic relationships[7].

By this method it was possible to derive probable codons for seventy-two of the hundred and forty-six amino-acid residues in the human β chain (Table 1). All three bases of the triplet could be specified for ten of these residues: valines 1, 113, 126, 98 (GUG), valines 54 and 67 (GUA), leucines 31 and 48 (UUG), glycine 29 (GGA) and alanine 62 (GCG). For the remaining sixty-two residues on which sufficient substitution data are available to restrict significantly the possible codon assignments, only the first and second elements of each codon triplet could be specified with certainty although some possible codons could be eliminated. In no case was support for mRNA heterogeneity in the human encountered, that is, no data required that multiple codons for a single amino-acid residue be postulated.

Besides limiting the possible codons at many positions, significant features of the coding for arginine and the amino-terminal valine are revealed. For all of the arginine residues in the β chain, the AGA–AGG codon set was unequivocally specified by the mutation pattern. This observation is consistent with nearest neighbour studies which suggest that C–G sequences are relatively rare in DNA[12]. Although inconclusive, results of incorporation of labelled amino-acids by fractionated arginyl-tRNA into rabbit β chains are consistent[3] with this conclusion. On the other hand, the CGN set of codons (where N specifies A, U, G or C) is used for arginines 92 and 141 in the α chain[3] of rabbit haemoglobin and these codons are almost certainly used in man as well[9]. There therefore exists the possibility of differential control of α and β chain synthesis by regulation of the availability of tRNA species which recognize the CGN set. Selective reduction of α chain synthesis by tRNA restriction has been demonstrated *in vitro*[13] and may be relevant to the mechanism of α thalassaemia in which α chains are structurally normal but their rate of synthesis is reduced.

Table 1. TRIPLETS FOR SOME AMINO-ACIDS IN HUMAN HAEMOGLOBIN β CHAIN

Amino-acid	Position	Possible codons
Alanine	62	GCG
	13, 128, 140	GCC, GCU
	142, 10 53, 70, 76, 86, 135, 138	GCA, GCG
	27	GCA, GCC, GCU
Arginine	30, 40, 104	AGA, AGG
Glycine	16, 56, 69, 136	GGC, GGU
	29	GGA
	46	GGA, GGG
	74	GGA, GGC, GGU
Leucine	3, 96	CUC, CUU
	32	CUN, UUA, UUG
	48, 31	UUG
	75	CUG, UUG
	68, 114, 105, 106, 110, 141	CUA, CUC, CUU, UUA
	78	CUA, CUG, UUA, UUG
	81, 28, 14, 88, 91	CUN
Proline	51, 58, 125	CCA, CCG
	100	CCA, CCC, CCU
Serine	9	UCU, UCC
	89	UCN
	44, 72	AGC, AGU
	49	UCA, UCG
Threonine	4, 84, 86	ACA, ACG
	12, 50, 123	ACC, ACU
Valine	1, 113, 126, 98	GUG
	11	GUA, GUC, GUU
	20, 33	GUA, GUG
	23, 34, 109, 111, 134, 137	GUC, GUU
	133	GUG, GUC, GUU
	54, 67	GUA

Perhaps the most interesting finding is that GUG is the most probable codon for the amino-terminal valine. In *Escherichia coli*, GUG codes for formylmethionine and at the 5′ end of mRNA serves as the initiator codon for protein synthesis[14]. The fact that valine rather than methionine is found in the N-terminal position of the β chain can be explained by the apparent absence of formylmethionyl-tRNA in the cytoplasm of cells of higher organisms[15]. These considerations predict that if formylmethionyl-tRNA were available it would initiate β chain synthesis on a mammalian ribosome and that formylmethionine would be substituted for the normal N-terminal valine.

I thank Dr I. B. Weinstein for criticisms and Dr L. M. Fink for discussions. This work was supported in part by a National Cancer Institute US Public Health Service grant.

Model for Quantitative and Qualitative Control of mRNA Translation in Eukaryotes

In a recent communication by Griffith and Mahler[1] dealing with a ticketing theory of memory, the authors mentioned that their model stemmed from a hypothesis previously advanced by us in order to account for certain features of the process of translation in eukaryotic cells. This hypothesis has been briefly noted[2] but not adequately described and is therefore presented here in detail.

The hypothesis was originally suggested by experiments designed to study the accumulation of a variety of enzymes at different stages of cellular slime mould morphogenesis. The results indicated that there is in each case a stoichiometric relationship between how much transcription is permitted and how much of a particular enzyme subsequently accumulates[3,4]. The RNA product of one of these periods of transcription, normally stable for 4–5 h before actual accumulation of the corresponding enzyme, was found to remain stable several hours longer if one added and then removed cycloheximide, a reversible inhibitor of protein synthesis. There was no significant reduction in the level of enzyme activity accumulating thereafter[5].

These findings prompted the postulate that every molecule of mRNA, at least in eukaryotic cells, has at its 5′-hydroxyl end a set of redundant base sequences. In Fig. 1, these are schematically designated as triplets but might be, and probably would be, much longer. Each of these sequences would serve as the attachment site for a ribosome. As the ribosome moved down the length of the molecule, one of the ribosomal proteins, an excising enzyme, would clip and release the first of the redundant sequences. This ribosome would then pass along the polynucleotide chain and, having reached an initiation codon, would begin polypeptide synthesis. Meanwhile, a second, third and fourth ribosome would successively attach and in turn excise the then terminal redundant sequence. After excision of the last redundancy, no additional ribosomes could attach, and the mRNA molecule would be open to degradation by nucleolytic attack. Two considerations follow from this model.

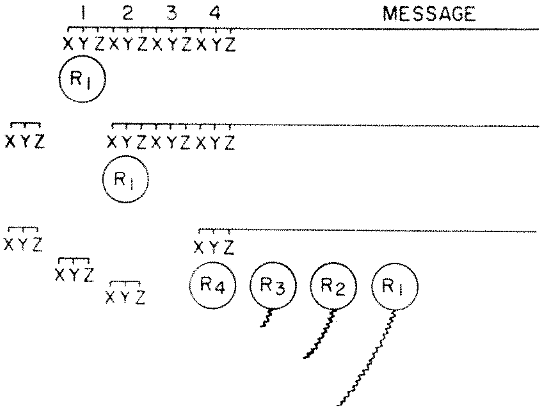

Fig. 1. XYZ represent purine or pyrimidine bases within a redundant trinucleotide sequence. In the example shown, four such sequences occupy the 5′ end of a molecule of mRNA. R_1 to R_4 represent ribosomes successively attaching to the mRNA. Each such attachment results in the excision of one of the redundant sequences.

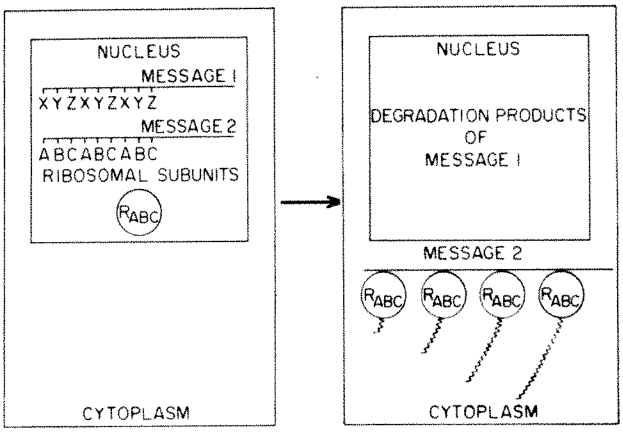

Fig. 2. Redundant sequences XYZ and ABC at the 5′ termini of mRNA molecules 1 and 2, represent attachment sites for different classes of ribosomes R_{XYZ} and R_{ABC} respectively. Only the latter are present in the cell. Only mRNA molecule 2 can therefore be conveyed into the cytoplasm and translated while mRNA molecule 1 remains in the nucleus until it is degraded.

First, the model would provide for automatic digital control over the level of a particular enzyme that accumulates in a cell when it follows a specific developmental programme. This is consistent with, for example, the patterns of enzyme accumulation observed during cellular slime mould morphogenesis[2] and in the cell growth and division cycle of *Saccharomyces cerevisiae*[6].

Second, mRNA molecules transcribed from different genes might contain different numbers of the redundant base sequence at their 5′ termini. This would enable a cell to possess mRNA molecules with different stabilities and thus automatically to accumulate different levels of the corresponding proteins. Mutations, deletions or additions in the redundant region could conceivably permit natural selection to operate, and in this manner regulate the quantity of a particular protein in a cell.

The model can be expanded to provide for qualitative as well as quantitative control of protein synthesis. As schematically illustrated in Fig. 2, more than one kind of redundant base sequence might occupy the 5′ termini of different mRNA molecules in a given cell. These could serve as specific, mutually exclusive attachment sites for different classes of ribosomes. Thus a cell might be potentially capable of engaging in either of two alternative developmental programmes, each leading to a specific differentiated state. mRNA molecules appropriate to one developmental programme might contain one kind of redundant sequence; those appropriate to the alternative programme might contain a second kind. Both classes of mRNA might be transcribed and be present in the nucleus. Fabrication of ribosomes, however, might be restricted to the kind capable of attaching only to the redundant sequence present in one class of mRNA molecules. The result would be that the favoured class of mRNA would migrate to the cytoplasm and be translated; the second class of mRNA, finding no ribosomes to attach to, would remain in the nucleus and eventually be degraded.

This expanded model can conceivably account for three facts which seem to have great significance for the process of cytodifferentiation.

Eukaryotes have highly redundant DNA sequences of the order of 500 nucleotide pairs which are scattered throughout the genome. These are present at frequencies generally ranging between 10^2 and 10^5 copies per genome[7]. Such redundancies might be at least partly accounted for as different classes (and lengths) of nucleotide sequences at the 5′ termini of structural genes.

In the cellular slime moulds, the growth and cell division cycle and the construction of organized multicellular fruiting bodies represent alternative developmental programmes. The second can be carried out in the absence of all exogenous nutrients. It has been found that during fruiting body construction most, if not all, of the ribosomes present in the vegetative cells are destroyed and are replaced by ribosomes made during the morphogenetic sequence[8,9]. This might reflect the need for a new class of ribosomes which could attach to the new class of mRNA molecules. In heterocaryons of HeLa cells and hen erythrocytes (whose cytoplasm had been allowed to leak out before cell fusion), it has been shown[10] that the previously quiescent erythrocyte nuclei synthesized RNA and turned it over for several days, but none was found in the cytoplasm. By contrast the RNA coming from the HeLa nuclei was observed in the cytoplasm. Only after nucleoli developed in the erythrocyte nuclei and ribosome synthesis resumed did hen RNA appear in the cytoplasm and this was followed by the accumulation of hen-specific proteins.

As much as 80–90 per cent of the RNA transcribed during a short pulse of radioactive precursor has been shown to remain within the nucleus, to be highly unstable and to be polydisperse[11,12]. This class of RNA could be accounted for as being the portion of the mRNA lacking the corresponding classes of ribosomes with which to attach.

In summary, the model provides for an automatic, quantitative control over the use of any given mRNA molecule in protein synthesis by assuming the existence of a specified number of ribosomal attachment sites in the form of redundant base sequences at the 5′ terminus, each ribosomal attachment resulting in the excision of one of the redundant sequences. In its expanded form the model provides for qualitative control of protein synthesis by assuming the existence of more than one kind of redundant sequence on different mRNA molecules and more than one class of ribosomes, each capable of recognizing and attaching to one kind of redundant sequence.

The assumption of controls operating at the level of mRNA transport and/or translation does not and need not exclude the existence of a network of transcriptional controls as well. Ingenious models of the latter have been postulated for eukaryotic cells engaged in developmental activities, assuming negative feedback[13], and assuming a positive feedback[14] patterned loosely after the hypothesis of Englesberg *et al.*[15].

Hydrolysis of Phospholipid Esters localized in Lysosomes and Related Structures of Rat Muscle Cells in Culture

THE fusion of normal myoblasts during differentiation of muscle leads to a multinucleated striated muscle fibril. The fusion reaction between cells is not well understood. Almost as soon as contact is made between two myoblasts, the plasma membranes of the two cells fuse to become one continuous plasma membrane surrounding the cytoplasm of both cells. It is not known whether such normal fusion reactions between muscle cells involve hydrolytic enzymes for digestion of carbohydrates, proteins and lipids constituting these membranes at their sites of fusion. The fusion reaction as well as the extensive cytoplasmic changes during differentiation prompted us to investigate digestive functions in our cultured cells using phosphate esters of a variety of compounds. This is the first report of histological localization for hydrolysis of phospholipid esters by cultured cells. Previous cytochemical studies on acid phosphatase in our cultured muscle cells showed an increase in lysosomal reaction product as myotubes formed and have been reported as ancillary observations to biochemical studies[1,2]. Our *in situ* investigations for lipid phosphate hydrolysis were also prompted from reports by Tappel *et al.*[3,4] as well as Fowler and de Duve[5] on digestion of lipids and organelle membranes with isolated rat liver lysosomal particles.

Cytochemical examinations for hydrolysis of phosphate esters from phospholipids were carried out on primary rat muscle cell monolayers grown under the regulated conditions of culture. The cultures showed 50–70 per cent muscle cells interspersed with fibroblasts and the monolayers allowed for a clear localization of phosphatase in both cell types during the culture period from days 3–10. Light and electron microscopic studies were performed on the same cultures by originally plating cells on glass and fluoroplastic coverslips coated with gelatine. The phospholipid ester hydrolysis was found to be localized in lysosomes and in related vesicles after incubation of the cells with substrates at acidic *p*H. The coverslips, on which cells were growing, remained in Falcon plastic culture dishes for all the treatments. They were then mounted for light microscopy and subjected to further treatment for electron microscopic studies.

Cell cultures were washed free of growth medium with cold Pannett–Compton saline, *p*H 7·4. Cold 2·5 per cent glutaraldehyde fixative in 0·1 M cacodylate buffer *p*H 7·2 was then added for 10 min. The fixative was removed with two washings of cold 0·05 M acetate buffer *p*H 4·8. Five ml. of the fresh incubation medium was added to each culture dish. The incubation medium was made by adding 25 mg phospholipid sonically dispersed for 1 min in 5 ml. of glass distilled water to 10 ml. of 0·1 M acetate buffer at *p*H 4·8. Ten ml. of lead nitrate (0·1 per cent) was added to give a final lead concentration of 1·2 mM in 25 ml. completed medium. The following phospholipids were tested: egg lecithin (Mann Research), dipalmitoyl L-α-lecithin (synthetic, A. G. Fluka and Co.), dipalmitoyl-L-α-cephalin (Fluka); L-α-glycerophosphoryl choline (Sigma) was also used. Cytidine 5′ monophosphate was also tested at *p*H 4·8 with an incubation time of 45 min. Control media for long incubation periods were prepared by, first, omitting substrate; second, adding 0·01 M NaF to the medium; and third, using suitable buffers in media at *p*H 6·6 and 7·2 such as Tris-maleate and histidine. No positive reaction product was obvious in the cells in these conditions. The coverslip cultures in the incubation media were placed in a moisture controlled 37° C incubator. Because of the known latency of this type of lysosomal enzyme (see ref. 5), an overnight or 12 h incubation period was required to show the reaction with phase microscopy. After incubation, the cultures for light microscopy were rinsed in cold 0·05 M acetate buffer *p*H 4·8 and immersed in 1 per cent ammonium sulphide for 1 min, rinsed in cold distilled water and mounted in glycerol gel. For electron microscope studies, fluoroplastic coverslips were used[6]. After incubation, the coverslips were thrice washed with acetate–veronal buffer *p*H 7·4. The cells were then post-fixed for 10 min with osmium tetroxide (*p*H 7·4 in acetate–veronal buffer). The cells were dehydrated and embedded in epon–Araldite mixture[7].

With Zeiss phase microscopy, perinuclear localization of the reaction product was evident in fibroblasts of early (4 day) cultures. As the cultures became confluent, the location and apparent visible amount of reaction product did not change in the fibroblasts. In myotubes, the reaction product increased with the age at which the cultures were sampled. This increase in maturing myotubes occurred in lysosomal type deposits, rather than perinuclear deposits in the Golgi zone. As each variation of the procedure was investigated, the cultured cells were checked for reaction product at 2 h and 5 h as well as 12 h and 20 h. Optimal reaction time for light microscopy is at 12 h. No decrease in latency was noted when short fixation times (5 min) with glutaraldehyde were used. As shown in the accompanying figures for electron microscopy, there was deterioration in cell structure.

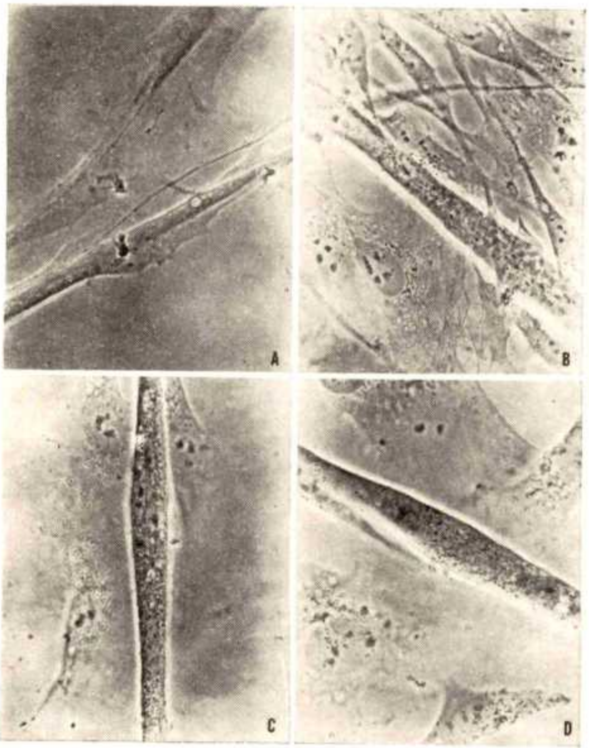

Fig. 1. Photomicrographs *A* to *D* (× 525) are from replicate plates of the same culture. *A*, Fibroblast and early myotube in a culture plate incubated without substrate but in the presence of 1·2 mM lead for 12 h at *p*H 4·8. The cells show no internal deposits; only external artefacts are evident. *B*, Egg lecithin was used as substrate. The deposits in the fibroblasts are perinuclear and in the Golgi region. Deposits in the myotubes are in localized regions of cytoplasm. *C*, Myotube after incubation with synthetic L-*α*-dipalmitoyl lecithin. *D*, Cytidine monophosphate was used as substrate *p*H 4·8, 45 min incubation.

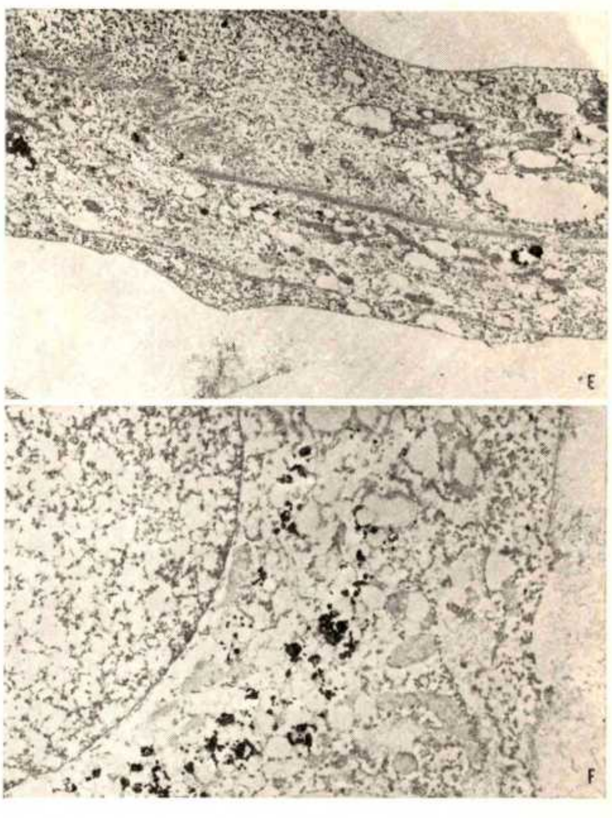

Fig. 2. Synthetic L-*α*-lecithin was used as substrate for the following electron micrographs from the same culture used for photomicrographs *A* to *D*. In *E*, two fusing myoblasts are shown. Note absence of reaction product at the plasma membranes at the common cell boundaries. Product is deposited in lysosomal vesicles. (× 5,000.) *F*, Showing perinuclear reaction product in fibroblast cell. Nuclear membrane shows no reaction. (× 11,000.) Cells were badly preserved through manipulations subsequent to short initial fixation time (5 min) used in this trial and the long incubation in the presence of phospholipid substrate.

Incubation of cells in incubation medium with 0·25 M sucrose was damaging to the enzyme reaction. No improvement was obvious when the incubation medium contained 25 per cent dimethyl sulphoxide. In experimental cell cultures, reaction product is absent in other organelles than lysosomes or Golgi type vesicles. Deposits of reaction product were absent from nuclear or plasma membranes. There was no increase in deposits apparent in regions where muscle cell fusion was taking place as in the accompanying electron micrograph (*E*) where plasma membrane between two fusing myoblasts is clearly seen.

The presence of hydrolytic activity in the Golgi zone and lysosomes of primary cultures of liver cells has also been successfully demonstrated in our laboratory and will be reported elsewhere. The enzyme is quite latent even in this well characterized cell type.

The failure to demonstrate any reaction product associated with membranes of fusing muscle cells with phospholipid substrate is unexpected. (We have had occasional experiments in which an unlocalized deposit in one limb of single muscle cells has been seen. At present we regard this as an artefact.) With a substrate such as ATP, membrane ATPase between adjacent cells can be demonstrated after only a 10 min incubation period. The fusion reaction between cells most likely involves energy of ATP hydrolysis. The fusion process between cells does not seem to involve "digestion" of plasma membranes in differentiating muscle cells.

The fusion process between gametes as well as that induced by viruses should also be investigated histologically. According to Okada *et al.*[8], energy is required for fusion of Ehrlich ascites tumour cells by HVJ virus. Does such a fusion process take place after hydrolysis of membrane constituents or because of involvement of the cell plasma membrane in construction of virus coat? The question with regard to fusion between gametes is all the more interesting because of involvement of the acrosome of the sperm. The origin of the acrosome is from the Golgi region which is one of the cell structures involved in digestion of phospholipid esters.

Electron microscope studies were performed by H. H. Mollenhauer.

Non-enzymatic Hydrolysis of Adenosine Phosphates

ENERGY transfer in living systems usually involves reactions in which adenosine triphosphate (ATP) is converted to adenosine di (ADP) or monophosphate (AMP) and inorganic phosphate. Similar reactions were probably necessary to provide energy for prebiological evolution. Concentrations of these compounds are affected by non-metabolic destruction, principally hydrolysis releasing orthophosphate. Thus the rates of such hydrolysis are of interest with respect both to present living systems and to the origin of life. Hydrolysis of ATP and ADP has been studied previously at selected temperatures and *p*H, both in distilled water and in the presence of several inorganic ions which might act as catalysts[1,2]. The present work is concerned with reactions of ATP, ADP and AMP over a range of temperatures in distilled water, in 0·02 moles Ca^{2+} (previously reported to act as a catalyst), and in a synthetic seawater containing present oceanic concentrations of Na^+, K^+, Ca^{2+}, Mg^{2+}, Sr^{2+}, Cl^-, SO_4, HCO_3^-, Br^- and $H_2BO_3^-$. The latter medium was chosen as being as reasonable a representation as possible of primitive seawater, because the composition of the primitive seas, though not exactly known, was probably not drastically different from that of the present ones[3].

The sample compounds were dissolved in the liquid medium, usually at 0·001 M concentration, and *p*H adjusted by addition of NaOH or HCl (0·1 moles). The solutions were then incubated at the desired temperatures and the rates of hydrolysis determined by analysing for inorganic orthophosphate by the method of Lowry and Lopez[4]. Less than 10 per cent of the initial compound was hydrolysed in each case, to ensure that the amount of phosphate split off would be linearly related to initial concentration and that little phosphate would be split from degradation products (for example, from ADP in tests on ATP). In some cases checks were run at different concentrations to ensure that the reactions were first order in organic phosphate.

Experimental results are shown in Fig. 1 in which the logarithm of the hydrolysis rate is plotted against the reciprocal of absolute temperatures (to give a straight line). The rate of hydrolysis of ATP was greatest at low ionic strength in the presence of 0·02 moles Ca^{2+} ions, as shown by curve 1. Hydrogen ions also catalysed the reaction as shown by the comparison of curve 2 in water at *p*H 4, with curve 4 in water at *p*H 8. Hydrolysis in seawater at *p*H 8 (curve 3) is only slightly greater than in pure water at the same *p*H, probably because the catalytic effect of ions like Ca^{2+} is reduced in the high ionic strength solution. ADP is slightly more resistant to hydrolysis at high temperatures than ATP, with very similar rates in water and in seawater, as shown by curves 5 and 6. AMP is much more resistant to hydrolysis than ADP, with a lower rate in seawater than in pure water, as shown by curves 7 and 8. In order to illustrate the relationship between life of these compounds and temperature, the scale on the right has been added, giving half-life for various reaction rates. The experimental results in the synthetic seawater have been extrapolated to temperatures encountered in the present environment. Of all the compounds, only AMP would be expected to survive in such solvents for more than a few years at temperatures near present ambient.

The composition of the synthetic seawater used is probably not exactly that of the primitive oceans. The facts that hydrolysis in this high ionic strength medium is very close to that in water and that some of the ions (for example, Ca^{2+}, which is the most abundant cation in fresh water) catalyse the reaction in low ionic strength solutions, however, indicate that rates of hydrolysis in the primitive oceans and lakes would have been of the same order of magnitude as those found. Thus a long term build-up of these compounds would not be expected in the prebiological environment. In addition the relatively short life at high temperatures indicates that the origin of life would have been facilitated by cold environments, at any rate as far as participation by ATP and ADP is concerned.

Also of interest is the extremely short life of ATP—of the order of a few hours or less—at temperatures above 90° C, even though bacterial growth has been reported at these temperatures[5]. Unless thermophilic organisms have intracellular environments capable of slowing down the reaction appreciably, a major limitation on the maxi-

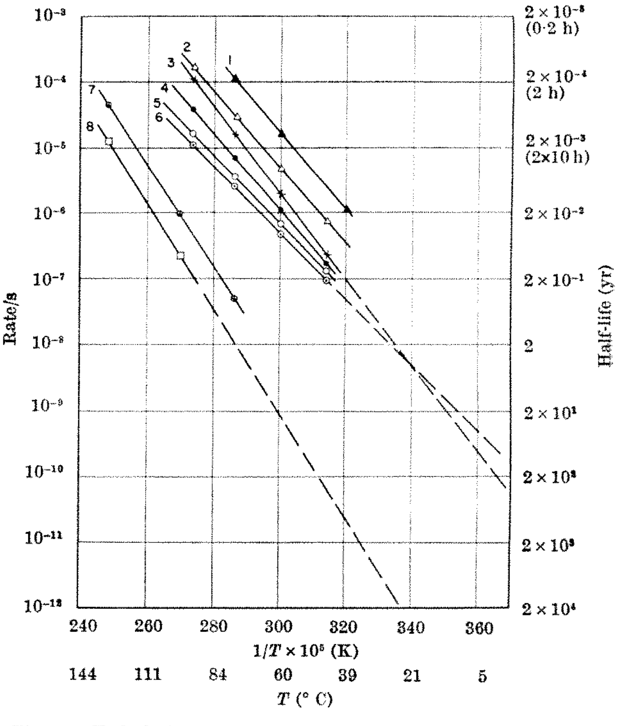

Fig. 1. Hydrolysis rates of nucleoside phosphate as a function of temperature. 1, ATP, *p*H 8, in 0·02 moles Ca^+; 2, ATP, *p*H 4, in H_2O; 3, ATP, *p*H 8, in synthetic seawater; 4, ATP, *p*H 8, in H_2O; 5, ADP, *p*H 8, in H_2O; 6, ADP, *p*H 8, in synthetic seawater; 7, AMP, *p*H 8, in H_2O; 8, AMP, *p*H 8, in synthetic seawater.

mum temperature at which life is possible may be non-enzymatic hydrolysis of ATP.

Possible Basis for the Cariostatic Effect of Inorganic Phosphates

INORGANIC phosphates are effective in reducing dental caries when added as supplements to cariogenic diets fed to rodents[1], and when added to chewing gum[2] and to breakfast cereal eaten by children[3]. Because the caries process may be influenced by pellicle proteins[4], and salivary proteins adsorbed to human enamel are differentially eluted by water and orthophosphate solutions[5], we reasoned that the cariostatic effect of phosphate might involve one or both of the following processes: (*a*) differential elution of proteins adsorbed on enamel; (*b*) modification of the enamel surface resulting in an alteration of the acquired protein layer. To test this hypothesis in a model system we have studied the effects of phosphates on enzymes adsorbed to human enamel.

Samples (50 mg) of purified human enamel powder[6] were equilibrated at room temperature with 1 ml. of a 0·1 mg/ml. solution of purified amylase (from *Aspergillus oryzeae*). The supernatant was decanted and the enamel samples were washed with 1 ml. of water, or with 1 ml. of saturated $CaHPO_4$ solution (1·8 mM)[7], or with 1 ml. of 1·8 mM solutions of either NaH_2PO_4 or $Na_3(PO_3)_3$. All solutions were at *p*H 6·0. Each of four successive 1 ml. washings was assayed for desorbed amylase activity. (We have found that the presence of these phosphates at a concentration of 1·8 mM does not interfere with the normal expression of amylase activity.) The results are shown in Table 1.

Table 1. DESORPTION OF AMYLASE FROM HUMAN ENAMEL

Wash number	Units* of amylase desorbed from 50 mg of enamel powder by 1 ml. washes of:			
	H_2O	$CaHPO_4$	NaH_2PO_4	$Na_3(PO_3)_3$
1	0·24	0·60	1·53	2·05
2	0·19	0·30	0·64	0·73
3	0·00	0·13	0·18	0·17
4	0·00	0·08	0·10	0·00
Total desorbed in four washes	0·43	1·11	2·45	2·95

* 1 unit of amylase catalyses the release of 1 mM of maltose per min from a 1 per cent soluble starch solution at 25° C. The phosphate concentrations were 1·8 mM.

Water desorbed very little amylase. The activity in the first eluant portion is probably the result of amylase remaining in the interstitial fluid after removal of the supernatant. Desorption effectiveness of the solutions was in the order $Na_3(PO_3)_3 > NaH_2PO_4 > CaHPO_4 > H_2O$. Similar desorption studies were made with purified hen's egg white lysozyme. Lysozyme was not desorbed by any of the 1·8 mM phosphate solutions, but was desorbed by sodium orthophosphate at a concentration of 40 mM and by 1 per cent (by weight) sodium trimetaphosphate (TMP) solutions.

We investigated the possibility of surface modification by pretreating enamel with 1·8 mM phosphate solutions before adsorption of the enzymes. Only TMP altered the adsorption properties of the enamel. Amylase adsorbed to TMP treated enamel was easily removed by water, and TMP treated enamel adsorbed 2 to 3 times as much lysozyme activity as untreated enamel. The alteration of the enamel surface by trimetaphosphate was not a simple detergent effect. Pretreatment of enamel with either a 0·1 or 1·0 per cent (by weight) solution of 'Triton *X*-100' (isooctylphenoxypolyethoxyethanol, a biodegradable non-ionic, surface active agent) had no effect on subsequent enzyme adsorption by the enamel. In the mouth, salivary proteins adsorbed on the tooth surface[9] might protect enamel from alteration by phosphate. We found, however, that solutions of TMP produced the same effects on enamel powder which had first been equilibrated with centrifuged whole saliva.

While our results do not exclude the possibility of other mechanisms of action, they support the hypothesis that the basis of the cariostatic effect of inorganic phosphates is a modification of the composition of the protein layer adsorbed on enamel and, in the case of TMP, an alteration in the surface of the enamel with resulting change in the affinity of various salivary proteins for the enamel surface.

We thank Dr Charles Bugg of the Institute of Dental Research for initially drawing our attention to this problem and for discussion.

Production of "Sulphation Factor" by the Perfused Liver

LONGITUDINAL growth of the mammalian skeleton occurs at the epiphyseal plate where chondrocytes proliferate and synthesize a matrix composed of collagen and a group of sulphated polysaccharides. In spite of the well known requirement for growth hormone to sustain longitudinal skeletal growth, a direct effect of the hormone on cartilage metabolism has not been demonstrated. The incorporation of sulphate into the organic matrix of cartilage is stimulated by a component of normal serum which is not growth hormone. This factor is absent in the serum of hypophysectomized animals, including man, but is restored by the administration of growth hormone. In addition to the stimulation of sulphate incorporation into polysaccharide, collagen synthesis and cell replication are also enhanced. Because the original assay for this component involved measurement of the incorporation of radioactive sulphate into the cartilage of hypophysectomized rats, the term "sulphation factor" was proposed by Salmon and Daughaday[1]. The source of this factor as well as its composition have been unknown.

The fact that liver is one of the few tissues which has been shown to respond to growth hormone *in vitro*[2] makes it a likely source of sulphation factor. The work reported here demonstrates that the liver is capable of producing sulphation factor during perfusion with bovine growth hormone (BGH).

The livers of normal adult rats were perfused *in situ* (F. Chavez-Peon, unpublished technique). The animals were kept alive until the perfusion started, thus reducing the time for development of ischaemia to less than 12 s. The medium used for both perfusions and controls was Waymouth's 'MB 752/1' with 0·5 per cent bovine serum albumin, 100 units/ml. penicillin and 100 μg/ml. streptomycin added. The perfusions took place in two stages: the liver was first washed through with the medium alone, then medium containing 10 μg/ml. of BGH was recirculated three times through the same liver. All solutions were kept at 37° C and the perfusion rate was 3·5–4·5 ml./min. The perfusates were collected separately at the end of each stage; red cells were sedimented in a clinical centrifuge; and the supernatant was passed through a 'Millipore' filter. Thus sterilized, the supernatant was then kept frozen until assayed.

The ability of these solutions to stimulate the uptake of radioactive sulphate into the costal cartilage of hypophysectomized rats was then tested using a modification of Salmon and Daughaday's sulphation factor assay[3]. The cartilage segments were incubated in the various media with radioactive sulphate for 48 h, after which they were washed thoroughly, scraped to remove excess fibrous tissue, weighed after blotting and hydrolysed in 23 M formic acid. An aliquot of the hydrolysate was added to a scintillation mixture and radioactivity was counted in a liquid scintillation counter. Separate experiments to provide histological material were carried out and autoradiographs were prepared with Kodak 'NTB-2' liquid emulsion.

The incorporation of ^{35}S from medium containing perfused BGH was compared with that in three controls: 1, medium with no additions, not perfused; 2, medium containing 10 μg/ml. BGH but not perfused through the liver; 3, plain medium perfused through the liver. It was necessary to recirculate the BGH through the liver three times to produce a measurable effect, but recirculation of medium without BGH failed to produce any increase in its effect.

The results are shown in Fig. 1. Each bar represents the mean of six determinations of ^{35}S uptake from each of six liver perfusions and their controls. The small increases seen with exogenous BGH and with perfusion of plain medium are not statistically significant whereas that seen with the perfused BGH is highly significant ($P < 0{\cdot}01$). These results are confirmed by the autoradiographs shown in Fig. 2. Little ^{35}S activity is seen in the controls, while intense labelling is evident in the matrix of cartilage incubated with medium containing perfused growth hormone.

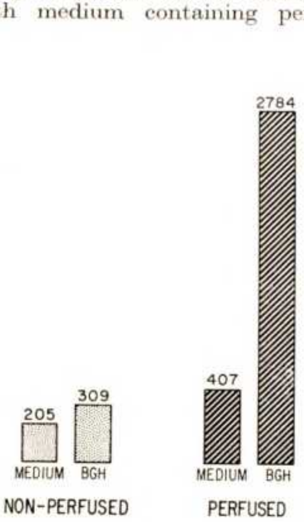

Fig. 1. The incorporation of $^{35}SO_4$ into the organic matrix of rib cartilage of hypophysectomized rats, measured in c.p.m./100 mg. The first two bars show the uptake from media with and without growth hormone, not perfused through the liver. The third and fourth bars show the result of perfusing these media through the liver.

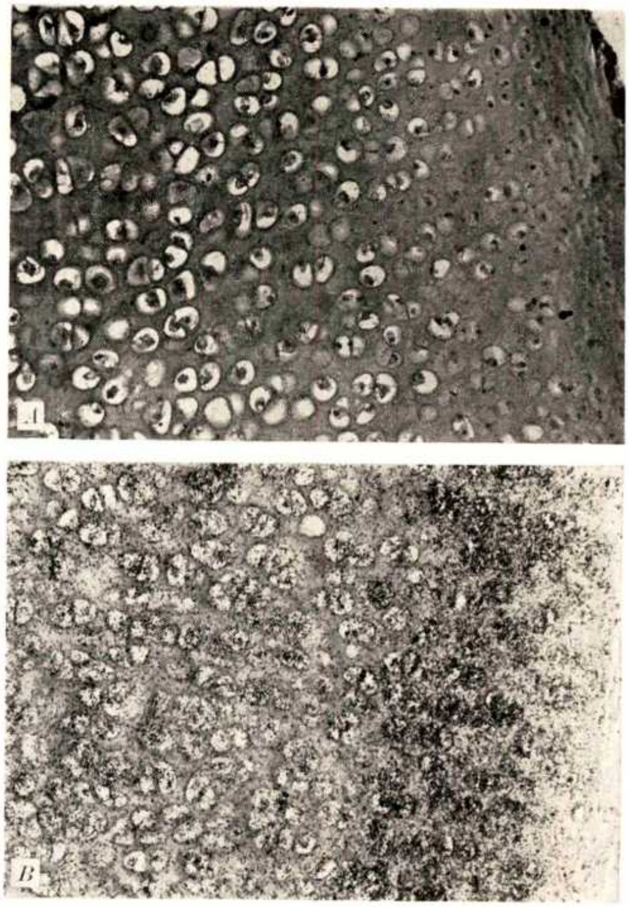

Fig. 2. ^{35}S autoradiographs of incubated cartilage. *A*, Perfused medium; *B*, medium plus BGH, perfused through the liver.

What is "sulphation factor"? Is it an altered form of growth hormone, the result of conjugation or degradation, or is it a second hormone released in response to growth hormone stimulation of the liver? We have no clear answers, but the reported increase in liver DNA and RNA following perfusion with growth hormone, in conjunction with our finding that fairly prolonged exposure of the liver to growth hormone is required, is compatible with the hypothesis that sulphation factor is a distinct hormone chemically unrelated to growth hormone.

Table 1. UPTAKE OF $^{35}SO_4$

	C.p.m./100 mg net weight cartilage			
	Not perfused		Perfused	
	Control	Growth hormone	Control	Growth hormone
Number	24	24	36	36
Mean c.p.m.	205	309	407	2,784
S.E.	±34	±34	±50	±199

We thank Miss Sonya Shortkroff and Miss Sandra Perlstein for assistance and Dr F. Chavez-Peon for performing the liver perfusions. BGH was supplied by Dr A. E. Wilhelmi. This work was supported by a general research support grant from the National Institutes of Health, US Public Health Service.

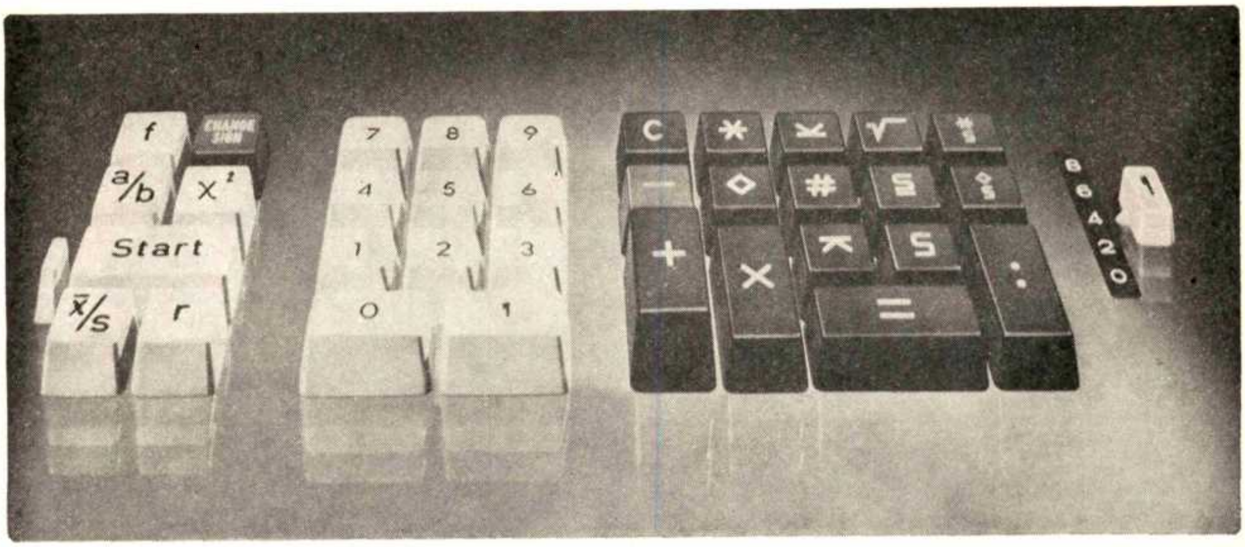
DIEHL sigmatron

Electronic Calculating System with Pre-programmed Statistical functions



DIEHL sigmatron is the first calculating system specifically designed for Statistical calculations. By pre-programmed functions, Statistical calculations are reduced to one key operations. For instance, to obtain the Arithmetic Mean and Standard Deviation enter data on the keyboard and touch the pre-programmed key. After entry of the data is completed you need only touch the same pre-programmed key to obtain the results immediately. Linear Regression, Chi Square, Coefficient of Correlation are all reduced to the simplicity of one key operation. DIEHL sigmatron also gives you a powerful and effective calculating performance with ten separate memories, automatic square root, automatic decimal selection up to 8 places and a complete check of each figure, each step and each result. If you prefer to make your own programs, DIEHL combitron S has 10 Program/Memory registers providing a capacity of 120 steps with branching and looping. For external input of data, DIEHL dilector – punched tape reader – is available.

Quantitative information on cell structures, fast, with the Barr & Stroud Integrating Microdensitometer GN2 –in use all over the world

Cells stained by the Feulgen method absorb light in direct proportion to their mass. By mechanically scanning the image of a stained specimen, and electronically integrating the values for the whole image, an absolute measure of absorption in arbitrary units is obtained. Similar measurements can also be obtained on other cell properties.

The Barr & Stroud Integrating Microdensitometer type GN2 has been designed to use this principle to provide quick, accurate, quantitative information on cell structures. It has gained wide acceptance throughout the world, particularly for Cancer research, where large numbers of specimens must be examined quickly.

Binding Activity of Oestrogen Receptors destroyed by Iodination

WHEN 17β-oestradiol and other oestrogens enter a target cell they are bound by highly specific oestrophilic proteins in a strong but non-covalent manner ($K_{ass} \simeq 1{\cdot}3 \times 10^9$–$1{\cdot}5 \times 10^9$ M^{-1} for 17β-oestradiol)[1]. These oestrogen receptors are found in both nuclear and cytoplasmic fractions of uterus and other target organs to this hormone[1-11]. We now report (1) that iodination of calf uterus oestrogen receptors in alkaline media at lowered temperature destroys their ability to bind 17β-oestradiol; (2) that this effect cannot be ascribed to oxidation of SH groups; and (3) that iodination is ineffective when the binding site is interacting with the hormone, and is thus protected from a direct effect.

Oestradiol–receptor complexes from the cytoplasmic and nuclear fractions of the same calf uteri were prepared by salting-out with $(NH_4)_2SO_4$, as described elsewhere[7]. *In vitro* reversible dissociation of the oestradiol–receptor complexes was achieved by treatment for 5 min at 42°–45° C; *in vitro* formation of the complexes by incubation at 4° C for 90 min; and separation of oestradiol–receptor complexes from free hormone by chromatography on 'Sephadex *G*-25', as already described[1,6]. ^{3}H-17β-oestradiol (from NENC, Boston; specific activity 42 Ci/mmole; ≥97 per cent pure at time of experiment) was determined by liquid scintillation as described[1,6]. Iodination was carried out with 0·037 M I_2 in 0·214 M KI, which was standardized against $AgNO_3$ (ref. 12) and $Na_2S_2O_3$. When required, the iodide solution was labelled with carrier-free ^{131}I (NENC). The following conditions were used throughout: 0·2 mg protein of receptor preparation per ml. of 0·1 M Tris-HCl (*p*H 8·5), 10^{-2} M KCl, 10^{-3} M EDTA (Tris-K$^+$-EDTA medium); the *p*H remained unchanged during iodination, which was stopped by adding 5 moles of $Na_2S_2O_3$ per mole of I_2. ^{131}I was determined in a well type scintillation counter. Protein was determined by a modification of the biuret reaction[13]. Iodoacetate was recrystallized from petroleum ether before use. The activity of L-malate dehydrogenase from pig heart was measured with oxaloacetate as substrate by the decrease of absorbance at 366 nm arising from oxidation of NADH (ref. 14).

An inverse correlation was found between amount of organic iodine formed and ability of a preparation of oestrogen receptor from the nuclear fraction to bind 17β-oestradiol (Fig. 1). One can see that maximal iodination of the preparation corresponds to a virtually total loss of binding activity. Also, our data show that the formation kinetics of organic iodine coincide with the kinetics of inactivation of the ability to bind. I_2 also destroys the binding activity of receptor from the cytoplasmic fraction (Table 1).

Hughes[15] found that during iodination of a protein the sulphydryl groups are oxidized before any iodine is coupled; this reaction could not therefore account for the observed loss of ability to bind 17β-oestradiol with progressive iodination. SH reagents in a variety of experimental conditions were never found able to prevent formation of the oestradiol–receptor complex nor to destroy the preformed complex (Table 1). In an experiment with *P*-mercuribenzoate ion and iodoacetamide, sufficient L-malate dehydrogenase was added as an internal standard to receptor preparations; the enzyme was always strongly inhibited while receptor binding activity was unaffected. Differences from the data of others[16] could be explained by the finding that in our hands a concentration of 1 mM *p*-mercuribenzoate ion induces aggregation of receptor molecules; the aggregates sediment to the bottom of 5–20 per cent sucrose gradients after 12 h at 60,000*g*.

To determine whether the destruction of binding ability of receptor molecules on iodination results from a substitution reaction of a residue or residues within the binding site, or at a different site(s) with secondary effects on the conformation of the binding site, the effect of I_2 was also tested on preformed oestradiol–receptor complex, that is, with the binding site protected from a direct effect. This method is commonly used in covalent labelling of active sites of enzymes and antibodies[17]. The results show that the binding site is protected when interacting with the hormone (Table 1), and we conclude that inactivation of binding activity by iodination is a consequence of destruction of a residue or residues at or near the binding site.

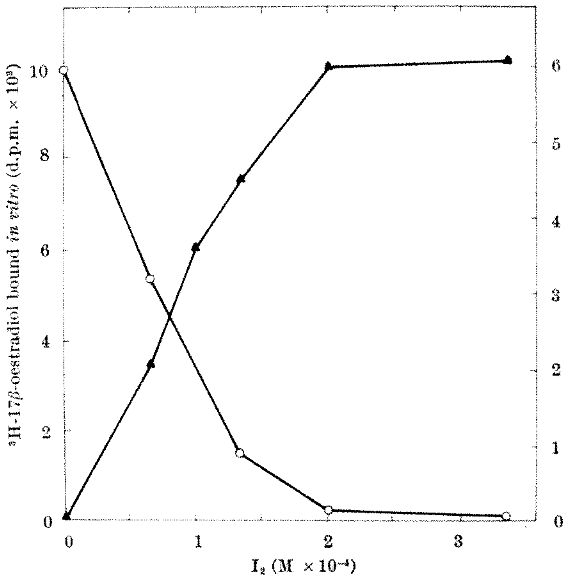

Fig. 1. Correlation between amount of organic iodine formed and ability to bind ^{3}H-17β-oestradiol by receptor preparation from calf uterus nuclear fraction. Aliquots containing 0·2 mg protein/ml. of Tris-K$^+$-EDTA medium (*p*H 8·5) were iodinated for 1 h at 2°–4° C with either unlabelled or labelled tri-iodide solution; after stopping iodination, 6×10^5 d.p.m. of 6,7-^{3}H-17β-oestradiol were added to the samples iodinated with unlabelled tri-iodide; after 90 min at 2°–4° C, unreacted reagents and free ^{131}I or ^{3}H-17β-oestradiol were removed by gel filtration on 'Sephadex *G*-25' columns of standard size (diameter 1·2 cm; total volume 20 ml.) at 4° C; the macromolecular, breakthrough peak was assayed for either ^{3}H (○—○) or ^{131}I (▲—▲) to assess iodine or hormone bound to macromolecules.

Table 1. EFFECT OF SH REAGENTS AND I_2 ON BINDING ACTIVITY OF CALF UTERUS OESTROGEN RECEPTORS WITH BINDING SITE EITHER PROTECTED BY 17β-OESTRADIOL OR UNPROTECTED

Reagent (mM)	Temperature (° C)	Incubation time (h)	*p*H	17β-Oestradiol binding activity (per cent of control)* Nuclear	Cytoplasmic
	Receptor (oestradiol-free)				
p-Mercuribenzoate (0·5)	4–19	1–2	7·8–8·5	93–106	92–101
N-Ethylmaleimide (1)	19	2–16	7·8–7·9	96–103	97–100
Iodoacetate (5)	19	1–16	6·7–8·9	95–102	96–99
Iodoacetamide (5)	19	1·5	7·8	102–104	—
I_2 (0·2)	4	1	8·5	6–14	12–14
	Oestradiol–receptor complex				
p-Mercuribenzoate (1)	4	1	8·5	96–113	94–96
N-Ethylmaleimide (1–5)	4	1	8·5	89–104	—
I_2 (0·2)	4	1	8·5	116–128	116–121

* At least three tests were carried out, and values of maximal variations from control in corresponding series are given.

Oestradiol-free receptor was obtained by heating of native complex for 5 min at 42° C, followed by filtration on 'Sephadex *G*-25' at room temperature to eliminate free oestradiol: the efficiency of this treatment was about 89 per cent of hormone removed. Sequences of treatments with SH reagents were as described in text for iodination, except that treatment by SH reagent substituted for the iodination step. Iodoacetate was freshly recrystallized from petroleum ether. The activity of SH reagents was checked on sensitive enzymes.

Histidyl residues may be as reactive toward I_2 as tyrosyl residues[15], and may be iodinated simultaneously[18]. I_2 is also known to oxidize tryptophyl residues, although tryptophan in general is destroyed after iodination of tyrosyl and histidyl residues[15], and this is in disagreement with the coincident formation of organic iodine and inactivation of binding activity. Furthermore, the relatively high pH used in these experiments is unfavourable to this reaction[19].

We therefore conclude that a tyrosyl and/or a histidyl residue at or near the binding site is essential for binding of 17β-oestradiol by oestrogen receptors; involvement of tryptophan is unlikely. These results agree with the theoretical expectation of Engel[20] that a tyrosyl residue is involved at or near the site of binding of the aromatic end of the steroid molecule.

This work was supported by the Consiglio Nazionale delle Ricerche, Roma. We thank Dr I. Covelli for help with iodination methods and G. Santarpia for technical assistance.

Differential Inhibition of Rat Liver Cholesterol Biosynthesis by Plant Growth Retardants

To investigate the action of plant growth retardants more precisely, cell-free rat liver preparations have been used as models of plant systems[1]. At least some of the retardants inhibited the enzymes of the isoprenoid biosynthesizing pathway by which radioactive acetate and mevalonate are incorporated into cholesterol. Inhibition of the isoprenoid biosynthetic route[2] that leads to the formation of gibberellins[3] thus seemed to be one of the main effects of applying the retardants to plants[4]. I have expanded the earlier results and here summarize the effects of five plant growth retardants.

Male hooded and albino Wistar rats were used throughout and, after killing by stunning, the livers were excised, weighed, minced and homogenized. The homogenizing medium consisted of 28 mM nicotinamide, 7 mM $MgCl_2 \cdot 6H_2O$, 126 mM sucrose in 44 mM KH_2PO_4–K_2HPO_4 buffer (pH 7·4). A volume equivalent to twice the weight of the liver was used, and after homogenizing for 30 s in a chilled, loose-fitting, mechanically driven glass homogenizer, the homogenate was centrifuged at 3,000 r.p.m. (1,400g) for 5 min. Each 25 ml. incubation flask contained 2 ml. tissue supernatant, 3 ml. phosphate buffer, 1 mg each of ATP, NAD and NADPH, 5,000 µg retardant and either 10 µCi sodium ^{14}C-acetate (30 mCi/mmole) or 0·5 µCi ^{14}C-(+,−)-mevalonic acid lactone (5·03 mCi/mmole). The flasks were loosely stoppered and mechanically shaken at 35° C for 3 h.

Adding 2 ml. 30 per cent KOH terminated the reactions, and the mixtures were then saponified at 35° C for 16 h. The incubations were made 50 per cent with respect to ethanol, carrier cholesterol was added, and the contents were partitioned three times with 25 ml. portions of petroleum ether (b.p. 60–80°). The petroleum ether extracts were reduced to dryness under N_2 and the residues were dissolved in 3 ml. acetone–ethanol (1 : 1). Cholesterol was precipitated by adding 1·5 ml. of 1 per cent digitonin in 55 per cent ethanol, and 3 h later adding a further 2·5 ml. of 0·4 per cent digitonin in water. After 21 h at room temperature the solution was filtered on Whatman No. 1 and the precipitate was washed once with 10 ml. acetone–ether (1 : 1) and three times with 10 ml. ether. The filter papers were treated with 3 ml. pyridine for 1 h at 60° C and then extracted with 20 volumes (60 ml.) petroleum ether. The ether was removed under N_2 and the residue dissolved in 0·2 ml. chloroform–methanol (1 : 1) and 25 µl. aliquots (in Bray's scintillation mixture)[5] were counted. (In two thin layer chromatography solvent systems, 90–95 per cent of the radioactivity in the chloroform–methanol solutions moved with the cholesterol standards.)

Table 1. GROWTH RETARDANT-INDUCED INHIBITION OF PRECURSOR INCORPORATION INTO CHOLESTEROL BY CELL-FREE RAT LIVER PREPARATIONS

Retardant (1,000 µg/ml.)	Percentage inhibition of incorporation in 3 h incubation Acetate	Mevalonate
'Phosphon S'	97 (4)*	38 (2)
'Phosphon D'	99 (6)	89 (7)
'B995' (Alar)	0 (4)	0 (2)
'Amo 1618'	99 (5)	93 (3)
'CCC' (Cycocel)	30 (6)	0 (4)

* Number of replicates.

Table 1 contains the results of a number of experiments with five retardants at a single concentration (1,000 µg/ml.), with either acetate or mevalonate as cholesterol precursors. The retardants at this concentration differ significantly in their capacity to inhibit cholesterol biosynthesis from the two precursors. All retardants except 'B995' inhibit cholesterol formation from acetate. The incorporation of mevalonate (which is further along the biosynthetic pathway) is not, however, inhibited by this concentration of 'B995' or 'CCC', and the effects of 'Phosphon S' are appreciably reduced. It is interesting that substitution of the phosphonium group in 'Phosphon D' by a quaternary nitrogen ('Phosphon S') markedly decreases the effectiveness of the molecule for inhibitory action with mevalonate. Although 'B995' is not inhibitory at this concentration with either precursor, at double the concentration (2,000 µg/ml.) it also suppresses acetate and mevalonate incorporation. 'CCC', on the other hand, even at the higher dose level, does not inhibit the formation of cholesterol from mevalonate. No accurate compilation of dose–response relationships of these retardants on plants has been made, but their general phytoactivity seems to parallel roughly their capacity to inhibit the incorporation of precursors into cholesterol by cell-free rat liver preparations.

These plant growth retardants must now be recognized as cholesterol (and, consequently, steroid) biosynthesis inhibitors, making them comparable in action as well as structure to the animal steroid biosynthesis inhibitors such as 'SK and F 7997-A_3', 'SK and F 7732-A_3' and 'SK and F 525'[6]. The similarity in action between these two groups of compounds has been extended by the findings that 'SK and F 7997-A_3' and 'SK and F 525' exert retardant-like activity on peas[7], tobacco[8], wild cucumber[9] and the fungus *Gibberella fujikuroi*[10].

Although these results suggest a common mode of action for the retardants in plants and animals, it is unlikely to be their only action. It is also unlikely that all plants (and, for that matter, all animals) are equally sensitive. The pronounced differences in species specificity with respect to retardant application effect[11] amply support this conclusion. Differences in response may result from differences in the metabolism of accumulated precursors, or even from completely different types of effects[12]. In connexion with the latter point, unpublished information with J. Sabine shows that 'Phospon D' may inhibit the formation of long-chain fatty acids as well as isoprenoid derivatives.

In spite of the possible diversity of individual retardant effects, the universality of the general effect on isoprenoid metabolism is attested to by the responses of a wide range of organisms. Isoprenoid biosynthesis in the fungus, *Gibberella fujikuroi*, is inhibited[13]; similar inhibition has been recorded in higher plants[14]; reports of effects of retardants on reproductive physiology of houseflies[15], cotton leaf worms[16], aphids[17,18] and locusts[19] can also be easily interpreted as responses induced by inhibited steroid metabolism; and, finally, this communication and earlier results[1] extend this aspect of retardant action to a mammalian system.

The activity of retardants as inhibitors of steroid biosynthesis raises important problems with respect to their agricultural utility. Several of the retardants are not rapidly metabolized by plants[11], and at least one is accumulated and concentrated in particular plant tissues[20]. Unpublished work with J. Sabine also shows that at least two retardants are effective cholesterol biosynthesis inhibitors when applied to rat liver slice systems, as well as in cell-free liver preparations. These findings strongly support the necessity for caution in the large-scale use of retardants for agricultural purposes.

I thank Mr G. Leyson and Miss Nancy Joseph for their technical assistance and the Australian Barley Improvement Trust Fund for its continued support. Part of this work was made possible by a grant from the US National Science Foundation.

Soluble Nitrogenase from Vegetative Cells of the Blue–Green Alga *Anabaena cylindrica*

REPORTS of nitrogen fixation by blue–green algal species have, in the main, been restricted to members of the orders Nostocales and Stigonematales[1]. Unless they are grown in the presence of large concentrations of free ammonium ions, all the species produce characteristic types of cells called heterocysts. The correlation between the ability of a species to fix nitrogen and the possession of heterocysts has led to the suggestion that the heterocyst is the site of nitrogen fixation in blue–green algae[2].

Attempts to obtain active cell-free nitrogenase preparations from blue–green algae have previously resulted in preparations with low activities only, and the activity has been associated with a large particulate fraction[3,4]. Stewart *et al.*[4] were unable to obtain soluble nitrogenase from blue–green algae using sonic oscillation to break the cells. The heterocysts were not broken by sonic oscillation, and it was suggested that this was why enzyme activity was not obtained. The results were considered as evidence that the heterocyst is the site of nitrogen fixation. We have reinvestigated the nitrogenase activity of cell free extracts and have obtained active preparations using sonic oscillation, suggesting that nitrogenase is not restricted to the heterocysts but is also present in vegetative cells.

Anabaena cylindrica (obtained from Dr P. Fay of Westfield College, London) was grown in a medium free of combined nitrogen[5] which was bubbled continuously with 95 per cent N_2, 5 per cent CO_2 for four days. 40 l. of culture was harvested, resuspended in 8 l. of sterile medium and bubbled with 95 per cent argon, 5 per cent CO_2 for 40 h. The argon/CO_2 treatment increased the nitrogenase activity of the culture ten-fold, but did not qualitatively affect the results. The culture was then harvested and the cell paste was either used directly or stored frozen until required.

Extracts were prepared by suspending the cell paste 1 : 4 (w/v) in 0·02 MK N-2 hydroxyethyl piperazine N^1-2-ethanesulphonic acid (HEPES) buffer, *p*H 7·3. After gassing the suspension with nitrogen for 2 h, 1·0 µmole/ml. of $Na_2S_2O_4$ was added and the suspension was exposed to sonic oscillation for 5 min with a Dawe Soniprobe on setting 8; the initial temperature was 10° C. The suspension was then centrifuged for 10 min at 40,000*g* and the supernatant used without further treatment. Nitrogenase activity was assayed using the reduction of acetylene to ethylene[6].

Table 1. REQUIREMENTS FOR ACETYLENE REDUCTION BY EXTRACTS OF *A. cylindrica*

Treatment	nmoles ethylene formed
Complete	218
ATP omitted	0
$MgCl_2$ omitted	0
Creatine phosphate and creatine kinase omitted	0
$Na_2S_2O_4$ omitted	3

The reaction mixture contained, in a final volume of 1·5 ml., HEPES buffer potassium salt, *p*H 7·3, 100 µmoles; $MgCl_2$, 5 µmoles; ATP, 4 µmoles; creatine phosphate, 20 µmoles; creatine kinase, 50 µg; sodium dithionite, 2·5 µmoles; 40,000*g* supernatant fraction containing 6·5 mg protein. The gas phase was 90 per cent argon : 10 per cent acetylene. The reaction was carried out in 7·0 ml. glass vials sealed with 'Subaseal' rubber stoppers. After incubation for 20 min at 30° C the reaction was stopped by injecting 0·1 ml. 60 per cent $HClO_4$ and the ethylene assayed.

Table 1 shows the requirements for acetylene reduction by the 40,000*g* supernatant fraction of *A. cylindrica*. The system showed absolute requirements for adenosine triphosphate (ATP), for an ATP generating system and for a low potential reductant, $Na_2S_2O_4$. These requirements are identical to those previously found for bacterial nitrogenase systems[7].

Table 2 shows the distribution of nitrogenase activity in the different fractions from *A. cylindrica* obtained by sonic oscillation followed by centrifugation. About 20 per cent of the original activity of the whole cell suspension is obtained in the crude sonicate. After centrifugation for 10 min at 40,000*g* essentially all of this activity is recovered in the supernatant fraction, only about 5 per cent of the initial activity in the extract being in the sediment. These results are in contrast to those of Stewart *et al.*[4], who report an initial activity less than 1 per cent of that which we have found in our initial extract. Moreover, all of their nitrogenase activity was associated with a fraction sedimenting in 10 min at 5,000*g*, which may correspond to the low activity which we found to be sedimented in our experiments. The chief difference between our experiments and those of Stewart *et al.* seems to reside in the assay procedure used. The concentrations of reagents used in the assays reported in Table 1 were found to be optimal; greater concentrations of either ATP or dithionite were inhibitory to the soluble nitrogenase. Stewart *et al.* used double the ATP concentration employed by us and ten times the dithionite concentration; the latter concentration has been found to be completely inhibitory to the soluble nitrogenase.

Table 2. DISTRIBUTION OF NITROGENASE ACTIVITY IN EXTRACTS OF *A. cylindrica*

Fraction	nmoles C_2H_4/mg N/min	nmoles C_2H_4/ml. of suspension*/min	Percentage of activity of original suspension
Whole cell suspension	75	280	100
Crude sonicate	18	60	21·4
40,000*g* supernatant	19·5	54·5	19·5
40,000*g* sediment	5·5	2·7	1·0

* The concentration of each fraction was equivalent on a volume basis.

The activities of the extracts were assayed as in Table 1. For determination of the activity of the suspension the reaction mixture contained, in a final volume of 1·5 ml., HEPES buffer potassium salt, *p*H 7·3, 100 µmoles; $MgCl_2$, 5 µmoles and 0·1 ml. of cell suspension. After illumination for 30 min at 30° C at a light intensity of 5,500 lux, the reaction was stopped by injecting 0·1 ml. 60 per cent $HClO_4$ and the ethylene assayed.

In agreement with the findings of Stewart *et al.*[4], the sonication procedure used in these experiments was found to break the vegetative cells while leaving the heterocysts intact. Our extraction procedure resulted in a nitrogenase preparation which was not sedimented by centrifugation at 40,000*g* for 10 min and must be assumed to be released from the vegetative cells. The nitrogenase recovered in this fraction represented 20 per cent of the activity of the original cell suspension, which is similar to the soluble nitrogenase activity extracted from a number of bacteria[8]. We think our results imply that most of the nitrogenase activity of blue-green algae is in the vegetative cells and not, as suggested by Stewart *et al.*[4], in the heterocysts. A more detailed report of these experiments will be published elsewhere.

Lack of Porosity of the Mouse Placenta to Maternal Cells

RECENT papers by Tuffrey, Bishun and Barnes[1,2] have evoked great interest, because they have challenged the hitherto conventional views on the integrity of the placental barrier to maternal cells. They first reported finding an often substantial proportion (up to 33 per cent) of cells of maternal origin in certain tissues of mice aged between 4 and 60 days, which had developed in the uterus of a foster mother after transplantation at the blastocyst stage. Subsequently, they found maternal type cells in offspring from normal pregnancies.

The importance of these findings is obvious. One group has already been unable to confirm the results[3], and, using a slightly different experimental system, I have also produced no evidence for the porosity of the placenta to maternal cells.

Mice of the genotype W^vW^v have a genetically determined macrocytic anaemia, which may be permanently cured by the introduction of normal haemopoietic cells[4,5]. Using allogeneic tissue bearing the T_6 chromosome marker, I have found that whether the cells are injected in the neonatal period[6], or into adults previously made tolerant, or into adults under immunosuppression with antilymphocytic serum (M. J. S., manuscript in preparation) the outcome is always the same—the bone marrow rapidly becomes completely replaced by cells of donor origin. Further, the spleen, thymus and lymph nodes become largely composed (70–90 per cent) of the donor-type cells. It would thus appear that the injected normal cells have a definite selective advantage over the defective host cells.

These mice are also affected in foetal life—the defect being detectable by the twelfth day of gestation when yolk sac erythropoiesis is operative, and it continues through the phase of liver erythropoiesis[7]. It was felt therefore that these W^vW^v mice would make excellent subjects for a study of the porosity of the materno-foetal barrier to cells, for it was postulated that even if only a few maternal cells got across to the foetus, with such a selective advantage for genetically normal cells they would be able to proliferate and be detectable.

Because it was considered that the technique of introducing blastocysts into the uterus of a foster mother could possibly itself give rise to chimaerism, it was decided not to use this method, but to rely on normal pregnancies. Because the W^vW^v mice are sterile and anaemic, however, they must be derived from matings between the heterozygotes (genotype W^v+) which are fertile. These mice are also anaemic, but less severely so than the homozygotes. I have also found that these mice may be cured by the transplantation of genetically normal tissue[8], and although the bone marrow is not totally replaced, a very high degree of chimaerism results in this tissue (90 per cent) and in other organs of the lympho-myeloid complex.

The experimental system was as follows. Newborn W^v+ female mice were injected with around $8–10 \times 10^6$ haemopoietic cells, derived from the livers of 16–18 day old CBA-*T6T6* embryos. When these mice were at least 11 weeks old (it being known from previous work that the cells would have implanted and proliferated in a large number of individuals so treated), the success of the transplant was determined by a study of the haemoglobins in the peripheral erythrocytes. The CBA haemopoietic tissue produces a haemoglobin which, on electrophoresis on cellulose acetate paper at *p*H 8·6, yields a diffuse type of pattern. This is easily distinguishable from the single type of haemoglobin in the W mice. Those W^v+ mice which possessed a strong diffuse haemoglobin pattern, and which thus had a large proportion of chromosomally marked cells in their myeloid and lymphoid systems, were then mated with untreated W^v+ males. The resulting W^vW^v offspring (the other genotypes also produced by such a mating, W^v+ and $++$, being ignored,

Table 1. PERCENTAGE OF CBA-*T6T6* CELLS IN THE MITOSES OF THE TISSUES OF W^vW^v OFFSPRING DEVELOPED IN W^v+ MOTHERS TRANSPLANTED WITH CBA-*T6T6* HAEMOPOIETIC TISSUE

Age (weeks)	No. of mice	Per cent CBA-*T6T6* cells in the mitoses of Bone marrow	Spleen	Thymus	Lymph node
1	3	0	0	0	—
2	3	0	0	0	0*
3	3	0	0	0	0
4	3	0	0	0	0
6	2	0	0	0	0

One hundred cells were scored in each tissue.
* 1 mouse only examined.

on the grounds that they were considered to be less propitious hosts for the multiplication of the maternal cells) were allowed to develop normally after birth and were then killed at intervals for chromosome studies. The bone marrow, spleen, thymus and lymph nodes were studied in each of three mice at the age of 1, 2, 3 and 4 weeks and in two mice at 6 weeks. One hundred metaphase plates were scored in each tissue, but it was not possible to obtain enough cells to study the lymph nodes at the age of 1 week or at 2 weeks in two of the mice. The W^v+ mothers were killed shortly after their offspring had been examined in order that their chimaeric state could be quantitated. Chromosome preparations were made 1·5 h after the mice had been injected with 'Colcemid', by an air dry method[10], and stained with 2 per cent toluidine blue.

The results of the chromosome studies in the W^vW^v offspring are presented in Table 1. There were never any cells with the *T6* marker chromosomes in any of the tissues of the fourteen individuals studied, a total of 5,100 mitoses being examined in the series. Table 2 shows the percentage of CBA-*T6T6* cells among the mitoses of the maternal tissues: they were chimaeric to a considerable degree.

Table 2. PERCENTAGE OF CBA-*T6T6* CELLS IN THE MITOSES OF THE TISSUES OF W^v+FEMALES TRANSPLANTED WITH CBA-*T6T6* HAEMOPOIETIC TISSUE

No. of mice	Percentage CBA-*T6T6* cells in the mitoses of Bone marrow	Spleen	Thymus	Lymph node
7	91	79	91	53

Fifty cells were scored in each tissue.

Thus no evidence could be found for the porosity of the placenta to maternal cells. These findings differ therefore from those of Tuffrey *et al.*[1,2]. It is possible that the particular strain combination used by these workers endowed some especial facility for the passage of maternal cells across the placenta. Their experiments and mine examined the actual component cells of the myeloid and lymphoid organs of the offspring, the basic progenitor cell of which is the stem cell. Presumably therefore we were both investigating the passage of this type of maternal cell through the placenta. The whole myelo-lymphoid complex is not a static but a dynamic system, and the stem cells circulate freely within the blood and between the blood and the cellular compartments. It is on this basis that the use of W^v+ mothers so heavily populated with marker cells in this complex was justified for such a study of placental permeability.

I thank Miss A. R. Harcourt for technical assistance. This work was supported by the Spastics Society.

Lymphocyte Cytotoxic Antibodies in Systemic Lupus Erythematosus

WE have observed lymphocytotoxic antibodies in sera of patients with connective tissue disorders. The antibodies are cytotoxic to lymphocytes from unrelated random donors using the microcytotoxicity technique[1,2]. The initial studies were done on 161 coded stored sera submitted to the clinical laboratory for routine immunoelectrophoresis, and confirmatory studies were done on forty-seven coded sera selected from patients followed in the clinic for connective tissue disorders. Results of testing of both series of sera are summarized in Table 1 and show that 74 per cent of all sera tested from patients with systemic lupus erythematosus and 14 per cent of sera from patients with rheumatoid arthritis contained lymphocytotoxic reactivity. Appropriate controls indicated that the cytotoxic effect of lupus sera was dependent on complement; fractionation of one lupus serum by anion exchange chromatography indicated that the cytotoxic factor resides among the IgG globulins. Because cytotoxic antibodies are not present in sera of normal persons except in some cases of immunization by multiple transfusions[3,4], pregnancy[5,6] or organ transplantation[7,8], the results suggest that lymphocytotoxic antibodies develop during the course of systemic lupus erythematosus.

Table 1. INCIDENCE OF LYMPHOCYTOTOXIC ANTIBODIES IN SERA OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND RHEUMATOID ARTHRITIS

Disease	Study	Number of patients: Total tested	Number of patients: Cytotoxic antibodies present	No. of sera: Total tested	No. of sera: Cytotoxic antibodies present
Systemic lupus erythematosus	Series 1	12	9 (75%)	18*	11 (61%)
	Series 2	24	19 (79%)	40	32 (80%)
	Total	36	28 (78%)	58	43† (74%)
Rheumatoid arthritis	Series 1	21	3 (14%)	21*	3 (14%)
	Series 2	7	1 (14%)	7	1 (14%)
	Total	28	4 (14%)	28	4† (14%)

* In series 1, the 122 remaining sera from patients with other diseases were also examined, of which seventeen (14 per cent) had cytotoxic activity. Positive reactions were seen in three patients with pulmonary fibrosis and one with myasthenia gravis. No clinical data were available on the remaining thirteen cytotoxic sera.

† The forty-seven lymphocytotoxic sera reacted with lymphocytes from varied numbers of donors. Twenty reacted with lymphocytes from 2 to 24 per cent, 14 with 25 to 49 per cent, and 13 with 50 to 100 per cent of the donors.

Readings in the microcytotoxicity tests were scored on the basis of the percentage increase in number of dead cells compared with negative controls: 0–9 per cent, negative (−); 10–14 per cent, doubtful (±); 15–24 per cent, weakly positive (+); 25–84 per cent, positive (+ +); 85–100 per cent, strongly positive (+ + +). Only the + + and + + + reactions were used in the calculations for this table.

Coefficient of correlation[9] (*r*) values were obtained between fifty-four sera of known HL-A specificity and the thirty-seven cytotoxic sera in series 2 which included the thirty-three strongly cytotoxic sera (Table 1) and in addition four other sera which showed only a weakly positive reaction. Reactions of two of the lupus sera correlated with sera of known HL-A specificity (Table 2). Reactions of thirty-three of the thirty-seven sera tested correlated inversely with those of HL-A specific sera. When these thirty-three sera from lupus and rheumatoid patients were compared among themselves, their reactions were divisible into three or more groups, suggesting that they may recognize three or more lymphocytic antigens distinct from the ten known HL-A antigens. It is possible that certain components of the lymphocyte cell membrane become antigenic as a result of yet unknown pathological processes in systemic lupus erythematosus. The individual may then form antibodies to these antigens which, in the presence of complement, cause the lymphocytes to lyse and release intracellular contents. Further studies are required to determine the importance of such a mechanism in the pathogenesis of the disease.

This study was supported by grants from the US National Institutes of Health to the General Clinical Research Center, the Cardiovascular Research and Training Center, and the Arthritis Training Program, the

Table 2. EVALUATION FOR HL-A SPECIFICITIES IN THIRTY-FIVE LYMPHOCYTOTOXIC SERA FROM PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND RHEUMATOID ARTHRITIS

Coefficient of correlation (r)*	Antigen groups of known antisera									
	HL-A1	HL-A2	HL-A3	HL-A9	HL-A5	HL-A7	HL-A8	Da4	4a	4b
Positive sera ($r \geq 0{\cdot}3$)	0	1	0	0	1†	1†	0	0	1†	0
Negative sera ($r \leq 0{\cdot}1$)	18	7	7	14	15	2	6	8	10	0

*r value considered only when correlation appeared with more than one antiserum of known HL-A specificity.

† Single serum showing these positive correlations.

The forty-seven sera of series 2 were examined with a panel of the same forty-three cells from unrelated random healthy donors: thirty-three were clearly positive (+ +, + + +) and four were weakly positive (+). The cytotoxicity reactions of these thirty-seven sera were compared with those of fifty-four antisera containing specificities for known histocompatibility antigens. Two of the thirty-seven sera reacted with lymphocytes from all donors and therefore gave no correlation. Entries in this table are based on the remaining thirty-five sera. Any one antigenic group was present on lymphocytes from a minimum of five and a maximum of thirty-nine of the donors.

Delayed Hypersensitivity in *Trypanosoma cruzi* Infection

THE *in vitro* method of studying delayed type hypersensitivity has never been applied to protozoal infections. This communication presents evidence that delayed type hypersensitivity can be demonstrated *in vitro* in mice immunized against *Trypanosoma cruzi*, the causative microorganism of Chagas' disease, and in mice infected with *T. cruzi*.

Delayed type hypersensitivity occurs in all intracellular infectious diseases[1]. Until recent years this phenomenon could be studied only *in vivo* state with skin tests. The development of a positive skin test of the delayed type is shown to be associated with the acquisition of cellular immunity by the animal[2,3]. In fact, these two terms are used interchangeably by many workers. *In vitro* methods of studying delayed type hypersensitivity have recently been introduced, and these methods have been applied to study this phenomenon in bacterial infections, principally infections by *Mycobacterium tuberculosis*, *Brucella*, *Streptococcus*, *Listeria monocytogenes*, and some fungal and viral infections. In protozoal diseases, skin tests of the delayed type are available for infections by *Leishmania*, *Trichomonas*, *Toxoplasma* and *Trypanosoma cruzi*[4,5].

Rich and Lewis first described *in vitro* migration of cells from spleen cell explant as an index of delayed type hypersensitivity[6]. George and Vaughan, and David *et al.*, modified and improved this test and put it on a semi-quantitative basis[7,8]. Recently Fauve and Dekaris described a simpler test, the macrophage spreading inhibition on glass surface[9]. It has also been shown that the degree of inhibition of macrophage spreading correlates well with the long established *in vivo* skin test for delayed type hypersensitivity[10].

Peritoneal washing was obtained from four groups of Carworth Farm Strain 1 (CF1) male mice of body weight 25–30 g. Group *A* were normal CF1 mice. Group *B* were mice given 10^6 cultural form *Trypanosoma cruzi*. The cultural flagellates gave rise to low grade and transient parasitaemia, and the mice developed premunition against future virulent challenge. Group *C* were immunized by subcutaneous injection of 5·0 mg of desiccated cultural *T. cruzi* incorporated in Freund's complete adjuvant (0·1 ml. of *T. cruzi* antigen in saline homogenized with 0·1 ml. of adjuvant for each mouse). Peritoneal washing was obtained from groups *B* and *C* 2 months after the inoculation. Group *D* were immunized as group *C*, but 1 month after the immunization the mice of group *D* were challenged with virulent mouse blood form of Peru strain *T. cruzi*. Peritoneal washings were obtained from the survivors 2 months after the challenge.

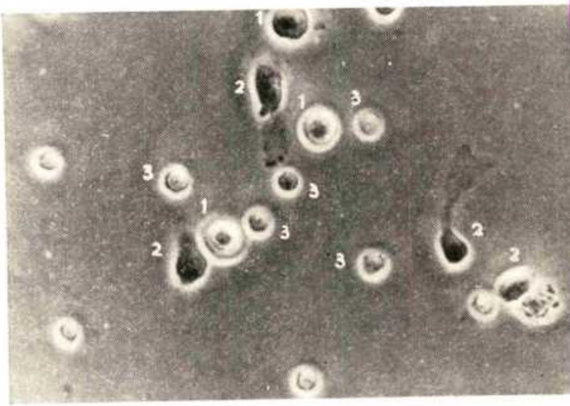

Fig. 1. Phase contrast photomicrograph of peritoneal cells after incubation for 30 min at 37° C. 1, Macrophages; 2, spreading macrophages; 3, lymphocytes.

The mice were exsanguinated by decapitation and the abdominal wall was opened and fur stripped back. Three ml. of tissue culture medium 199, with 5 units of heparin and 20 mg of bovine serum albumin per ml. added, were injected into the abdominal cavity along the mid-line. The abdomen was gently rocked to distribute the fluid throughout. The fluid was then withdrawn. Care was taken to avoid traumatic bleeding. This abdominal washing has an average cell count of 2×10^6 cells/ml. The proportion of lymphocytes and macrophages varies from 2 : 1 to 1 : 2. This is true in all groups of mice studied.

The macrophage spreading inhibition was determined by the method of Fauve and Dekaris[9]. The peritoneal washing was gently shaken and 1 ml. was put into each of two polyethylene tubes. To one tube was added 0·05 ml. of a saline extract of cultural form *T. cruzi* antigen (equivalent to 0·05 mg of lyophilized *T. cruzi*), and to the other was added 0·05 ml. of isotonic saline. After gentle shaking, the tubes were incubated in a water bath at 37° C for 30 min. After the incubation the tubes were gently shaken and a drop was put into a Thoma counting chamber. This was then incubated for another 30 min in a

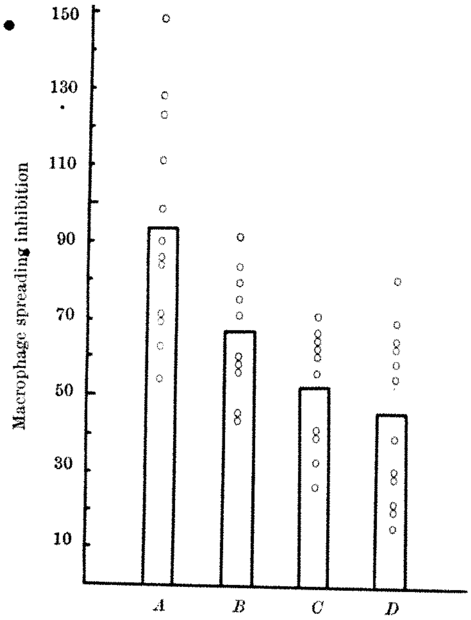

Fig. 2. Macrophage spreading inhibition of mouse peritoneal cells by *Trypanosoma cruzi* antigen. *A*, Normal mice; *B*, acute *T. cruzi* infection; *C*, immunized with lyophilized *T. cruzi* in Freund's complete adjuvant; *D*, immunized as in *C* and recovered from virulent challenge.

moist chamber at 37° C. A reading was taken with phase contrast microscopy using a Leitz Ortholux microscope with ×500 magnification. The cells in all four corner squares (white cell count chambers, each square having a volume of 1 mm^3) were counted and the number of cells that had spread was noted. The macrophages are larger and darker than the lymphocytes. Only the macrophages with spreading cytoplasm and irregular borders are considered to have spread. The photomicrograph (Fig. 1) shows the typical appearance of the spreading macrophages. The percentage of spreading cells varies from animal to animal, but it is usually in the neighbourhood of 20–40 per cent. Readings in duplicate preparations from the same mouse usually agree closely. The macrophage spreading inhibition is calculated from the following formula

$$\text{MSI} = \frac{\text{Average per cent spreading with antigen}}{\text{Average per cent spreading without antigen}} \times 100$$

Fig. 2 shows the results obtained in the different groups of mice. Each point represents the result from one mouse. It can be seen that there is a great variation of the MSI in each group. The horizontal bars represent the means of the groups. It can be seen that, compared with the normal group of mice (group *A*), there was significantly more inhibition of macrophage spreading in the presence of *T. cruzi* antigen in the acutely infected group (group *B*), the group immunized with killed *T. cruzi* incorporated in Freund's complete adjuvant (group *C*), and the similarly immunized group that had subsequently survived the virulent challenge (group *D*) (with 't' test $P<0{\cdot}05$, $P<0{\cdot}001$ and $P<0{\cdot}001$ respectively). The difference between groups *B* and *C* was minor and at the borderline of significance ($P=0{\cdot}05$). Groups *C* and *D* showed no significant difference in MSI in the presence of *T. cruzi* antigen. Not shown in the figure are the group of mice given Freund's complete adjuvant alone without *T. cruzi* antigen. The MSI of this group (mean MSI = 85) was not significantly different from the non-vaccinated and non-infected mice.

This work was supported by a fellowship from the Medical Research Council of Canada. I thank Professor A. W. Woodruff and Dr P. D. Marsden for providing the laboratory facilities.

Ion Dependent Conductance: Switching in Lipid Bilayers

The action of antibiotics on the ionic conductances of lipid bilayers has provided useful models of permeation mechanisms in biological membranes[1,2]. Voltage dependent conductance states are of special interest. They have been demonstrated for nerve[3] and are probably present, though with much slower kinetics, in other cell types[4,5]. There is a distinction between ion selective conductances and ion dependent switching of conductances which themselves may or may not be selective. For example, one has the well known effect of $[Ca^{2+}]$ on the Na^+ conductance[6] in nerve, and more recently $[K^+]$ has been shown to increase the inactivation parameter and time constant of this conductance[7]. I wish to describe two examples of the effect of $[Na^+]$ favouring a low conductance state even though the voltage dependence is opposite in each case and there is no ion selectivity for the conductances.

Fig. 1*A* shows a continuous record of the voltage–current relationship for phospholipid and equimolar phospholipid–cholesterol bilayers in the presence of the cyclic hexadepsipeptide, monamycin[8], after a steady state of incorporation has been reached. It reveals an asymmetry arising from the presence of Na^+ on one side and K^+ on the other in the sense that an Na^+ current causes a switch to a lower conductance state, from which the time constant for the recovery is approximately 10 s. For the phospholipid bilayer there is no ion selectivity for either the high or low conductivity; the almost vanishing zero-current potential is evidence for this. For the phospholipid–cholesterol bilayer, however, there is a substantial K^+ selectivity for the low conductance state which may be connected with the greater ratio of high to low conductances.

Fig. 1*B* shows the behaviour of the phospholipid bilayer in the presence of the cyclic nonadecapeptide, alamethicin, in the same conditions. Here, as has been reported for symmetrical NaCl solutions[9], there is a switch to a high conductance, the increment for an *e*-fold increase being 4·5 mV. In this case, however, the potential for a measurable conductance is shifted by at least 25 mV, or a factor 250 times, in favour of the K^+ current. In spite of this the bionic (zero current) potential is negligible (about −8 mV). The results for phospholipid–cholesterol are not significantly different.

For both antibiotics the apparent order *n*, of what is presumably a surface association, is high as judged by concentration dependence. For alamethicin[9] $n=6$; for monamycin one can estimate that it is the same by fitting

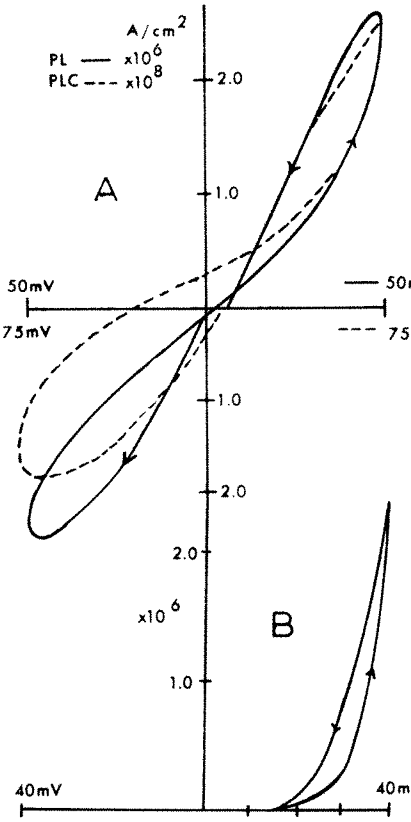

Fig. 1. Continuous voltage-current recording with voltage sweep frequency $f = 0{\cdot}06$ s^{-1}, 10 mM potassium and sodium phosphate buffer at pH 7·3 inside and outside respectively; positive current outwards. PL, phosphatidyl choline (from soya bean) 30 mg/ml. in 1 : 2 dodecane–octane; PLC, 20 mg cholesterol and 10 mg phosphatidyl choline in the same solution. *A*, 3×10^{-8} M monamycin both sides; *B*, 7×10^{-7} M alamethicin both sides.

the sigmoid kinetics of the low potential conductance to $(1 - e^{-kt})^n$; that is, a rate-limiting first order reaction followed by an nth order reaction which leaves an excess of reactants. A forward rate constant $k_1^+ \sim 0{\cdot}01$ s^{-1} for symmetrical K$^+$ solutions, and at least an order of magnitude smaller for symmetrical Na$^+$ solutions is then found. In the case of alamethicin and possibly also monamycin, k_1^+ is also voltage dependent (but in an opposite sense). This scheme of kinetics is formally the same as the Hodgkin–Huxley[3] phenomenological description of the K$^+$ channel in nerve. The analogy is further reinforced by the fact that adding 1 mM teraethylammonium to one side of symmetrical K$^+$ solutions, one can induce asymmetry similar to that observed in Fig. 1*A*. Because tetraethylammonium is quite impermeant in these conditions (judged by the large bionic potential against K$^+$ alone), this is a surface reaction and does not involve ionic current *per se*.

Although the tertiary structure of the above peptides is not yet known, similar results have been found for gramicidin *S* whose structure is completely known[10]. In each case there is a specific structural effect of cholesterol which seems to act on the equilibrium constant of the nth order reaction. When more of these structures are known it should be possible to elucidate this effect.

The biological significance of these results is that one has a control mechanism which, because it is non-linear with respect to potential, is somewhat more flexible than simply changing the ionic selectivity of conductance. Elsewhere I have shown that the latter effect occurs with the cyclic decapeptide, tyrocidine *B*, in the presence of amines (unpublished results of M. C. G.). That amines have this effect in these systems suggests that they can be models for the membrane mediated action of biogenic amines.

I thank Professor C. H. Hassall, University College of Swansea, for monamycin and Dr George B. Whitfield, Upjohn Company, for the alamethicin.

Strychnine, Glycine and Vertebrate Postsynaptic Inhibition

ON the basis of experiments performed on Mauthner cells of the goldfish, the suggestion has been made[1] that the competitive and reversible antagonism demonstrated in the feline spinal cord between glycine and strychnine[2–4], an alkaloid known to block spinal postsynaptic inhibition, does not necessarily support the proposal that glycine could be a spinal inhibitory transmitter in the cat.

In the goldfish, strychnine administered systemically in amounts adequate to suppress the late collateral inhibition of Mauthner cells has little or no effect on the inhibitory action of electrophoretically administered glycine[1]. In the cat the effect of glycine on spinal motoneurones and Renshaw cells has also been reported to be more resistant to antagonism by intravenously injected strychnine than the synaptically released transmitter[2–4], and an explanation has been offered for this in terms of the distribution of receptors activated by glycine. Inhibitory postsynaptic potentials are generated by the summed activity at a number of synapses distributed over the soma-dendritic membrane of the neurone. On the other hand, the hyperpolarization induced by electrophoretically administered glycine probably results from the more intense activation of a smaller area of the postsynaptic membrane. Thus, assuming glycine to be the transmitter, the concentration of this amino-acid in this region of the membrane is presumably much higher than that at the synapses generating an equivalent synaptic hyperpolarization. As a consequence, concentrations of a systemically injected glycine antagonist adequate to block the synaptic response could have minimal or no effect upon the action of locally administered glycine. As in the cat[2–4], elevation of the strychnine concentration in goldfish beyond that which blocks synaptic inhibition does result in a reduction of the effectiveness of glycine[1].

By contrast with these results, when administered electrophoretically from micropipette adjacent to that ejecting glycine, strychnine readily blocks the action of glycine on feline spinal neurones; it is, however, relatively ineffective as an antagonist of postsynaptic inhibition[2–4], as might be expected if the alkaloid fails to gain access to membrane sites located remotely from the micropipette. Similar arguments have been proposed to explain differences in the effectiveness of systemically and electrophoretically administered dihydro-β-erythroidine as an antagonist of acetylcholine, released electrophoretically or from axon collateral terminals, upon feline Renshaw cells[5].

It is thus possible that the apparent low sensitivity to systemic strychnine of the inhibition of Mauthner cells by glycine arises also from differences in local concentrations of glycine which achieve similar degrees of inhibition after electrophoretic or synaptic release. If this is so, the results obtained in the goldfish[1] provide no evidence for a presynaptic action of strychnine, and support a transmitter role of glycine, or a "glycine-like" amino-acid[2-4], at vertebrate strychnine-sensitive inhibitory synapses.

Strychnine Antagonism and Glycine: a Reply

Drs Curtis and Johnston seem to have overlooked certain items in our experiments. The important question is, should one expect the concentration of strychnine which blocks the action of a synaptically released transmitter to cause a reduction in the action of the same substance delivered iontophoretically to the neurone? Our critics quote experiments in which they measured the inhibitory hyperpolarization, which is of course a function of the driving force on the ions, as well as the change in membrane resistance. In our experiments these facts must be stressed: (*a*) The physiological response we measured, the increased membrane conductance (a direct measure of transmitter action), was largely the result of synaptic action on the region of the cell from which we recorded, and the glycine was pipetted onto the same region of the cell (and indeed must sometimes have reached even more distant regions also). The contribution to our recorded conductance changes of physiological inhibitory activity more than about 200 μm along the dendrites would be small. We did not detail the evidence for these items, but simply quoted the work on which they are based[1]. (*b*) The strychnine concentration about the cell, as detected by the blocking of physiological inhibition, rose gradually until the effects of two independently activated inputs were totally prevented (we would have detected an inhibition as little as 2 per cent of the control). (*c*) At this critical blocking concentration of strychnine, glycine effects were unchanged over a range of doses from the just detectable to the obviously "saturating" (not only doses "which achieve similar degrees of inhibition after electrophoretic or synaptic release"). The smallest glycine dose whose effect we could reliably measure caused a 1–2 per cent inhibitory conductance change; this was less than 1/20 of that caused by a "saturating" dose. These small responses to glycine should be compared with the relatively enormous conductance change during synaptic activation (50–60 per cent increase). It is difficult to imagine that this threshold glycine dose was causing a "more intense activation of a smaller area of the postsynaptic membrane" than that involved in the full physiological response. Nevertheless, the direct effects of this small dose of glycine (and of the larger doses) were quantitatively unaffected, even though the very large physiological response was not just reduced but totally eliminated.

The point we wish to make is that experiments which attempt to answer the questions we asked are necessary in order to exclude the possibilities raised in our report. If the blocking action of strychnine is to be used as evidence, then the investigation must be made quantitatively, with regard to the critical concentration of strychnine, the dose-response relations of glycine, and the extent of cell activated both physiologically and pharmacologically. It is important to note the results of the analogous experiment performed at the neuromuscular junction: curare, in uniform concentration over the preparation, was somewhat more effective in reducing the end-plate potential than in reducing the iontophoretically applied acetylcholine potential, but the effects of small doses of acetylcholine seemed to be readily abolished[2]. These findings further strengthen our concern about accepting the qualitative observation that strychnine blocks both physiological and pharmacological inhibition as evidence for the identification of the transmitter. Our results still leave the possibility that a glycine-like substance (or perhaps a glycine complex) is a transmitter. But the postsynaptic action of strychnine, as revealed by glycine itself, seems to require larger concentrations of strychnine than are necessary to block the effects of physiological inhibition (at least on the Mauthner cell).

5-Hydroxyindoleacetic Acid Levels in the Cerebrospinal Fluid of Depressive Patients treated with Probenecid

ACCORDING to the serotonin (5-hydroxytryptamine, 5-HT) hypothesis there is a causal relationship between mental depression and 5-HT deficiency in the brain[1-3]. Some depressive patients—mainly those suffering from an endogenous depression—display the following clinical signs. (1) The concentration of 5-hydroxyindoleacetic acid (5-HIAA) in the cerebrospinal fluid (CSF) (refs. 4 and 5) and the urinary concentrations of 5-HT (ref. 6) and 5-HIAA (refs. 7 and 8) are unusually low. (2) The transformation of 5-hydroxytryptophan into 5-HT seems to be defective[9] (although in a later publication Coppen[1] reported his inability to reproduce these findings). (3) Precursors of 5-HT which readily enter the brain—5-hydroxytryptophan[10] and tryptophan[11]—can have a therapeutic effect. Finally, in suicide victims the cerebral concentration of indoleamines proved to differ from that in a control group and, according to Shaw *et al.*[12], the 5-HT concentrations were diminished. Bourne *et al.*[13] were unable to corroborate this but did find a diminished concentration of 5-HIAA.

These data pertain to absolute concentrations and offer insufficient information on the rate of metabolism of 5-HT. It is evident that suitable methods for the calculation of the turnover of 5-HT in the human brain are required before the serotonin hypothesis can be established. Neff *et al.*[14] have found, in rats, that the transport of 5-HIAA from the brain into the bloodstream is almost totally inhibited by *p*-(dipropylsulphamoyl)benzoic acid (probenecid). They also suggested that the rate of accumulation of 5-HIAA under the influence of probenecid could be equated with the rate of synthesis of 5-HT in the brain. In dogs, the concentration of 5-HIAA in the CSF increased following probenecid administration[15]. There are indications (albeit indirect) that acid amine metabolites in CSF are derived from brain amines and that changes in the CSF acid concentrations may reflect the metabolism of the cerebral amine precursor[16,17]. If this is true, then the rate of increase of the 5-HIAA concentration in the CSF under the influence of probenecid can be regarded as an index of the rate of synthesis of 5-HT in the brain.

Olsson and Roos[18] were the first to apply the probenecid test to human subjects: sufferers from Parkinson's disease. The purpose of our study was to establish whether the effect of probenecid in depressive patients supplies evidence of a reduced synthesis of 5-HT in the brain. We treated fourteen patients with "vital" (or "endogenous") depressions and eleven non-depressive controls. The diagnosis was established on the basis of the results of a structured standard interview[19]. The examination was performed between the fifth and the tenth days after arrival at the hospital. All test subjects had been without medication for at least a week. Age and sex distribution in the two groups were not significantly different.

The test was as follows (personal communication from B.-E. Roos). On the first day, a lumbar puncture was made between 0900 and 1000 h. On the second and third days, $4 \times 0·5$ g probenecid was given orally; a further 1 g probenecid was given on the fourth day, at 0730 h, followed 4 h later by the second lumbar puncture. The CSF was stored at $-20°$ C and the 5-HIAA concentration was determined by the method of Korf[20] within three days of collection. In the procedure described, the probenecid test merely gives an impression of the rate of accumulation of 5-HIAA. More exact determination requires that more than two points of the 5-HIAA rise curve are known; this, however, would require as many lumbar punctures, which was not considered justifiable.

In the vital depression group, the mean 5-HIAA concentration in the CSF before administration of probenecid was significantly lower than in the control group ($P < 0·01$, Wilcoxon test), which corroborates the observations of Ashcroft *et al.*[4] (Table 1). After probenecid administration the concentration of 5-HIAA in the CSF rose in all subjects in both groups. The mean rise in the control group corresponds with the values found by Olsson and Roos[18] (Table 1). The rise in the vital depression group was smaller than that in the control group ($P = 0·05$, Wilcoxon test), which argues in favour of the 5-HT hypothesis provided that: (1) the rates of synthesis of 5-HIAA and of 5-HT are in fact identical, and (2) probenecid absorption was the same in all test subjects. The possibility that low probenecid absorption in the intestine is the cause of a small effect of probenecid is now being investigated by carrying out a parenteral probenecid test as well in these cases.

Table 1. CONCENTRATION OF HIAA IN THE CSF IN DEPRESSIVE PATIENTS AND CONTROLS BEFORE AND AFTER PROBENECID ADMINISTRATION

Group	No. of test subjects	5-HIAA concentration in CSF (μg/ml.) Before probenecid	After probenecid	Difference
Vital depression	14	0·017 ± 0·017 (0·000 – 0·046)	0·039 ± 0·025 (0·030 – 0·067)	0·022 ± 0·020 (0·000 – 0·073)
Control	11	0·040 ± 0·024 (0·004 – 0·081)	0·074 ± 0·026 (0·021 – 0·098)	0·035 ± 0·018 (0·017 – 0·060)

Results are given as means ± *S.D.* (with range).

The vital depression group included seven patients whose 5-HIAA concentration in the CSF rose by less than 0·020 μg/ml. after probenecid administration; the control group included only one such case. The difference was statistically significant ($P < 0·05$, Fisher's exact probability test). Vital depressive patients with a normal and those with a subnormal probenecid effect were indistinguishable in terms of psychopathological manifestations. In particular there was no correlation with the patient's motor inhibition or agitation.

The significance of the wide variation of chemical parameters in psychiatric patients is not generally appreciated. We believe that vital depressive patients with a subnormal probenecid effect may be incidental variants of the normal, but they can equally well constitute a group *sui generis*. Assuming that the latter is the case, and that mood and 5-HT metabolism do correlate, we conclude that 5-HT deficiency plays a part in some vital depressions but not in others. The group of vital depressions, which tends to be homogeneous in psychopathological terms, is therefore heterogeneous in terms of pathogenesis[21].

Abnormal Zygote Development in Mice after Paternal Exposure to a Chemical Mutagen

AFTER paternal exposure to mutagens and subsequent mating, adverse genetic effects are seen in the form of pre-implantation losses of fertilized ova and zygotes, early foetal deaths, and sterility and semi-sterility in F_1 progeny[1]. Early foetal deaths are a direct quantitative index of dominant lethal mutations. These are generally concomitant with pre-implantation losses, which thus constitute a presumptive but less specific measure of mutagenicity[1]. A practical, sensitive assay for mutagens, based on the induction of dominant lethal mutations in mammals, has been developed and applied to a wide range of environmental chemical pollutants and to drugs[2].

The development of mammalian zygotes is retarded, as a result of induced mutations and chromosome anomalies, after paternal irradiation[3-8], artificial insemination with spermatozoa treated *in vitro* with chemical mutagens[9], and paternal[10] or maternal[11] treatment with chemical mutagens. We report here quantitative data on fertilization and the development of zygotes in mice after paternal exposure to a chemical mutagen and subsequent mating during the entire spermatogenic cycle.

Random-bred ICR/Ha Swiss male mice, 8–10 weeks old, were injected intraperitoneally with single doses of 10 mg/kg of triethylenephosphoramide (TEPA) in 0·1 ml. of aqueous solution; untreated males served as concurrent controls. Each male was then caged for 1 week with three virgin females, 8–10 weeks old, after which females were replaced weekly and consecutively with fresh animals for a total of 8 weeks. Matings in weeks 1–3 and 4–8 after injection represent samplings of sperm exposed to TEPA in

Table 1. INCIDENCE OF RETARDED AND/OR MALFORMED OVA AFTER MATING WITH MALE MICE TREATED WITH TEPA

* Most of these ova were retarded by only one cleavage stage. If these are considered as normally developed, then the percentage of cleaved ova which are normal in all respects would be increased from 48 to 84 per cent.

post-meiotic and pre-meiotic phases of spermatogenesis respectively. Females were killed after detection of vaginal plugs to obtain ova at the stage of 10, 30, 60 and 82 h post-ovulation (±2). Six replicates, with concurrent controls, were studied to yield a range of eight to seventeen females at each stage of zygote development for each mating week. Tubal ova and blastocysts were collected by flushing oviducts and uterine cornua respectively with 2 per cent sodium citrate; recovered ova were fixed overnight with 10 per cent buffered formalin, and stained with 1 per cent lacmoid[12]. Ova were scored as fertilized if the spermatozoon or its tail was found in the vitellus, or if the second polar body was present. Zygotes were scored for numbers of blastomeres, morphological anomalies such as alterations in relative blastomere size, micronuclei and multinucleate blastomeres.

The following data relate to all mating weeks other than the sixth, which are presented separately. At 10 h, the overall incidence of fertilized ova, for all weeks of mating other than the sixth, was 97 per cent for both test and control mice. By 30 h, 98 and 100 per cent of fertilized ova in test and controls respectively had undergone first cleavage (Fig. 1). In ova at the two cell stage, taken from test animals in the first, second and third mating weeks, there were 72, 50 and 20 per cent of micronuclei respectively; in ova from females mated during weeks 4 to 8 after males had been treated with TEPA, and in control matings at all times, there were < 1 per cent micronuclei. Sixty and eighty-two hours after ovulation, retardation of cleavage and other abnormalities were evident in test zygotes (Table 1 and Fig. 1). Retarded zygotes comprised 40, 56 and 26 per cent of cleaved ova 60 h after ovulation from matings in the first, second and third weeks respectively; corresponding values after 82 h were 70, 40 and 18 per cent. More than 90 per cent of retarded ova had other anomalies, such as anisocytosis, and multinucleate blastomeres. Such anomalies were also seen at 82 h in unretarded test zygotes—84, 82 and 38 per cent, in matings from weeks 1, 2 and 3 respectively.

The incidence of fertilized ova from the sixth mating week was markedly reduced—42, 48, 45 and 57 per cent at 10 h, 30 h, 60 h and 82 h respectively (Table 1). Most of these were at the two cell stage by 30 h. By 60 h, about half the zygotes consisted of four cells, revealing a delay of one cleavage stage. But this slight retardation was no longer apparent by 82 h. No other morphological anomalies were observed at this mating period.

The biphasic effects of TEPA on epididymal spermatozoa and spermatids, and on spermatogonia, denote different mechanisms. With post-meiotic matings, fertilization apparently proceeds normally and is followed by retarded and abnormal development of zygotes. Spermatogonial effects induced by TEPA seem to be largely restricted to a marked reduction in fertilization; such infertility is probably a consequence of aspermia[13]. These effects, however, also have a genetic component, for they are associated with pre-meiotic and post-implantation zygote deaths[1].

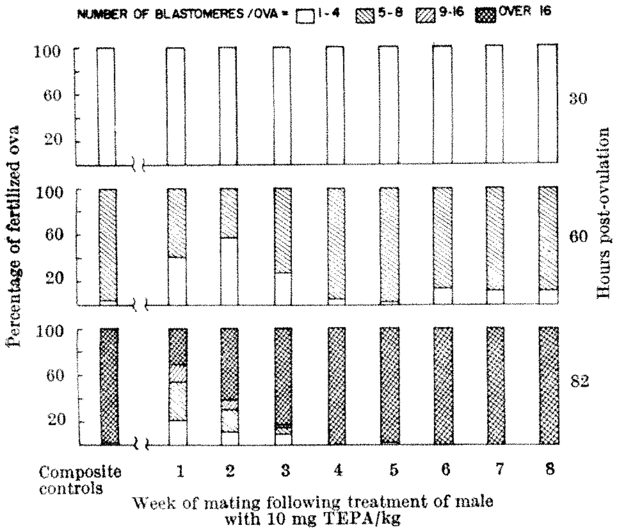

Fig. 1. Early embryonic development of fertilized ova in females mated with control males and males treated with TEPA.

Effects of Hallucinogenic and other Drugs on the Nest-building Behaviour of Mice

WE have found that nest-building is ideally suited for the study of the effects of hallucinogenic drugs. Strains of laboratory mice differ in their nest-building activity. Males of the C57Bl/6j strain (Jackson Laboratory, Bar Harbor, Maine) are very reliable in daily testing and consequently well suited for experiment. Briefly, testing involves removal of the existing nest and provision of material for a new one. After a few days of adaptation to this procedure the mouse retrieves the material and builds the new nest within a few minutes after provision of the fresh material.

There are three primary components in nest-building: (*a*) retrieval of the nest material, (*b*) shredding behaviour (dismantling of the cotton dental balls), and (*c*) working the material together to form a single unit. We found that this sequence takes only 7 min, and the nest is in its final form within 45 min. Although nest-building may seem to be a cooperative endeavour in groups, our observations suggest that at least retrieval is competitive. In general, the pattern of behaviour is the same for isolated animals except for the occasional animal that may shred some of the cotton before retrieval. If animals are tested during their sleep period, they may only retrieve the material to make a mat, and the shredding and final shaping of the nest may not occur until the high activity period.

The drugs tested were chlorpromazine, chlordiazepoxide, desipramine, mescaline, 2,5-dimethoxy-4-methyl amphetamine (DOM), 2,5-dimethoxy-4-ethyl amphetamine (DOET), 3,4,5-trimethoxy amphetamine (TMA), D-amphetamine and LSD_{25}. Animals were placed individually in 26×35 cm wooden boxes with a wire floor at least 3 days before receiving nesting material, to allow for exploration and choice of a sleeping corner, which usually became the nest site. Twenty animals, 60 days old at the beginning of treatment, received a wide range of doses of each drug. All injections were of 0·1 ml., administered intraperitoneally at intervals of at least 4 days. Each animal served as its own control, receiving saline injections at the beginning and the end of each set of drug treatments.

On a test day, an animal was injected with drug or saline, returned to its box, and the old nest was removed. Thirty minutes after injection, forty tightly packed fresh dental balls, 6 mm in diameter, were placed randomly on the floor of the box and we recorded the behavioural pattern, state of activity relating to retrieval, shredding, time required to complete retrieval, number of cotton balls retrieved and the quality of the completed nest. Twenty-four hours after administration of the drug, animals were tested without injection to determine whether recovery from the drug was complete.

There was no readily observable effect of chlorpromazine, chlordiazepoxide and desipramine on the primary components of nest-building except in doses which obviously impaired motor activity. In these cases there was only partial retrieval of the cotton balls, or the behaviour was completely inhibited, presumably until the effects of the drug had subsided.

Mescaline and the amphetamine compounds with known hallucinogenic properties, however, produced considerable changes in behaviour. Effects were most pronounced during the retrieval phase. All drugs induced a stereotyped behavioural pattern that competed with and disrupted the normal pattern. The duration of the competing behavioural pattern was dependent on the dose and type of drug and was typically followed by a period of inactivity before the onset of the normal retrieval pattern. Descriptions of the various induced behavioural characteristics observed during the time that retrieval of the material to the nest site would have occurred normally are presented in Table 1. A drug is not included in the matrix unless the behavioural characteristic was observed in at least 50 per cent of the animals.

Table 1. QUALITATIVE ANALYSIS OF THE DRUG EFFECTS AFTER INITIAL PRESENTATION OF NESTING MATERIAL

	Dose in mg/kg								
	0·25	0·50	1·0	2·0	4·0	8·0	10·0	20·0	25·0
Actively avoids cotton, runs between or jumps over			AMPH	AMPH	AMPH				
Shreds intensively						AMPH*			
Explores cotton with minimal handling		DOET	DOET	DOET					
Explores cotton vigorously, repeated stereotypic manipulation of dental balls	DOM	DOM	DOM	DOM*	DOET*	TMA	TMA* MESC	MESC	
Paroxysms of ear and neck scratching		DOET	DOET	DOET DOM*	DOET*		TMA*	MESC	MESC*
Mild tremors				DOM*	DOET*	AMPH*			MESC*
Inhibition of retrieval of nest material	DOET DOM	DOET DOM AMPH	DOET DOM AMPH	DOET DOM* AMPH	DOET* AMPH	TMA AMPH*	TMA* MESC	MESC	MESC*

* Maximum dose used.

DOM, TMA and mescaline produced the same behavioural profile with a potency relationship similar to that reported for humans[1]. DOET and D-amphetamine induced behavioural patterns unique to each drug and easily differentiated from the effects produced by the other drugs. Four mg/kg of DOET had an effect similar to that of DOM, however. Likewise, the behaviour induced by 8 mg/kg of D-amphetamine changed from apparent avoidance of the cotton to intensive fine shredding.

We found that the animals were shredding the tightly packed dental balls a single strand at a time. Avoidance of the dental cotton balls after injection with D-amphetamine is not merely the result of increased activity. All drugs used increase activity, without the same end result. Furthermore, other experiments with morphine, resulting in high activity, did not induce active avoidance of the

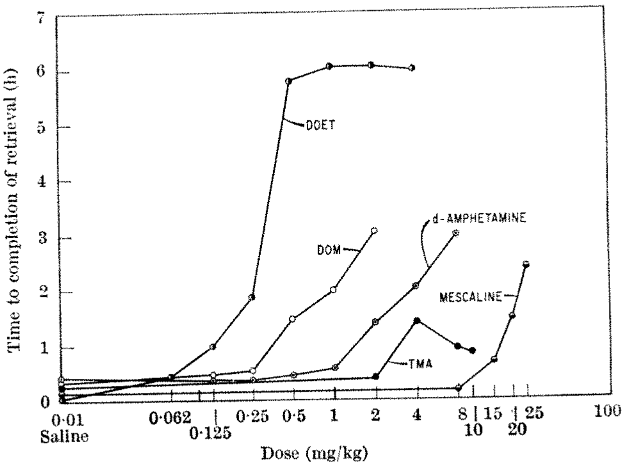

Fig. 1. Curves showing the time passed before retrieval of cotton to the nest site. Each curve is based on the mean of twenty animals.

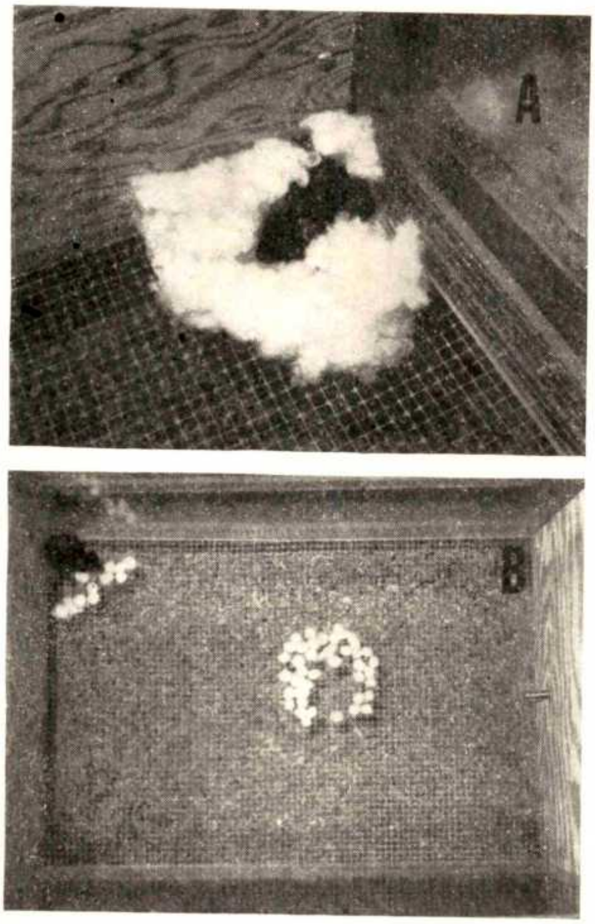

Fig. 2. *A*, Picture of a saline control taken 2 h after injection. *B*, Same animal 5 h after an injection of 100 μg/kg of LSD. The animal surrounded itself with cotton, sat in the centre for 1 h, moved to the nest site, placed the remaining cotton across the front of the area and remained in the same position for 6 h before completing the nest.

cotton balls. All drugs except D-amphetamine produced paroxysms of ear and neck scratching that were concurrent with the other competing responses, although they did not seem to interfere with the behaviour.

Table 2. PROPORTION OF ANIMALS IN WHICH VARIOUS DOSE LEVELS OF DRUGS INDUCED COMPETING RESPONSES INHIBITING RETRIEVAL OF NESTING MATERIAL

Dose level	DOM	DOET	D-Amphetamine	TMA	Mescaline
0·062	0·00	0·10	0·00	—	—
0·125	0·40	0·30	0·20	—	—
0·250	0·85	0·70	0·40	—	—
0·500	1·00	1·00	0·65	—	—
1·000	1·00	1·00	0·85	—	—
2·000	1·00	1·00	1·00	0·00	—
4·000	—	1·00	1·00	0·40	—
8·000	—	—	1·00	0·55	0·00
10·000	—	—	—	0·75	0·60
20·000	—	—	—	—	0·75
25·000	—	—	—	—	1·00

Table 2 shows the proportion of animals displaying competing responses at each dose. DOET and DOM are clearly the most potent of the drugs used. DOET is also much longer lasting, as indicated by the length of time before completion of the nest (Fig. 1). The curve for TMA (Fig. 1) suggests that the animals were developing a tolerance to the drug. But this did not seem to alter the quality of the competing response, although it shortened the duration. Tolerance was not observed with any of the other drugs.

Because our supply of LSD_{25} was limited, the results, while compelling, must remain tentative. Six animals were tested with 25, 75 and 100 μg/kg and the behavioural effects observed contained none of the characteristics of the stereotyped response induced by mescaline and the amphetamine compounds. Retrieval of the cotton may begin normally but is interrupted by frequent periods of inactivity. Some animals retrieved cotton to corners other than the nest site. Animals were observed carrying the same cotton ball from one corner to another continuously. Marked alterations in the topography and location of the nest (Fig. 2) were common. Behaviour was always altered by 100 μg/kg, and only two animals revealed any effect at smaller doses.

We thank Rose Eng and Sally Evans for technical assistance and Paul Pietsch for critical comments.

Antennae: Another Wind-sensitive Receptor in Locusts

FIVE pairs of wind-sensitive hair beds at the upper part of the head control flight posture and wing movement of locusts[1-7]. But the antennae of flies and bees are airflow receptors which regulate the insect's flight speed relative to the surrounding air and stabilize the flight course in the horizontal plane[8-12]. During tethered flight these insects hold their antennae in a characteristic flight position. Exposed to the air current of a wind tunnel, they will move their antennae actively against the direction of the air current. This movement is considered as an antennal positioning reaction, which adapts the operating range of the receptor to different air speeds[10-12].

A similar forward movement of the antennae can be seen in locusts during tethered flight in the air current from a wind tunnel. It is of interest whether this antennal movement is induced passively by aerodynamic forces or actively by the animal itself, and whether this movement is connected with flight control.

The antenna of *Locusta migratoria* consists of the basal scape, the pedicel and a number of smaller segments forming the flagellum. The joint between head capsule and scape and the joint between scape and pedicel may be moved actively by muscles[13,14], whereas the morphological arrangement of the joint between pedicel and flagellum makes possible only slight passive movements caused by exterior forces acting on the flagellum. These passive movements are perceived by mechanoreceptors of the pedicel: the organ of Johnston, another chordotonal organ and campaniform sensillae[14-16].

In locust at rest the antennae may be held in different directions. Uvarov[17] has noted that "the antennae during flight are kept in a very rigid state at an angle to the body and may serve to record changes in the direction of air currents". For the exact evaluation of antennal movements I photographed the head region of locusts in tethered flight from above, some seconds after removal of the support (subdued red light; exposure time 1 s). The "antennal angle" (γ = angle between antenna, projected in horizontal plane, and longitudinal axis of the wind tunnel) was measured on the films. The antennal position of locusts in tethered flight depends on the speed of the frontal air current: without air current the antennal angle is about 50°. With increasing air speed the antennal angle will decrease (Fig. 1, *n*).

To find out whether this decrease is a direct effect of the air current or a reaction of the animal to stimulation by air current, I had to eliminate the receptors which are possibly controlling the antennal movements. It was obvious to suggest that the receptors are the mechanical sense organs of the pedicel, because the corresponding sense organs in flies and bees control the antennal positioning reaction and the flight movements[10-12]. Moreover, Uchiyama and Katsuki have pointed out[18] that the mechanoreceptors of the pedicel of locusts can be stimulated by contact stimuli or by air current applied to the flagellum. These receptors were therefore eliminated by immobilizing the pedicel–flagellum joint with wax colophony. Neither the active movement of the head–scape joint nor those of the scape–pedicel joint were directly impaired by this operation. The antennae were able to move freely in all directions. In tethered flight, however, the antennal angle was not significantly reduced with increasing air speed (Fig. 1, *i*), as occurs in unoperated locusts (Fig. 1, *n*), but remained nearly independent from the air current. Thus in normal animals the mechanoreceptors of the pedicel indicate the air speed and control the antennal angle by means of the antennal muscles of head and scape.

To determine whether there are wind-sensitive receptors in the pedicel that influence the flight movements, the wings were photographed in the stroke plane, which was perpendicular to the optical axis of the camera. The stroke angle of the forewings (φ), as it appeared on the film, was evaluated as a convenient measure of the flight reaction. In normal animals the stroke angle decreased by about 48° after air speed had been increased from 0 to 4 m/s (Fig. 2, *n*). After immobilizing the pedicel–flagellum joint the stroke angle decreased only by about 29° (Fig. 2, *i*; the difference of decrease is significant; $P < 0.0027$). Consequently, the great decrease of the stroke angle in normal locusts during frontal air current must have been partly induced by the wind-sensitive receptors of the pedicel that were blocked during the last experiment (*i*). The decrease of the stroke angle by 29° persisting in this experiment may be caused by the wind-sensitive hair beds on the head and perhaps by other wind-sensitive receptors[3] or by aerodynamic forces.

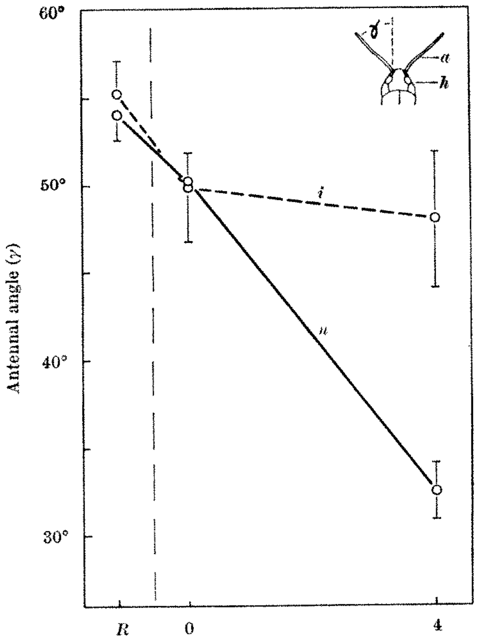

Fig. 1. Dependence of the antennal angle (γ) on the air speed of the wind tunnel. (0 m/s means that there was no air current from the wind tunnel; there was, however, an air current caused by the animal's flight movements which acted on the antenna.) Each circle represents the average value of 120 measurements (twelve for each of ten females in tethered flight). Vertical bars indicate the standard error (± *S.E.*); *a*, antenna; *h*, head; *n* normal animals; *i*, pedicel–flagellum joint immobilized; *R* marks the antennal position of the animals at rest.

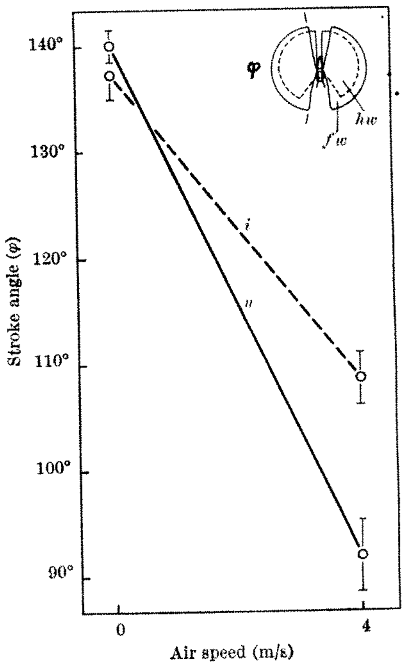

Fig. 2. Stroke angle (φ) of the forewings (*fw*) at different air speeds of the wind tunnel. *hw*, Hindwing. For other explanations see Fig. 1.

The active adjustment of the antennal angle therefore has a similar function to that of flies and bees. In all these cases it works as an antennal positioning reaction for the wind-sensitive receptors of antennae that control flight movements. Because of the active diminution of the antennal angle, the drag from frontal air current and, consequently, the bending of the flagellum with respect to the pedicel are kept relatively small. By means of the antennal positioning reaction the antennae are kept in the optimal position for a particular flight speed. Thus the wind-sensitive receptors of the pedicel are capable of fulfilling their function of measuring within a favourable range even at high flight speeds of free flying locusts.

Book Reviews

AGEING CONTROL

The Immunologic Theory of Aging

By Roy L. Walford. Pp. 248. (Munksgaard: Copenhagen, 1969.) Dkr. 97.50.

Dr Roy Walford is one of the pioneers of immunology as applied to age processes, and this book is a most powerful and critical presentation of his case. It is a tribute to the author that the book contains so much and such well organized material that, although it does present a theoretical case, it can equally be read as a general textbook of gerontology: it contains one of the best reviews of current theory and experiment to be published so far.

The association of immunological changes with age seems to be undoubted, so far as mammals are concerned. The question is whether they represent a point of access to the control of ageing—whether, in other words, ageing could be slowed or prevented clinically by slowing or preventing them. As Walford points out, several models are possible. They might represent a constant end-effect of several error processes whereby cells or molecules become not-self, or whereby, on the lines of Burnet's theory, immunocyte clones are mis-specified; they might represent one major outcome of a basic "clock" process; or they might constitute only a single group of dyshomoeostases in a general homoeostatic loss. Walford inclines to the first view—that autoimmunity cannot be ruled out as a main, if not the main, mode through which age information-loss is expressed. The possible syntheses between this outcome and the currently fancied error theories (mutation, cross-linking, free-radical attack on various systems, "error crisis" in synthetases, and clonal divergence) are all carefully explored in the light of what evidence there is.

With immunosuppression a growth-stock, it could be argued that theorizing now gives hostages to fortune. If an effective check on both humoral and tissue immunity appears shortly, the argument can probably be settled by direct trial. Of available agents, azathioprene and cyclophosphamide are highly toxic, though Walford has shown a life-prolonging effect for suitably chosen doses. The probable effects of anti-lymphocytic serum on the ageing process cannot yet be assessed, and it is in any event not as effective against humoral as against cellular immunity. If ageing autoimmune effects reflect clonal divergence, or some analogous error process, complete immunosuppression might be expected to suppress some manifestations of ageing—as anti-inflammatory agents suppress some overt pathologies—but aggravate the basic divergence. In order to control ageing, it would on this model be necessary to increase the body's censorship against mis-specified cells or molecules. Walford does not deal fully with this possibility, but it is implicit in the choice of models he advances. His reply to the argument that, autoimmune disease being apparently more prevalent in women, female life should on the autoimmune-ageing model be the shorter, is based chiefly on the selectivity of our statistics: a better case could perhaps be made on the adaptation of the female mammal to life with a half-foreign foetus. But these are perhaps the only omissions, and they derive from lack of space rather than from any reluctance of the author to deal fully and frankly with opposing arguments. In a vast body of background reading, errors are very few—perhaps the only questionable statement is that on page 150, that Tannenbaum's experiments on mouse dietary restriction gave negative results.

Our detailed knowledge of the immunology of old as against young mammals is limited, and much of what is known is due to a handful of workers, notably Walford himself and Makinodan. Many of the experimental results are, moreover, confusing to the theorist. Walford here reviews them fully, covering humoral and tissue immune mechanisms, transplantation immunity, analogies between syndromes such as amyloidosis, runt disease and progeria and the observable course of natural ageing, and the compatibility of immune models with observed or purporting modifiers of ageing rate such as radiation and calorie restriction. The actuarial and physiological criteria of ageing are fully discussed, and the author's approach to generalist theories of senescence which cover fruitflies, spiders and *Daphnia* as well as the more "immunological" phyla is robust and sensible. What might have been an indigestible or a dogmatic line is made consistently acceptable by a good prose style and a sense of proportion. In consequence the most partisan advocate of another theory of senescence is unlikely to emerge uninstructed or dissatisfied.

This is a brilliant and highly instructive performance. Gerontologists will read it with profit as a review of the contribution of immunology to their subject: immunologists and other biologists with even greater profit for the overview it gives of modern attempts to control ageing. It is rare to find a textbook which combines so fully and critically a well-argued hypothesis with a universalist survey of the entire field. Alex Comfort

HORMONES OF INVERTEBRATES

The Comparative Endocrinology of the Invertebrates

By Kenneth C. Highnam and Leonard Hill. (A Series of Student Texts in Contemporary Biology.) Pp. ix + 270. (Arnold: London, December 1969.) 80*s* boards; 40*s* paper.

This is probably the first text which covers systematically what is known about the endocrine systems of all invertebrate animals. It is an introductory text intended for the sixth form in schools and for undergraduate courses; and the authors stress the ready availability of many of these animals, notably the insects, and of some of the hormonally active chemicals, the effects of which can be demonstrated by simple class experiments. Presumably they are writing on the basis of personal experience. The book is clear and lucid throughout. About half deals with the insects which lend themselves well to hormonal studies and in which the subject is most advanced. But no attempt is made to force the endocrine system of other invertebrates into the pattern created by the insects. It is noteworthy that completely novel arrangements of great interest are beginning to be uncovered in other groups; such as the work of Burnett and Diehl on the role of neurosecretory cells in growth, regeneration and the development of sexuality in species of *Hydra*; and the work of Cheat on the release of neurosecretory substance from the radial nerves of starfish into seawater whence it is absorbed by the tube feet of the same and other individuals to precipitate the shedding of gametes.

The authors compare the neurosecretory process with the liberation of neuromuscular transmitter substances at the axon termination of ordinary neurones. But perhaps a truer comparison would be with the continuous downward streaming of the axoplasm of all neurones (carrying with it mitochondria that pile up when the axon lumen is constricted) which presumably must be liberated somewhere. So far as the insects are concerned, the section dealing with the hormonal control of reproduction is particularly good. This is the subject with which the authors' own researches have been chiefly concerned.

It is a difficult subject because the parts played by the different components of the endocrine system differ greatly even between closely related insects; but the authors manage to give a very clear and persuasive account of the whole problem. The hormonal control of growth and metamorphosis is not quite so successful. Thus they reproduce an account of the main experiments which demonstrate that the pattern of the adult body is often already laid out in invisible form in the larva—but they do not succeed in conveying the implications of these results to the reader. They produce a useful generalization about the evolution of the endocrine system, derived from the Sharrers, which must not, of course, be pursued too far: that in the more primitive invertebrates the endocrine system consists only of secreting neurones; that in the higher invertebrates (insects) there is often a two-tier system in which the neurosecretory products act on epithelial endocrine glands; and that in the vertebrates a three-tier system may occur in which the epithelial endocrine gland can exert a trophic influence on a second epithelial gland.

Altogether, this book provides a stimulating introductory account of the subject. V. B. WIGGLESWORTH

POPULATION REGULATION

Population Dynamics

By Maurice E. Solomon. (Institute of Biology's Studies in Biology, No. 18.) Pp. 60. (Arnold: London, November 1969.) 14*s* boards; 8*s* 6*d* paper.

M. E. SOLOMON's contribution to the "Studies in Biology" series is a welcome companion to its other ecological texts. Population dynamics is a difficult topic to deal with in a booklet of only 60 pages. The author's success in providing a readable and informative introduction to the field is achieved partly by clarity of expression aided by careful selection of diagrams but also by a rather restricted treatment. This is a controversial field in which rival views are strongly held and often acquire the status of dogma. The author avoids both controversy and dogma by largely limiting his discourse to density dependent processes in which negative feedback between numbers of animals (or plants) and the competitive demands of the population on some limiting resource is considered to be the main mechanism of population regulation.

The first three chapters give an account of the nature and properties of populations as units of ecological study. The concepts of population age structure, birth rate and death rate are discussed and the general notion of a potential for exponential increase resisted by limiting environmental resources is introduced.

Chapters four and five are concerned with observed fluctuations in numbers and with the mechanism underlying them. Easily understood graphs are used to show how birth and death rates and the intensity of parasitism or predation are related to population density. These density dependent processes, set in the context of a variable physical environment, are built into a generalized framework showing how the density of field populations may be determined. The inexperienced reader of this section may find some difficulty in deciding where demonstrable fact ends and informed hypothesis begins.

The parallels and contrasts made between plant and animal populations add little of conceptual value but at least serve to emphasize the current view of ecology as a corporate discipline involving the study of both animals and plants.

In spite of its brevity and hence rather restricted scope, this book will admirably serve its purpose in arousing interest in the field of population dynamics among school and first year university students. The final chapter, dealing with economic and social applications of population dynamics, is particularly opportune in this respect.

F. B. O'CONNOR

NATURAL PRODUCTS

Cyclopentanoid Terpene Derivatives

Edited by W. I. Taylor and A. R. Battersby. (Organic Substances of Natural Origin: A Series of Monographs.) Pp. x+432. (Dekker: New York, December 1969.) $26.50.

THIS publication is one of those rare volumes which I read avidly with delight and enthusiasm and was unable to put down until the last page.

It is the first comprehensive review of a field of chemistry which has developed very rapidly since 1958 when the structure of the first member of the group was elucidated. Since that time, knowledge of the cyclopentanoid monoterpenes and their derivatives has accumulated quickly. Ten years ago, the chemistry of these compounds consisted of various fragmentary areas with only tenuous interconnexions, but during the past five years there has been a rapid expansion and integration in this area of natural products. These developments have been catalysed by various events, but particularly by the demonstration that loganin and its closely associated derivatives are implicated as the central building unit of numerous indole alkaloids.

The volume includes chapters on the following topics: the iridoid glycosides and similar substances; picrotoxin; insect terpenoids and nepetalactone; monoterpene alkaloids; lower furanoterpenes; and sesquiterpene alkaloids.

This book is delightfully and tightly written in excellent English by authors who are active contributors and internationally recognized experts in the areas concerned. There are few excess words, but the essential information in each field is concisely presented. The formulae are numerous, clearly drawn and, in contrast to many publications, are generally placed immediately proximate to the relevant text. The standard of production and presentation is of a very high order and I noticed very few typographical errors: however, I have two minor criticisms. In chapter two there are intermittent examples of confusion between the singular and plural of the word "spectrum". In the same chapter and also in chapter four, there are several rather infelicitous statements as, for example, on page 254, line 4, where we have the comment that "these two protons appear as a singlet". But this is a minor caveat.

The authors and editors are to be complimented on a singular service to chemistry and biochemistry in general and to natural products in particular, while the publishers are to be congratulated on the speed of production. Although the official date of publication is 1969 there are even a few references from that year: references from 1967 and 1968 are numerous. If only some other publishers would follow this commendable example! This book may be recommended unreservedly to all who have any interest in this area, although the high price may regrettably deprive it of a well merited place on many private bookshelves. W. B. WHALLEY

PIONEERING RADIATION PHYSICS

The Photographic Action of Ionizing Radiations in Dosimetry and Medical, Industrial, Neutron, Auto- and Microradiography

By R. H. Herz. (Wiley Series on Photographic Science and Technology and the Graphic Arts.) Pp. xviii+629. (Wiley (Interscience): New York and London, December 1969.) 215*s*.

EVER since the first radiograph was taken in 1895, the photographic plate or film has probably been the most widely used method of detecting and measuring ionizing radiations. For specific purposes, many other methods of detection and measurement have been developed, but wherever it is necessary to integrate the effects of radiation over a period or to produce a permanent record, the photographic emulsion has remained supreme. Since 1945 there has been a spectacular rise in the available range of ionizing radiations and particles and in their applications in science and technology. This has called for new and more sophisticated measurement techniques and, alongside the developments of electronic and solid state methods, the photographic emulsion has surprisingly kept pace with the demands.

With most, if not all, of the post-war advances in the production of new photographic materials and their use with ionizing radiations, the name of Herz of Kodak has been associated. Now, in his "retirement", Dr Herz has brought together in this volume a remarkable résumé of a lifetime's activity in this field. This is not a single textbook but effectively several textbooks in one. The first five chapters give an elementary outline of radiation physics, photography and the photographic effects of ionizing radiations. They could well serve as an introductory text for any radiologist, radiographer or physicist entering the field. Chapter six, on photographic dosimetry, could be a valuable handbook for workers in radiation monitoring and so-called health physics. Chapters seven to ten represent a 220 page textbook of radiographic technique which many examination candidates would find useful. The final chapters on neutron radiography, autoradiography and microradiography summarize most impressively the more advanced fields in which the back-room work of Herz has been most effective. Throughout the book, although phenomena are well described and theories discussed, the emphasis is on the practicalities of techniques and operations. As might be expected from such a source, the diagrams and plates are excellent and, in particular, the microradiographs and autoradiographs would bring joy to photographer, scientist or artist.

In some ways it is a pity that this one volume covers so much ground, in that no single user could possibly become involved in all the sections. Nevertheless, it is a substantial monument to the work of a great pioneer in the field. J. E. ROBERTS

PHYSICAL BIOCHEMISTRY

Theoretical Biochemistry

Physico-chemical Principles of Vital Processes. By Hans Netter. Translated and edited by J. H. Ottaway and F. M. Irvine. Pp. xx + 928. (Oliver and Boyd: Edinburgh, 1969.) 300*s*.

THE design of courses on physico-chemical topics for biochemists presents many problems. The basic material with its formalisms can only be presented as physical chemistry. At that stage too many asides on biochemical applications, which are usually rather more complicated, only confuse the students. For a course of physical chemistry applied to biochemical systems one should accept as read a good first course in physical chemistry. Unfortunately this idealized situation, which would permit the presentation of sophisticated treatments of the analysis of biochemical systems, is not usually possible. Many students of biochemistry have a totally inadequate mathematical and physical background and are unable to cope with the complexities of the physical chemistry of biological problems. As a result most courses, including my own, have to revise basic physical chemistry and fit in applications where they can. The textbooks follow suit.

The text under review covers an enormous range of topics from atomic and molecular structure to biological organization by way of static and dynamic equilibria and kinetic control. Every chapter is interspersed with a certain amount of information about biological systems. One might expect the subject matter to be dealt with in some depth in 900 pages. Alas, this hope is frustrated by heavy dilution with irrelevant historical material and a rather confused presentation of the results of out of date experiments. My overall impression was that, though the book is out of date, the problems it poses are still with us. It so happens that an old copy of Sir William Bayliss's *Principles of General Physiology* in the Kendal public library inspired me 30 years ago with an interest in the application of physical methods to the study of biological systems. The book under review has the same philosophy behind it. It is somewhat more molecular in its approach, but the molecules are still very rigid.

Major deficiencies of the translation are, first, out of date and inaccurate data and references and, second, the often quite painful English.

In spite of my many criticisms I find it very valuable to have this detailed account of Professor Netter's presentation of "Theoretical Biochemistry". It will certainly help me in the preparation of some lectures and it should be useful for advanced students. The book is, however, not a substitute for some of the texts on special topics in physical biochemistry. Several of these could be bought for the price of the text under review. H. GUTFREUND

PROPERTIES OF MATTER

The Mechanical Properties of Matter

By M. T. Sprackling. (The Bridge Series.) Pp. xii + 144. (English Universities Press: London, February 1970.) 26*s*.

THIS is a very nicely written and clearly illustrated book covering a selected set of properties of matter at a level suitable for sixth forms in schools and first year undergraduates in some universities. The topics covered in seven chapters are: elastic properties of matter, plastic deformation of solids (crystals), fracture (of crystals), liquid viscosity, viscosity of gases and surface effects. The whole contains a very clear exposition with apposite choice of experimental data to illustrate the theory, and with a carefully selected set of examples at the ends of the chapters.

In a book of this size it is difficult to include everything necessary for the student, so that some sections will remain obscure to the tyro: for example, the difference between total and free energy of a surface. As I read the book I felt myself continually urging the author to go further, with the same clear exposition. This is a measure of its quality: I am sure that the student will be inspired to do so himself. A. KELLY

HIGH LEVEL FLOW

Flow Through Porous Media

Edited by Roger J. M. De Wiest. Pp. xiii + 530. (Academic Press: New York and London, October 1969.) 210*s*.

THIS book consists of a collection of state-of-the-art reviews on a variety of topics connected with fluid flow through the upper layers of the Earth's crust. Its contents are derived from lectures presented at an institute in hydrology for college teachers sponsored by the National Science Foundation, held at Princeton University in the summer of 1965. The original material for each of the eleven chapters has been revised and brought up to date for publication.

An essential ingredient of a multi-author volume of this type is a comprehensive opening chapter, which lays the foundations for the succeeding material. The editor's chapter one ("Fundamental Principles of Ground-Water Flow") is disappointing in this respect. Too many topics are covered too briefly, giving the book the appearance of a collection of essays rather than a coherent whole.

With the exception of chapter two by S. N. Davis ("Porosity and Permeability of Natural Materials"), which contains a summary of the available experimental information on these parameters for different rock types, the book demands a sound grasp of mathematical physics on the part of the reader. The chapters vary considerably in length. Chapter three by R. R. Rumer ("Resistance to Flow through Porous Media") and chapter five by E. S. Simpson ("Velocity and the Longitudinal Dispersion Coefficient in Flow through Porous Media") form short yet comprehensive treatments of their subjects. Chapter seven by D. Dicker, chapter nine by G. de Josselin de Jong and chapter ten by the editor are longer, and require a good mathematical background to be appreciated fully.

In dealing with unsteady flows in a compressible porous medium in chapter eight, A. Verruijt reviews material drawn from the literature of both soil mechanics and hydrology. A similar interdisciplinary approach is adopted by H. J. Morel-Seytoux in chapter eleven which draws upon experience in the petroleum industry.

Chapter six by D. Swartzendruber ("The Flow of Water in Unsaturated Soils") presents an interesting blend of theory and experimental results; in this respect, this is the most balanced contribution in the book. Finally, in introducing the longest chapter, J. Bear (chapter four) takes care to point out that his review of hydrodynamic dispersion is incomplete, a testimony to the literature explosion on this aspect of porous media flow.

In general, this type of book is prone to lack of uniformity in both notation and the level of competence required of the reader. As the editor, Dr De Wiest is to be congratulated on avoiding these pitfalls. The level of presentation, however, is very high—postdoctoral rather than postgraduate. The standard is certainly above that of most one-year MSc courses, irrespective of basic discipline, and the appeal of the book seems limited to research workers in this particular field. The prospect of a small circulation is reflected in the price. M. J. HALL

COLLECTED EARTHWORKS

The Seismicity of the Earth

1953–1965. By J. P. Rothé. (Earth Sciences, No. 1.) Pp. 336. (Unesco: Paris, 1969.) 48 francs; $12; 72*s*.

THIS is, against all the odds, a splendid book and one which seismologists may well feel they need themselves as well as having access to in a library. I must admit that at first glance I feared this book would be of little value. It is unashamedly a successor to Gutenberg and Richter's classic *Seismicity of the Earth*, and re-runs do not normally arouse much enthusiasm. Further, the recent compilation of US Coast and Geodetic Survey epicentres since 1961 by Barazangi and Dorman might seem to have saturated the subject. Not at all.

The study of seismicity is more than just a process of geographical cataloguing. Variation in activity with time, loss of life and damage to property, sorting of events by magnitude and the merging of seismic data into tectonic concepts—these are all important aspects of seismicity studies, and Professor Rothé has achieved a good balance of hard facts and general speculation. He has drawn on a wide variety of sources and his bibliography is superb—nobody studying local seismicity should venture on an area until he has followed up all Rothé's leads. Further, he makes wide use of the seismological notes of the *Bulletin of the Seismological Society of America*—an invaluable compilation which earns too little credit for its editor.

After an intelligent introduction surveying global seismic activity, the regions of the world are reviewed in turn, maintaining the same layout as Gutenberg and Richter. Bilingual (English and French) comments follow the listing of all earthquakes between 1953 and 1965 with a magnitude greater than about 6·0. The magnitude criterion is relaxed, however, when small earthquakes have occurred in unusual locations or have wrought considerable damage. At the end of the book a set of maps show locations, together with some notable faults and nuclear tests.

The whole is well produced and handsomely printed. The translation is first-rate. It is difficult to find fault with this invaluable work of reference, which is going to save hours of thumbing through journals, maps and cards. D. DAVIES

TRIANGULAR PUZZLES

Geometric Inequalities

By O. Bottema, R. Ž. Djordjević, R. R. Janić, D. S. Mitrinović and P. M. Vasić. Pp. 151. (Wolters-Noordhoff: Groningen, 1969.) $4.90.

THE book consists of a list of some four hundred inequalities on triangles and a further sixty on quadrilaterals, polygons and circles. A good many have a proof or some indication of a proof and nearly all are elementary in nature. Some, however, would provide testing exercises for any mathematician, even though the majority would be of most interest to secondary school students. Hardly any of the examples require any previous knowledge. Many are of the type which says that there is a maximum or minimum in the most symmetric case. For example, if A, B, C are the angles of a triangle, then

$$\sin A+\sin B+\sin C\leq 3\sqrt{3}/2;$$

or, if h_a, h_b, h_c are the altitudes of a triangle, then

$$(3r)^3\leqslant h_a h_b h_c\leqslant(3R/2)^3$$

where r and R are the radii of the incircle and circumcircle respectively; or, the area of an n-gon inscribed in a unit circle is at most that of the regular one, namely, $(n/2)\sin(2\pi/n)$. It is mentioned that the last example was set in a high school students' competition in China in 1957. The book would be a useful addition to any school library although, it must be said, it does not greatly extend the imagination, which a book of puzzles ought to do. More precisely, even though most of the book is devoted to triangles, the more interesting examples are in the last three sections of the book. For example, if a regular hexagon of area F contains non-intersecting circles of radii $r_1, \ldots, r_n$, then

$$(r_1+\;.\;\;.\;\;.\;+r_n)^2\leq nF/\sqrt{12}$$

References to all the results are given. Finally, the authors are to be admired for their assiduity in achieving such a complete collection. JAMES HIRSCHFELD

Obituaries

Dr G. S. Carter

GEORGE STUART CARTER was born on September 15, 1893, the son of the Rev. G. C. Carter and Hilda E. Keane. His schooling was at Marlborough College and it was probably there that he gave his first scientific paper, as evidenced by the entry "G. S. Carter . . . Ants" in the record of the Marlborough College Natural History Society for February 5, 1912. This youthful endeavour was the precursor of a lifetime's work in biology.

He went up to Gonville and Caius College, Cambridge, and read for Part I of the Mathematics Tripos in 1913. The First World War then called him to serve until 1919, first in the Leicestershire Regiment and later in the Royal Engineers. Returning to Cambridge he read for Part II of the Natural Sciences Tripos in Zoology, gaining a First and being awarded the Frank Smart Prize and Studentship in 1921. His highly productive career started with the publication, while he still held the studentship at Gonville and Caius, of papers on the structure and movement of cilia in *Mytilus* and on the early development of the echinoderm egg. Two other papers on veliger cilia followed after his move to a lectureship at Glasgow, and it is clear that this early work was influenced by Sir James Gray, who was two years his senior and held the Balfour Studentship at Cambridge during Carter's time as a Part II student. His work from Glasgow at the Millport Marine Station, where he was much encouraged by Richard Elmhirst, and at Naples, led to a further nine papers on sperm and fertilization in *Echinus* and *Asterias* and concluded the first recognizable phase in his work, largely concerned with invertebrate physiology. He returned to a lectureship in Cambridge and a fellowship at Corpus Christi College in 1930, holding the former to his retirement in 1960 and the latter until his death.

A new facet of Carter's wide ranging biological interests opened up with his expeditions in the 1920s and 1930s to Brazil, the Paraguayan Chaco and to British Guiana, and subsequently in the middle 1950s to Jinja and the papyrus swamps on Lake Victoria. Substantial papers with Beadle on the South American work, a biological review, and other papers of his own followed, covering all aspects of that fascinating environment, the tropical swamp, and dealing with adaptations largely of fish and oligochaetes to this taxing mode of life. It would seem clear that his great interest in evolution arose during this work. The material collected on these expeditions was worked upon by Gurney, Lowndes and Jepps, among others, and was of wide influence.

It was perhaps in his final and maturest phase, as a writer of substantial general texts, that Carter exerted his most profound influence on the development and teaching of zoology. His *General Zoology of the Invertebrates*, first published in 1940 and running to four editions by 1961, remains a model of readable analysis and instructive information, and his *Animal Evolution* (1951) and *A Hundred Years of Evolution* (1957) were of equal value to the student and the general reader respectively. He continued writing until the beginnings of his final illness and happily saw *Structure and Habit in Vertebrate Evolution* published in 1967. This late work is perhaps the best tribute to his versatile and enquiring mind, for it forms a synthesis of physiological, structural and behavioural knowledge in this field which shows most clearly his ability to develop a new and profitable approach to an old problem in the light of a lifetime's experience of enquiry.

Although this is meant primarily to be an account of his published contributions to knowledge, the moment cannot be allowed to pass without also recording the appreciation of generations of undergraduates and colleagues who were alike given his stimulating, critical but kindly advice and encouragement. He was much loved and will be much missed by many friends.

Correspondence

Should Slides be seen Blind ?

SIR,—I fully endorse the views expressed by Roe *et al.*[1] on the subject of histological examination using a "blind" technique.

In this sort of examination the pathologist often has to decide whether the abnormality he finds could have been the result of a natural disease process rather than of a specific insult from administration of the test substance. Such a distinction may be difficult or even impossible without a knowledge of necropsy findings and of lesions in the other animals on the same regimen of treatment.

Assessment of minor degrees of change resulting from toxic damage is one of the principal objects of safety evaluation tests. Such minor changes often cannot be readily distinguished from variations in the normal appearance of tissues, or from a processing artefact, without information relating to level of treatment, state of health of the animals, and necropsy findings.

In the clinical field the pathologist relates his findings and opinion to the clinical history and biochemical results. Only by following the same procedure in experimental animal studies can a sound pathological opinion be given of any lesions.

Efforts to examine pathological material from toxicity tests "blind" have been made in the past and they have been met with unqualified disfavour by pathologists. Dr A. A. Nelson, one of the pioneers in the field of pathological examination of animal tissues from toxicity tests, when asked whether he would advise this sort of procedure[2] replied, ". . . my own feeling is that a person that couldn't give a reliable opinion if he had the data would give a worse one without it. . . . The truly blind and random reading, I think, will result in the pathologist having wider limits of normality than he otherwise would have, and eventually what is actually a mild but definite effect will be passed off as within those broad normal limits"[1].

Yours faithfully,

P. GRASSO

Chief Pathologist,
British Industrial Biological
Research Association,
Woodmansterne Road,
Carshalton, Surrey.

Another *Acanthaster* Disaster

SIR,—Possible biological consequences of establishing an open waterway between the eastern Pacific and the Caribbean have recently been pointed out by several scientists[1-5]. These consequences include interactions between closely related species as well as between unrelated species. Conceivably the results of either could, from man's viewpoint, be detrimental or beneficial. Generally biologists have warned of possible bad effects of uncontrolled biological exchange between the two oceans, although Topp[4] offers a guarded opinion that the characteristics of the fish faunas, at least, will not be drastically altered.

Introductions of foreign species leading to undesirable results are well known, and to ignore the probability of a plethora of serious problems resulting from free migrations through a sea-level canal is the height of folly, but unfortunately it is difficult to predict which organisms will cause trouble in new environments. Without intensive study, only obviously inimical species can be singled out.

Weathersbee[5] has valid fears about the possible introduction of the poisonous sea snake, *Pelamis platurus*, into the Caribbean through a sea-level canal, but *Acanthaster ellisi* (Gray), the eastern Pacific crown-of-thorns starfish, may present an even greater potential danger to the Caribbean. Wholesale destruction of coral reefs by the Indo-Pacific crown-of-thorns, *A. planci*, has received considerable attention recently[6-9] and the problem has become so acute that Chesher[6] has expressed fears for the future of Pacific reefs. *Acanthaster ellisi* is so similar to its Indo-Pacific relative that separation of the two species has been questioned (personal communication with J. Halpern, University of Miami). Presumably it eats coral, although nothing is known about its biology. It is thought to be rare[10], and population growth is possibly limited by a lack of suitable coral growth in the eastern Pacific.

The known distribution of *A. ellisi* includes the Gulf of California and nearby Socorro and Clarion Islands[11,12]. The adults do not appear to extend to the Isthmus, but their distribution is not well known.

If the crown-of-thorns were to invade the Caribbean it would find a lush habitat to exploit in the present extensive coral biotope. A population explosion on a scale comparable with that of its Indo-Pacific relative would be disastrous.

An invasion of the Caribbean by *A. ellisi* is entirely possible should a sea-level canal be constructed without a barrier to the free distribution of marine animals. The alternative to risking invasions into either ocean by potentially dangerous foreign species is patently clear; construction of a suitable biological barrier in any new trans-isthmus canal.

Yours faithfully,

Pulses, Units, Pitts and Hertz

Sir,—I refer to Stark's letter[1] proposing a new unit of frequency, pitts, for nerve pulses per second, which would simplify the use of neurophysiological papers and graphs. I wish to point out that the results of radioactivity measurements are likewise expressed in pulses (counts) per unit time, and that some confusion exists concerning units of frequency, because no distinction is made between periodic and aleatory phenomena.

Frequencies of periodic phenomena are expressed in Hertz units (with dimension s^{-1}), an accepted derived unit in the International System of Units (SI). The same dimension applies to averaged frequencies of aleatory phenomena like those mentioned in the preceding paragraph; the word "averaged" is intended to imply that the duration of the measurement is appreciably larger than the statistical frequency of the aleatory phenomenon. According to the latest ICRU report on radiation quantities and units[2], the unit for activity, the Curie (accepted by SI), is defined as $3{\cdot}7\times10^{10}$ nuclear transformations (that is disintegrations or isomeric transitions) per second. However, in accordance with the former definition of the Curie as a unit of quantity of a radioactive nuclide, the presently accepted definition of the Curie includes the words ". . . nuclear transformations occurring in a *quantity* of radioactive nuclide per second", although the italicized part is irrelevant since the dimension of the Curie unit is s^{-1}.

Until a treaty for the non-proliferation of scientific units (and journals) has been signed, I support Stark's proposal[1], with the proviso that frequencies of periodic phenomena should be expressed in Hertz, results of absolute measurements of radioactivity in Curie, and averaged frequencies of aleatory phenomena (including results of relative measurements of radioactivity) in a new unit (all these three units have s^{-1} as dimension). It would have been better to have only two frequency units, one for periodic and the other for aleatory phenomena, but this seems to be no longer possible.

Yours faithfully,

Alexandru T. Balaban

University News

Dr Donald G. Rea, NASA, has been appointed to the newly created post of assistant laboratory director for science at the Jet Propulsion Laboratory, **California Institute of Technology.**

Professor C. R. O'Dell has been reappointed chairman of the Department of Astronomy and Astrophysics and director of the Yerkes Observatory, and **Professor Eugene N. Parker** has been appointed chairman of the Department of Physics, in the **University of Chicago.**

Dr Eli Chernin has been appointed professor of tropical public health in the Faculty of Public Health, **Harvard University.**

Professor Richard H. Greenwood, University of Queensland, has been appointed to the second chair of geography, at the **University College of Swansea.**

Appointments

Professor J. Cruickshank, University of Sussex, has been appointed to membership of the **University Grants Committee,** and **Professor C. E. H. Bawn,** University of Liverpool, **Professor R. C. Cross,** University of Aberdeen, and **Professor J. Diamond,** University of Manchester, have been reappointed.

Corrigendum. At a meeting of the Parkinson's Disease Society on February 11 the impression arose that patients involved in trials of L-dopa would have to stop taking the drug when trials are completed. (*Nature*, **225**, 675; 1970.) Professor J. N. Walton, chairman of the MRC working party on L-dopa, has pointed out that this is not correct, and that patients who benefit from L-dopa have been guaranteed a continuing supply after completion of trials.

International Meetings

April 7–10, **Bio-Medical Engineering,** Oxford (J. D. Gasking, Department of Pharmacology, The Medical College of St Bartholomew's Hospital, Charterhouse Square, London EC1).

April 9–10, **Metabolism and Biological Functions of Polyamines,** New York (New York Academy of Sciences, 2 East 63rd Street, New York, NY 10021, USA).

April 14–16, **Handling Current Records,** London (Education Officer, Aslib, 3 Belgrave Square, London SW1).

Sabbatical Itinerants

In the hope of providing some practical assistance in the good cause of mobility between laboratories, *Nature* advertises the needs for housing of families about to take up periods of sabbatical leave. To begin with, no charge will be made for advertisements like this. It is hoped that a period of experiment will show what form these advertisements could most usefully take and whether they are effective.

Wanted: Furnished, centrally heated house or flat in Hampstead or vicinity for medical sociologist, wife and three children, for one year beginning September 1970. Please contact Dr Robert S. Weiss, Department of Psychiatry, Harvard Medical School 58 Fenwood Road, Boston, Massachusetts 02115, USA.

Wanted: Partially or fully furnished house or flat with 3 bedrooms and central heating in north central London, for a period of 10 months to 1 year beginning August 15 to September 1, 1970. Please contact Professor James A. Olson, c/o The Rockefeller Foundation, GPO Box 2453, Bangkok, Thailand.

Wanted: 3- or 4-bedroomed, furnished house with a small garden for an Oxford botanist and family, near the University of Berkeley, California, from January 12 to the end of August 1971. Please contact Dr B. E. Juniper, Botany School, Oxford University, South Parks Road, Oxford, OX1 3RA.

Vacant: 4- or 5-bedroomed detached modern house, fully automatic central heating, fully furnished, with double garage and large garden, 4 miles from centre of Oxford. Available December 15, 1970, to the end of August 1971. Please contact Dr B. E. Juniper, Botany School, Oxford University, South Parks Road, Oxford, OX1 3RA.

Vacant: Centrally heated house, near Harpenden, Hertfordshire. Good rail service (30 minutes) to London. 3 bedrooms, study (or fourth bedroom), living room, dining room, kitchen, bathroom, double garage and easily maintained garden. Available from end of September 1970, for one year. Please contact J. C. Gower, Department of Statistics, Rothamsted Experimental Station, Harpenden, Hertfordshire.

Vacant: From mid-June to mid-September, 2-bedroomed house in Cambridge; fully furnished, central heating, garage. Please contact Dr N. L. Malcolm, 255 Campkin Road, Cambridge.

Vacant: From early July to early September 1970, 5-roomed groundfloor flat in London, WC1. Central heating, key to private garden with tennis court. Please contact Dr J. A. Edgington, 19 Mecklenburgh Square, London WC1 (telephone 01-837 7800).

Vacant: 3-bedroomed furnished house in Bethesda, Maryland, within walking distance of the National Institutes of Health. Available June to September 1970. Central air-conditioning. Please contact Dr Gerald Ehrenstein, Biophysics Laboratory, NIH, Bethesda, Maryland, 20014, USA.

Vacant: From July 23, 1970, until end of August 1971, furnished, centrally heated detached house with 4 bedrooms, garage and garden. 32 minutes by rail from London; close to country. Please contact Dr Robert Spence, Department of Electrical Engineering, Imperial College, Exhibition Road, London SW7.

British Diary

Monday, March 30

Rubber Blank Preparation (6.45 p.m.) Mr P. D. Lanham, Institution of the Rubber Industry, at the Waldorf Hotel, Cooper Street, Manchester 2.

Tuesday, March 31

Yield, Deformation and Fracture of Polymers (four-day symposium) Society of Chemical Industry; jointly with the British Polymer Physics Group, British Society of Rheology; Institution of the Rubber Industry; Plastics Institute; Materials Science Club; Institute of Physics and the Physical Society, at Churchill College, Cambridge.

Wednesday, April 1

Chemical Engineering in the Pharmaceutical Industry (2 p.m. symposium) Institution of Chemical Engineers, at Heriot-Watt University, The Grassmarket, Edinburgh.

Direct Digital Measurement of Physical Quantities (6 p.m. discussion) Institution of Electronic and Radio Engineers, at 9 Bedford Square, London WC1.

Electrical Measurement on Acoustic Surface Wave Devices (5.30 p.m. discussion) Institution of Electrical Engineers, at Savoy Place, London WC2.

The Interaction of Pesticides and Herbicides with Biochemical Systems; and Scientific Papers (two-day meeting) Biochemical Society, at the University College of Wales, Penglais, Aberystwyth.

The Use of Aluminium Cables in Industry (5.30 p.m. discussion) Institution of Electrical Engineers, at Savoy Place, London WC2.

Thermodynamics (four-day international conference) Institute of Physics and the Physical Society, at University College, Cardiff.

X-ray Analysis—Past, Present and Future (three-day Bragg symposium) Royal Society's National Committee for Crystallography; Institute of Physics and the Physical Society; and the International Union of Crystallography, at the Royal Institution, 21 Albemarle Street, London W1.

Thursday, April 2

Can Economic Control Models ever Work in Real Life? (5.30 p.m. discussion) Institution of Electrical Engineers, jointly with the Institute of Measurement and Control; and the Automatic Control Group of the I.Mech.E., at Savoy Place, London WC2.

Measurement Audits (Laboratory Inter-comparisons) (5.30 p.m. discussion) Institution of Electrical Engineers, at Savoy Place, London WC2.

Moulding to Tolerance (6.30 p.m.) Mr T. R. Weal, Plastics Institute, at Imperial Chemical Industries, Ltd., Britannia House, 50 Great Charles Street, Birmingham 3.

Friday, April 3

Accurate Methods of Analysis for Major Constituents (two-day meeting) Society for Analytical Chemistry; and the Analytical Chemistry Section of the Koninklijke Nederlandse Chemische Vereniging (Royal Dutch Chemical Society), at Imperial College, London SW7.

Aeronautical Communication by Satellite (5.30 p.m. discussion) Institution of Electrical Engineers, at Savoy Place, London WC2.

Cultured Human Cells and the Biology of Senescence (4.30 p.m.) Professor Leonard Hayflick, National Institute for Medical Research, at Mill Hill, London NW7.

Implementation of Digital Filters (5.30 p.m.) Professor R. Boite, Institution of Electrical Engineers, at Savoy Place, London WC2.

The Engineer and His Development in Society (9.30 a.m. symposium), Society of Engineers, on board the *M.V. Suerita*, Westminster Pier, London SW1.

Monday, April 6

Bio-Engineering 1970 (six-day conference) Biological Engineering Society, at the University of Oxford.

Modern Electronic Instrumentation (five-day vacation school) Institution of Electrical Engineers, at the University College of North Wales, Bangor, North Wales.

Multi-Element Phased Arrays (5.30 p.m. discussion) Institution of Electrical Engineers, at Savoy Place, London WC2.

Operational Research in the Chemical Industry (6.30 p.m.) Society of Chemical Industry, at 14 Belgrave Square, London SW1.

Post-graduate School on Absorption, Distribution and Metabolism of Drugs (5 days) Pharmaceutical Society of Great Britain, at Chelsea College (University of London), Manresa Road, London SW3.

Scientific Papers on Aspects of Mammalian Development (two-day meeting) British Society for Developmental Biology, in the Department of Zoology, University of Cambridge.

Spring Conference (three days) Association for High Speed Photography, jointly with the Shock Tube Liaison Group, at the University of Liverpool.

The Chemistry and Mineralogy of Meteorites and Extraterrestrial Matter (three-day symposium) Mineralogical Society of Great Britain and Ireland; the Meteorological Society and the International Association of Geochemistry and Cosmochemistry, at the British Museum (Natural History), London SW7.

US Department of the Interior: Geological Survey. Water-Supply Paper 1921: Surface Water Supply of the United States 1961–65. Part 7: Lower Mississippi River Basin. Vol. 2: Arkansas River Basin. Pp. ix + 878. Water-Supply Paper 1935: Quality of Surface Waters of the United States 1964. Parts 5 and 6: Hudson Bay and Upper Mississippi River Basins, and Missouri River Basin. Pp. xi + 462. $2. Water-Supply Paper 1957: Quality of Surface Waters of the United States 1964. Parts 7 and 8: Lower Mississippi River Basin and Western Gulf of Mexico Basins. Pp. xii + 602. $2.50. (Washington, DC: Government Printing Office, 1969.) [61

Papers presented at a Symposium on Natural History Collections: Past—Present—Future. Edited by Daniel M. Cohen and Roger F. Cressey. (Proceedings of the Biological Society of Washington, Vol. 82. Pp. 559–762.) (Washington, DC: Biological Society of Washington, National Museum of Natural History, 1969.) $4. [61

Field Museum of Natural History. Fieldiana: Zoology. Vol. 51, No. 13 (September 30, 1969): New Birds from Camiguin South, Philippines. By Austin L. Rand and D. S. Rabor. Pp. 157–168. (Chicago: Field Museum of Natural History, 1969.) [61

Science, Technology, and Public Policy: a Selected and Annotated Bibliography. Vol. 2: Articles in Journals. Edited by L. K. Caldwell, assisted by W. B. DeVille and G. W. Lindesmith. (Prepared for the National Science Foundation by the Program of Advanced Studies in Science, Technology and Society, Department of Government, Indiana University.) Pp. xii + 544. (Bloomington, Indiana: Indiana University, 1969.) [61

Australia. Commonwealth Scientific and Industrial Research Organization. Annual Report of the Wool Research Laboratories, 1968/1969. Pp. 70. (Melbourne: CSIRO, 1969.) [71

Republic of South Africa. 35th Annual Report of the Director of Sea Fisheries for the calendar year 1967. (Reprint from *Commerce and Industry*.) Pp. 35. (Sea Point, Cape Town: Department of Industries, Division of Sea Fisheries, 1969.) [71

Institute of Applied Science of Victoria. Report of Activities 1967/1968. Pp. 24. (Melbourne: Institute of Applied Science of Victoria, 1969.) [71

Twenty-fourth Annual Report of the Council of the Queensland Institute of Medical Research for the year ended June 30, 1969.) Pp. 20. (Brisbane: Queensland Institute of Medical Research, 1969.) [71

US Department of the Interior: Geological Survey. Professional Paper 562-D: Response of a Laboratory Alluvial Channel to Changes of Hydraulic and Sediment-Transport Variables. By R. E. Rathbun, H. P. Guy and E. V. Richardson. Pp. iii + 32. $0.40. Professional Paper 614-C: The October 1963 Eruption of Kilauea Volcano, Hawaii. By James G. Moore and Robert Y. Koyanagi. Pp. iii + 13 + plate 1. Professional Paper 614-E: Distribution of Thorium, Uranium, and Potassium in Igneous Rocks of the Boulder-Batholith Region, Montana, and Its Bearing on Radiogenic Heat Production and Heat Flow. By Robert I. Tilling and David Gottfried. Pp. iii + 29. $0.40. Paper 627-A: The Precipitation Regime of Long Island, New York. By J. F. Miller and R. H. Frederick. Pp. vi + 21 + 1 plate. Professional Paper 680-B: Petrology of the Basalt Cores from Midway Atoll. By Gordon A. Macdonald. Pp. iii + 10. $0.25. (Washington, DC: Government Printing Office, 1969.) [91

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one copy of NATURE each week is:

12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire.................................**£14 0 0** each
United States of America........(by air freight)..........**$48** each
Canada............................(by air freight)......**$52** each
Elsewhere overseas by surface mail...................**£14 0 0** each
(Charge for delivery by air mail on application)
*Shorter periods *pro rata*. (Minimum three months.)

NEW TECHNICAL AND SCIENTIFIC DICTIONARIES

RUSSIAN-ENGLISH SCIENTIFIC AND TECHNICAL DICTIONARY

Two volumes

M. H. T. and V. L. ALFORD

Contains approximately 100,000 entries covering some 50 subjects. Grammatical and subject information is included where relevant and these volumes include a table of equivalent letters, prefixes, transliteration schemes and inflexions.

Volume 1 780 pages Volume 2 652 pages—£15 set

POLYTECHNICAL DICTIONARY

Volume 1—English/German
Volume 2—German/English

Edited by RUDOLF WALTHER with the co-operation of MARTIN STRAUSS

Featuring some 100,000 terms and words this remarkable comprehensive dictionary bridges the gap between the general, non-technical and specialized subject dictionaries.

Volume 1 1,256 pages £10 Volume 2 1,054 pages £10

RUSSIAN-ENGLISH SPACE TECHNOLOGY DICTIONARY

MICHAEL M. KONARSKI

Provides more than 10,600 terms in the fields of satellite and other spacecraft design and exploitation.

928 pages £10 hard cover

Set with Russian–English Dictionary of Modern Terms in Aeronautics and Rocketry *£15 hard cover*

FOUR-LANGUAGE TECHNICAL DICTIONARY OF DATA PROCESSING, COMPUTERS AND OFFICE MACHINES English/German/French/Russian

ERICH BURGER with the co-operation of Wolfgang Schuppe

An invaluable multilingual dictionary presenting some 13,000 terms in the rapidly developing areas of Data Processing, Computers and Office Calculating Machines. Arranged in four sections, each giving a side-by-side comparison of the terms in all four languages, employing the alphabetical order of each language in turn.

1,464 pages £12 hard cover

ALSO AVAILABLE

MULTI-LINGUAL

FOUR-LANGUAGE DICTIONARY OF ELECTRONICS

English/German/French/Russian

Compiled by P. NEIDHARDT

1,664 pages £14 10s.

FIVE-LANGUAGE DICTIONARY OF SURFACE COATINGS, PLATINGS, PRODUCTS FINISHING, CORROSION, PLASTICS AND RUBBER

English/Czech/Russian/German/French

ROBERT W. SANTHOLZER

582 pages £8

DICTIONARY OF CHEMISTRY AND CHEMICAL TECHNOLOGY —2nd Edition

English/German/Polish/Russian/French/Spanish

Compiled by H. STEPHEN, T. STEPHEN and Z. SOBECKA

1,108 pages £11 12s.

DICTIONARY OF NUCLEAR PHYSICS AND TECHNOLOGY

English/French/German/Russian

Contains 17,000 terms.

Compiled by R. SUBE

1,600 pages £11 12s.

DICTIONARY OF AUTOMOTIVE ENGINEERING

English/German/Russian/French

Includes 10,000 terms

Edited by W. MÜLLER

860 pages £11 12s.

INTERNATIONAL DICTIONARY OF REFRIGERATION

English/French/German/Russian/Spanish/Italian

Compiled by the Institut International du Froid

264 pages 81s.

TECHNICAL DICTIONARY OF HIGH POLYMERS

English/German/French/Russian

W. DAWYDOFF and H. HOWORKA

968 pages £11

BI-LINGUAL

CONCISE RUSSIAN/ENGLISH SCIENTIFIC DICTIONARY FOR STUDENTS AND RESEARCH WORKERS

Compiled by A. BLUM,
Imperial College, London

124 pages 20s hard cover
12s 6d flexi-cover

SHORTER TECHNOLOGICAL DICTIONARY

English/Polish, Polish/English

Edited by S. CZERNI and M. SKRZYNSKA

400 pages 81s.

Please write for a fully descriptive brochure on all Dictionaries available, to the **Marketing Manager, Pergamon Press, Headington Hill Hall, Oxford, OX3 0BW.**

APPOINTMENTS VACANT

THE UNIVERSITY OF LEEDS

Applications are invited for posts in the following departments:

SCHOOL OF DENTISTRY-BIOLOGICAL RESEARCH UNIT

RESEARCH LECTURER IN ORAL BIOLOGY

The person appointed to the post should possess a Ph.D. degree or other higher qualification and will be required to carry out research work in the wide and expanding field covering bone, teeth and associated tissues. The appointment will be open to younger graduates who wish to undertake a career in this field.
Reference number 60/7/D.
Closing date May 31, 1970.

PHYSICS

EXPERIMENTAL OFFICER

The successful applicant will be responsible for the day to day operation of cosmic ray recording apparatus, including data reduction using the University's electronic computer. Qualifications: Degree or equivalent in Physics or Electrical Engineering. The post is open to students graduating this year.
Reference number 22/3/D.
SALARY ON SCALE: £995 to £1,460.
Applications (three copies), stating age, qualifications and experience, and naming three referees, should reach the **Registrar, The University, Leeds, LS2 9JT** (from whom further particulars may be obtained), not later than April 6, 1970. Please quote appropriate reference number.

(1260)

CAMBORNE SCHOOL OF METALLIFEROUS MINING (CORNWALL)

Appointment of

LABORATORY TECHNICIAN

for the Mining Laboratories.

Candidates should have had experience in a soil and/or rock mechanics laboratory. Assistance in other aspects such as ventilation will be required. Salary: Technician Grade II, £835 to £965 per annum—it is expected that the appointee would start at the maximum of the scale. The School provides a three-year course leading to the award of an Associateship diploma (A.C.S.M.) which is a degree equivalent.

Applications to be addressed to the Registrar. Tel.: Camborne 2167/2511.

(1243)

ULSTER MUSEUM

Zoological Technician —Taxidermist

Applications are invited for the above post in the Zoology Section of the Natural Sciences Department.

Duties are concerned with the preparation, preservation, and mounting of material for exhibition and for the study collections. Experience of fish-casting in fibre glass an advantage.

At present the Natural Sciences Department is working towards the opening of its new galleries.

Candidates should have Museum Technical Certificate and/or 4 G.C.E. 'O' levels including Zoology or Biology.

SALARY SCALE:

Museum Technician

Grade V—£860 (age 21), £885 (age 22), £910 (age 23), £935 (age 24).
Grade IV—£960 × £990 × £1,020.
Grade III—£1,040 × £1,085 × £1,135 × £1,190.
Grade II—£1,210 × £1,255 × £1,305 × £1,355.

Commencing salary will be decided on experience and age. A Candidate appointed on a lower scale will be eligible for promotion to the higher grades as shown and may eventually be considered for Museum Technician Grade I which has a maximum salary of £1,550.

Application forms may be obtained from the

ADMINISTRATIVE OFFICER,
Ulster Museum, Belfast BT9 5AB.

CLOSING DATE APRIL 30, 1970.

(1242)

SHEFFIELD REGIONAL HOSPITAL BOARD

SHEFFIELD NO. 3 GROUP OF HOSPITALS

REGIONAL MEDICAL PHYSICS DEPARTMENT

Applications are invited for posts in the Basic Grade as PHYSICISTS in the Sheffield Regional Medical Physics Department which is expanding on the commissioning of the new Weston Park Hospital. The posts involve work in radiation physics, radioisotope diagnostic techniques and medical instrumentation. Candidates should possess a good honours degree in physics or its equivalent. The salary scale for the Basic Grade is £1,134 to £1,937 with starting point depending on qualifications and experience. Candidates graduating this summer will be considered.

Applications, naming two referees, to: Chief Physicist, Regional Medical Physics Department, 21 Claremont Crescent, Sheffield, S10 2TA, from whom further details and application forms can be obtained.

(1228)

UNIVERSITY OF TORONTO

DEPARTMENT OF ZOOLOGY

The Department of Zoology invites applications for a post in General and/or Comparative Physiology at the rank of Assistant or Associate Professor, depending upon the applicant's qualifications. The successful candidate will be expected to teach and to develop an active research programme. Salary floors are: Assistant Professor, $10,500; Associate Professor, $12,300.

Inquiries accompanied with a curriculum vitae, may be directed to: Professor F. E. J. Fry, Ramsay Wright Zoological Laboratories, University of Toronto, Toronto 181, Ontario, Canada.

(1173)

ASSISTANT EXPERIMENTAL OFFICER required to collaborate with the Section Head in a detailed study on the effects of herbicides on the microflora of the soil. The candidate will handle a large variety of micro-organisms, using modern microbiological and some biochemical techniques. New microbiological laboratories with good facilities and some technical assistance available. A degree in microbiology or an equivalent qualification is required. Salary in A.E.O. grade (£872 at 21 to £1,208 at 26 to £1,454). For application form and further particulars write to Secretary, W.R.O., Sandy Lane, Yarnton, Oxford, quoting 6/70. Closing date for applications April 18. (1275)

TECHNICIANS or LABORATORY INSTRUMENT MAKERS

with experience of producing experimental apparatus are needed by the Apparatus Section of our Research Department. Inventive capability and a desire to participate in development is called for. The work ranges from devising gadgets and extemporized experimental equipment to constructing precise and complex instruments.

A scientific background is necessary and qualifications to HNC or ONC standard would be advantageous.

Conditions of service include a 5-day week of 37½ hours, Pension Fund, Profit-Sharing Scheme, Restaurant and Recreational Club. Temporary lodging allowances and generous assistance towards removal expenses are offered to married men.

Please apply, quoting reference N/2505 to:
O. Cheesmer, Personnel Department, Imperial Chemical Industries Ltd., Plastics Division, Bessemer Road, Welwyn Garden City, Hertfordshire.

SCIENTIFIC RESEARCH

Government of Canada

A. **RESEARCH LEADER** (Food Additives and Contaminants)—Salary to $23,077—Food Division, Food and Drug Directorate, Department of National Health and Welfare

An experienced scientist of proven ability and leadership is required to direct and supervise a research program concerned with analysis and biochemical properties of food additives and trace contaminants potentially hazardous to man. Present studies include analytical schemes for emulsifiers and flavouring agents, interaction of processing aids with foods, characterization and analysis of fungal toxins, insect metabolites, naturally occurring carcinogens and trace metals.

B. **RESEARCH SCIENTIST** (Poultry Genetics)—Salary to $19,866—Animal Research Institute, Canada Department of Agriculture, Ottawa, Ontario

The preferred candidate will have completed post-graduate training to the Doctorate level in Genetics with particular emphasis on quantitative genetics. Duties will involve collaboration with other scientists on research in poultry egg production, genetics and breeding and on the genetics aspects of a cooperative program on breeding for resistance to poultry leucosis disease complex.

RESEARCH BIOCHEMIST

We have a vacancy in our Biochemistry Department for a biochemist holding a degree or equivalent qualification. The work would be with a senior biochemist, on problems connected with the Central Nervous, or Cardiovascular Systems. Previous laboratory experience would be a distinct advantage.

The modern, well-equipped Alderley Park research laboratories are set in pleasant parkland yet within easy road and rail access to Manchester and London.

Conditions of service, career prospects and assistance available to married men in moving home are designed to attract and retain staff of high calibre, and would be discussed at interview.

Applications, giving brief details of age, qualifications and experience should be sent to:

Mr. P. M. J. Eyre,
Personnel Officer,
IMPERIAL CHEMICAL INDUSTRIES LIMITED,
Pharmaceuticals Division,
Mereside, Alderley Park, Nr. Macclesfield, Cheshire.

Cardiovascular Research

We are looking for a person to initiate research on aspects of cardiovascular disease. His original discipline may be pharmacology, physiology, or pathology. Candidates may or may not be medically qualified, but must have considerable research experience, and preferably hold a Ph.D. or similar qualification.

The successful candidate will become a member of an inter-disciplinary research project team engaged in work on different facets of Ischaemic Heart Disease and Hypertension, their prevention and treatment, and will be expected to develop independent research within the group.

The research staff at Alderley Park is representative of all scientific disciplines pertaining to research on medical and veterinary drugs. Original and fundamental research is encouraged and much freedom is given to the publication of scientific papers.

Conditions of service, prospects, and the assistance given to married men in moving home are designed to attract and retain staff of this high calibre, and would be discussed in detail at interview.

Applications giving brief details of age, qualifications and experience should be sent to:

Mr. P. M. J. Eyre,
Personnel Officer,
IMPERIAL CHEMICAL INDUSTRIES LIMITED,
Pharmaceuticals Division,
Mereside, Alderley Park, Nr. Macclesfield, Cheshire.
